CANELLA ALBA, a tree growing on the coast of many of the West India Islands, particularly Jamaica, also on stony hills; and in woods of the mainland of South America. It was called by Linnæus at one time *Laurus Winteranus*, (*Spec. ed. i. p. 371*), and at another, *Winteriana Canella*, (*Lin. Sp. 636*.) By some it is referred to the Meliaceæ, by others to Guttifera. The bark of the young branches of this tree, freed from its outer rind, is the canella alba of the shops (called also *costus dulcis* and *costus corticosus*, and cortex *Winteranus spurius*, or false Winter's bark). Owing to its white appearance, it has received the name of white cinnamon, which it also resembles in smell as well as cloves. The whole tree is very aromatic, and when in flower perfumes all the neighbourhood; even the dried flowers, when softened again in warm water, have a fragrant odour similar to that of musk. The smell of the leaves resembles that of laurel. The bark is brought to Europe in rolls or quills of two or three feet long, or short broken pieces of from $\frac{1}{4}$ to $1\frac{1}{4}$ inch in diameter, and $\frac{1}{4}$ to 1 line in thickness. The outer surface is either reddish-yellow or verging to a whitish-yellow; the inner surface smooth, resembling the external in colour. The taste is at first agreeably aromatic, and somewhat bitter; afterwards acrid and peppery.

According to Petroz and Robinet, it contains a very acrid aromatic volatile oil (which Sloane says is heavier than water, Henry lighter, and which is employed for the adulteration of oil of cloves), a bitter extractive, a resin, a sort of manna sugar, called *canellin*, gum, albumen, and starch. It is rarely, if ever, adulterated, but is itself often substituted for the *Drymis Winteri* or true Winter's bark. The two may be distinguished by the following characters:

Canella Alba.

Of a pale orange or ash colour.
Fracture whitish, marbled.

Winter's Bark.

Grey or reddish-grey.
Fracture compact or foliaceous, grey at the circumference, red towards the centre, with a very obvious line of demarcation.

Internal surface covered with a whitish pellicle.

Internal surface of a deep red or black.

Canella Alba.

Odour agreeable, resembling cloves.

Taste acid, bitterish.

Powder white.

Watery infusion pale.

The cold infusion of each, treated with the following reagents, conduct themselves thus:

	<i>Tincture of Galls.</i>	<i>Muriate of Iron.</i>
Canella Alba.	Slight whitish disturbance.	Brown yellow discoloration.
Drymis Winteri.	No action.	Dark brown discoloration.

	<i>Sulphate of Iron.</i>	<i>Nitrate of Barytes.</i>
Canella Alba.	No action.	No action.
Drymis Winteri.	Precipitate.	Precipitate.

Alcohol is the most appropriate menstruum: water takes up the less powerful principles only. As the infusion is not affected by many articles which it is often desirable to give at the same time, it affords an eligible vehicle for these, such as tincture and infusion of galls, lime-water, tartar emetic, and the salts of iron and mercury. It may also be given in powder. From its aromatic properties, it is likewise a suitable adjunct to mere bitter infusions, such as those of gentian. In the dyspepsia, attended with constipation, of sedentary people, along with sulphate of iron, aloes, and sulphate of potass, it is a most efficacious medicine.

CANES VENATICI, the Hounds, a constellation added by Hevelius, who called the nearest to the pole Asterion, and the other Chara. They are held in a string by Bootes, and are surrounded by Bootes, Coma Berenices, and Ursa Major. (See also **COR CAROLI**.)

CANG or **KEA**, a large wooden collar used as an instrument of legal punishment by the Chinese. It is a species of walking pillory, fitting close round the neck of the culprit, and of such a weight that he can carry it, though with pain and difficulty. The weight is proportioned to the nature of the offence; but the cang most commonly in use weighs from 50 to 80 pounds. When it is fastened round the neck, two long slips of paper are pasted over the two parts of the cang, which opens and shuts like our stocks; on these papers the mandarin puts his seal, so that the parts cannot be separated or the criminal relieved without its being perceived. The crime for which he suffers and the duration of his punishment are then inscribed on the cang in large letters, and the officers of the police parade the criminal through the town, after which he is left exposed in some much frequented street or square, or at one of the gates of the city. As the cang prevents his making any use of his hands, he must be fed by others. A recent writer, who has lived long in China, says that this awkward, galling, torturing wooden collar, which is removed neither by night nor by day, is sometimes worn for a whole month (*The Chinese*, by John Francis Davis, Esq.), and, according to older authorities, or the Jesuit missionaries, it was not unfrequently worn for three months together. The Chinese consider this species of punishment very infamous and degrading. A correct representation of the instrument and the manner in which it is applied are given in Sir George Staunton's account of the Chinese, and in the work of Mr. Davis. The cang, called by them Tahtakulah, was formerly in use among the Turks. [**BASTINADO**.]

CANGE, CHARLES DUFRESNE SEIGNEUR DU, was born at Amiens in 1610. He studied the law, but after a time gave himself up entirely to history and philosophy. His first work was '*Histoire de l'Empire de Constantinople sous les Empereurs François*,' fol. 1657. But he is better known for his '*Glossarium ad Scriptores mediæ et infimæ ævæ*,' 3 vols. fol.; afterwards republished in 6 vols. in aramoni.

Winter's Bark.

Odour peppery, and, when powdered, turpentine-like.

Taste sharp, burning, intolerable.

Powder greyish yellow.

Watery infusion red.

1732, to which were added 4 more vols. by Carpentier, a Benedictine of the order of Cluni. It is a most useful work for the understanding of the numerous writers of the dark or middle æge, when for many centuries a corrupt and barbarous Latin was the literary language of Europe. All the words used by the writers, which are not found in classical latin, are given in alphabetical order, with their various meanings, their etymology, and references to the authorities. This work is also useful for understanding old charters, and other legal documents of an early date. The labour and research required for the compilation of such a work can be best appreciated by those who have frequent occasion to consult it. Ducange was one of the editors of the '*Corpus Historiæ Byzantinæ*.' He died in 1688. Louis XIV. bestowed a pension of 2000 francs upon his children. [**BYZANTINE HISTORIANS**.] He wrote also: 1. '*Historia Byzantina illustrata*,' fol., 1680, being an historical description of Constantinople and its monuments, with biographies and genealogies of several distinguished families of that city. 2. '*Glossarium ad Scriptores mediæ et infimæ Græcitatæ*,' Paris, 1688, 2 vols. in fol., a work that is very necessary for those who are studying the lower Byzantine writers. He left a vast quantity of MSS., especially on historical, archæological, and genealogical subjects, which have been collected in the national or royal library at Paris, and of which an account is given in the *Mémoire historique sur les MSS. de M. du Cange*, Paris, 1752. Ducange is often quoted by the name of Du Fresne, under which he is also registered in many catalogues.

CANIS. [Dog.]

CANIS MAJOR, the Greater Dog, a constellation which contains SIRIUS, the brightest star in the heavens, called also the Dog Star. To this article we shall refer all historical and mythological information connected with this constellation, it being in fact the star, and not the constellation, about which we shall have to speak.

This constellation is directly found by the bright star Sirius, which is in the continuation of the line drawn through the belt of Orion. The surrounding constellations are Argo, Monoceros, Orion, Lepus, and Columba Noachæ. At the end of January, Sirius is on the meridian at midnight. The letters in parentheses are not Bayer's (*Baily's Flamsteed*.)

CANIS MINOR, the Lesser Dog, a constellation above the Greater Dog, and distinguished by a star of the first magnitude, Procyon, which see for information connected with the history of this constellation. It may be found in the heavens thus: draw a line through Orion's belt and Sirius; a perpendicular to this line from Sirius upwards will pass through Procyon, which is too large a star to be mistaken. It is also nearly in the line joining Sirius and Pollux, about midway between them. The letters in parent

IR. This term is applied, perhaps not with strict propriety, to a very serious disease of the foot of the horse. The horn having been separated from the sensible portion of the foot, a fungous substance is produced instead of new and healthy horn. The treatment, however, is exceedingly simple. Every portion of horn that has begun to detach itself must be removed. Some superficial caustic must then be applied in sufficient quantity to repress the growth of the fungus, and to rouse the exposed surface to healthy action, but not to eat into and corrode the foot. The butyr (protochloride) of antimony is the best agent for accomplishing these purposes; for, being speedily decomposed by the moisture of the part, it can only act as a superficial caustic. The fungus having been repressed, the Friar's Balsam may succeed as a mild stimulant to the secretion of good horn. No ointment should touch the cankered foot; but pledgets of soft and clean tow should be placed over the sore, and bound firmly upon it, making as equable a pressure on every part of it as can possibly be effected. The foot should be dressed at least once in every day, and kept as dry as circumstances will allow.

Inflammation of the internal part of the ear of the dog will sometimes produce a fungous ulceration, to which also the term *canker* has been applied. A dog may be observed to be continually shaking his head, or scratching his ear, or carrying his head on one side. If the part is examined, some degree of redness or enlargement of the irregular projections on the inside of the ear will be seen. This will generally yield to a few washings with warm soap and water; but should actual ulceration have commenced, a drachm of the extract of lead should be added to half a pint of a decoction of the heads of white poppies, and this substituted for the soap and water. The inflammation beginning to subside, a scruple of alum should be added to this lotion, in order to dry up the ulcer; but nothing stronger than this should ever be applied, and even the alum should be cautiously added, in proportion as the dog is able to bear it. Purging and alterative medicines will be useful auxiliaries.

If the case is obstinate, and the ear begins to be extensively ulcerated, and the ulcer spreads over the flap of the ear, a seton should be inserted in the poll precisely between the ears, and extending from ear to ear. All water-dogs are particularly liable to this species of canker.

There is another variety of canker belonging to the flap of the ear to which the hound and the pointer are especially subject. It is either the consequence of that which has been just described, or exists independently of it. A sore appears on the edge of the flap of the ear of a true cankerous nature, and corrodes the very cartilage. The treatment of this also is simple and effectual. The ears, or at least the diseased part, should be confined by a cap of leather or strong calico, so that the dog can flap and beat his ear, it is evident that the ear can never heal. This being contrived, a strong ointment of alum or white vitriol (sulphate of zinc), or both combined, should be well rubbed on the sore morning and night. The simple alum ointment should first be tried.

Sportmen too often round the ears of the dog; that is, they cut off the diseased parts. This disfigures the animal, and is rarely effectual. Either a new ulcerative inflammation is set up by the operation, or the whole ear having been isolated and separated from the old

wound, the peculiar ulcer of canker speedily appears again as extensive and as obstinate as before.

CANNA. [ANTELOPE, Species 57, 58.]

CANNABIS (in Greek *Κάναβις*, and in Latin also the same, *Cannabis*), the genus of plants that yields the substance called hemp. *Cannabis sativa*, or common hemp, is a plant nearly allied botanically to the nettle, with which it even agrees in its general appearance. It is an annual diocious plant, with erect nearly simple stems from four to six feet high, and covered with rigid hairs. The leaves are either alternate or opposite, digitate, and stalked; the leaflets are five in number, narrow, lanceolate, sharp-pointed, serrated, rough, pale-green on the under side; the uppermost leaves have only three leaflets. The male flowers grow in little bunches at the axils of the upper leaves; they are pendulous from short stalks, and have a calyx of five spreading, narrow lanceolate sepals containing five stamens. The female flowers appear in close, leafy clusters at the axils of the upper leaves, and consist of a roundish calyx split half-way down into two parts, and containing a simple one-celled ovary terminated by a couple of awl-shaped stigmas. The fruit is a lenticular body, looking like and commonly called a seed.

This is the only species known; it is said to be a native of Persia, and is certainly wild, according to Roxburgh, 'among the hills and mountains north of India, as well as common everywhere in the gardens of the natives throughout Asia.' It is now universally distributed over the north of Europe. Herodotus, iv. 74, describes it as growing in Synthia, N. of the Danube, a country which he had visited. We must from this conclude that the plant is really a native of north and east Europe.

It is from its possessing a remarkably tough kind of woody tissue capable of being manufactured into linen and cordage, that hemp is best known; and for its good qualities in this respect it is unrivalled among the many species possessing similar properties in the nettle tribe [URTICACEÆ]. But it also contains a deleterious narcotic secretion of great energy. If one remains for any length of time amongst a plantation of young hemp, head-ache and vertigo are often the result; in hotter countries these effects are much more violent, a kind of intoxication being speedily produced. Oriental nations have taken advantage of this to add another to the list of intoxicating drugs, which they contrive to substitute for the forbidden wine of western people. The powdered leaves, mixed with some kind of aromatic, are infused in water, and drunk, when a drowsy ecstatic feeling comes on, which is said to be much more agreeable than that produced by opium. The leaves are also mixed with tobacco for smoking. The two chapters of Herod. iv. 74, 75, are curious, as to its intoxicating effects, &c. The drug obtained from hemp is called bang, or hashish, or cherris: *ganjika*, or *ganga*, *kinnab*, *subjah*, *majah*, are other names for it. The seeds of hemp abound in a thick mucilage, and are used medicinally for the preparation of emulsions; a useful oil is obtained from them by pressure.

CANNÆ. [HANNIBAL.]

CANNÆ. [MARANTACEÆ.]

CANNES, a town in France, in the department of Var, on the coast between Frejus and Antibes; 24 miles from Frejus, and about 10 from Antibes. Of the houses, some are built in a line along the shore, having the space which separates them from the sea planted and laid out as a promenade; those in the back part of the town are clustered on the tolerably steep slope of a hill, which is surmounted by an ancient castle, no longer used as a place of defence. The only defence of the town consists in a battery, the guns of which bear upon the sea. Cannes has neither harbour nor roadstead; but only a small bay or cove so shallow that the coasting vessels that use it are obliged to anchor at some distance from the shore, exposed to the full action of the swell. Yet with this disadvantage, Cannes is for its size a populous and busy town. Its commerce is in the anchovies and sardines caught by the fishermen of the town (of these fish the town's people sell on an average 2000 quintals (100 lbs. each) per year), and in the wine, oil, oranges, lemons, figs, &c. produced in the neighbouring district. Cannes is one of the places of France where the culture of the lemon is most successful. Population, in 1832, 3726 for the town, or 3994 for the whole commune. Expilly (A.D. 1762) computed the population at 5000.

Opposite the headland which forms the eastern bay of the gulf of Napoule, on which Cannes is situated.

the Isles of Ste. Marguerite (in the castle of which, used as a state prison, the prisoner with the iron mask was confined), St. Honorat.

Napoléon landed at Cannes on his return from Elba to France in 1815.

CANNIBALS, Anthropophagi, or men-eaters. In the *Odyssey* of Homer we have the story of Polyphemus devouring human flesh; and in Herodotus, the Massagetæ (i. 216) are said to eat their aged parents. The Padmæ of India (Herod. iii. 99) were in the habit of killing and eating their relations when they fell ill; a story which some would reject with as little show of reason as others would believe it. Modern facts, the truth of which is put beyond all doubt, confirm the statements of Herodotus. Among the antient Tupis of Brazil, when the Pajé (chief) despaired of a sick man's recovery, he was by his advice put to death and devoured. (Dr. Martius in *London Geog. Journal*, ii. 199.) [See also BATTAS.] Herodotus (iv. 26) also says that among the Issedones, when a man's father dies, his relations come and help to eat the dead man, whose flesh they render more palatable by mixing it with that of some animal. That these facts as to cannibalism, as reported by antient writers, are not to be hastily rejected, need hardly be remarked.

In the middle ages, it is true, these stories of cannibalism were wonderfully enlarged, and people who had not yet embraced Christianity were pretty generally set down as anthropophagi. When the Lombards invaded Italy at the end of the sixth century, it was reported of them that they ate human flesh; and a century later the same aspersions were cast on the Sclavonian tribes. It became the fashion to bandy the accusation between enemies; thus, during the Crusades, the Saracens said the Christians ate human flesh, as well as the unclean flesh of swine, while the Christians on their side maintained that the Saracens ate men, women, and children, and were particularly fond of a sucking Christian babe torn fresh from the breast of its mother. The giants and ogres of our nursery tales are only the Saracens of the holy wars seen through the magnifying glasses of tradition and romance.

It is not much surprise us that in those rude ages men should try to fix a revolting practice on their sworn foes, but we can hardly understand why the minstrels of the Christians should convert their most approved heroes into cannibals, and praise them for the quantity of infidel flesh they devoured. Yet our Richard I. is put in this predicament by the author or authors of the romance of 'Richard Cœur de Lion.' According to the poem, the first symptom of the king's recovery from a dangerous sickness at Acre was a violent longing for pork, and as pork was difficult to procure in a Mohammedan country, his cook dressed him a Turk's head, of which Richard ate with good appetite, and felt quite well in consequence. After some more repasts of the same kind, he is made to say:—

King Richard shall warrant,
There is no flesh so nourissant
Unto an English man
Partridge, plover, heron, no swan,
Cow, no ox, sheep no swine,
As the head of a Saracen!

The old travellers abound in stories of cannibalism, which we may almost invariably pronounce to be false. Few persons would now credit that the Indians and Chinese sold human flesh in the market, or that the Grand Khan of Tartary fattened his astronomers and magicians with the carcases of condemned criminals; but Marco Polo, the Venetian, who resided in China and traversed the Indian seas in the 13th century, in speaking of a people in Sumatra (the Battas), and of the fierce inhabitants of the group of islands called the Andamans, relates no more than has been confirmed by modern travellers.

In the 16th and 17th centuries, the wildest accounts of the natives of the newly found lands in America, and of places on the African coast recently brought within the range of European commerce, were circulated by ignorant sailors and believed by credulous writers. In many of these cases there was a small matter of truth at the bottom, which was wonderfully magnified by fear and credulity. It was reported, for example, that the Caribbees preferred sucking infants to all other food—that the Peruvians kept mistresses for the purpose of breeding children for their tables, and fattened, killed, and ate these women when they were past child-bearing—and, not to mention numerous other instances, that the Amangas of South Africa exposed human

flesh for sale in their shambles, as we do beef and mutton. The industrious and compiler Purchas says he was assured of the truth of the latter story by 'the Gentleman of Essex, a man of some estate and a man of good credit.' Even in modern times the inhabitants of Van Diemen's Land have been accused of cannibalism, in Dentrecasteaux's Voyage, because the bones of a kangaroo were mistaken for those of a young man.

Many persons, who admit that human flesh has been eaten under the pressure of necessity, as in sieges, shipwrecks, &c., still maintain that there is no evidence of any race or people eating human flesh from choice. But proof the most conclusive has been brought against the New Zealanders, who devour their captives taken in war in the most open manner. It is also stated on good authority that even the New Zealanders who had been civilized by intercourse with Europeans and their voyages, when European ships resumed their habits of man-eating, as they returned home. That the horrid practice is on the decline in New Zealand is proved by the captain of the French navy, who very recently staid months at the island. (See *Voyage de la Favorite, de l'année 1830 à 1833*, par M. Laplace.)

The Battas of Sumatra have already been instanced as undoubted cannibals, and there are still native tribes in Guiana, in South America, who fatten and eat their prisoners (*London Geog. Journal*, vol. ii. p. 70; but compare vol. ii. p. 240.)

We refrain from offering any conjecture as to the origin of cannibalism. No explanation that we have seen appears to us satisfactory.

(*History of Sumatra*, by William Marsden, F.R.S., p. 300; *Memoir of the Life and public Services of Sir T. Stamford Raffles*, by his Widow, vol. ii., p. 77; Volume on the *New Zealanders*, in the *Library of Entertaining Knowledge*.)

CANNING, GEORGE, was born on the 11th of April, 1770, in the parish of Marylebone, London. His descent on the paternal side was from an ancient family, his ancestors having figured at different periods at Bristol, in Warwickshire, and in Ireland.

Canning's father died in 1771, when his son was only a year old. His mother, who was afterwards twice married, lived to see her son occupy a high post in the government. The means of defraying Canning's education were furnished by his paternal uncle, a merchant in the city of London; but some slight funds are said to have proceeded from a small estate in Ireland which fell to him. George Canning was first sent to Hyde Abbey school, near Winchester, whence he was removed to Eton. He had begun to write English verses when very young, and at Eton, in his sixteenth year, he formed the plan of a periodical work called 'The Microcosm,' which was written by himself and three schoolfellows, and published at Windsor in weekly numbers from November, 1786, to August, 1787. In October, 1787, Mr. Canning was entered as a student of Christ Church, Oxford, where he gained some academical honours by his Latin poetry, and cultivated that talent for oratory which he had begun to display at Eton. At Oxford Mr. Canning made the acquaintance of Mr. Jenkinson, afterwards Earl of Liverpool, who is supposed to have been of service to him in the political career on which Mr. Canning entered immediately after leaving college. His college vacations were chiefly passed in the house of Mr. Sheridan, who took a lively interest in his fortunes, and introduced him to Burke, Fox, Lord John Townsend, the Duchess of Devonshire, and other leading persons, who were almost exclusively of the Whig party in politics. It has generally been stated that it was by the advice of Sheridan that Mr. Canning, who had entered of Lincoln's Inn, gave up the study of the law, and devoted himself to a political career. From his intimate connexion with Sheridan it was expected that he would adopt that gentleman's political opinions and the opposition; but Mr. Canning accepted the views of the Tory party, and was brought into parliament with Pitt in 1793. One of the biographers of Mr. Canning, without pretending to determine the point, offers, as an hypothesis, to account for Mr. Canning's adoption of the Tory party, that he might have seen 'the difficulties which he would experience in rising to the full growth of his ambition under the shadowy branches of the Whig aristocracy, and that superseding influence of birth and connexions which had contributed to keep such men as Burke and Sheridan out of the cabinet.' (Moore's *Life of Sheridan*.) Mr. Can-

the first care was to himself maintain
the de- not
addressed

the style and manner of powers
as commanded respect and go he subject
of the debate on which he spoke Featy (coupled with
of Sardinia from England) with the Sardinia
enable his majesty to resist the invasion of mont by the
French. During that session and the session of 1795 Mr.
Canning spoke frequently, and at times was left by Mr.
Pitt to bear the brunt of a formidable debate. At this time
he supported the temporary suspension of the Habeas
Corpus, and declared himself against parliamentary reform.

In 1796 Mr. Canning became under secretary of state,
and in a general election in that year he was returned for
the borough of Wendover, Bucks. For two years
his attention was chiefly confined to the duties of his office.
In 1798 he expressed himself in favour of Mr. Wilberforce's
motion for the abolition of the slave-trade, and in a speech
which produced a very considerable effect in the house, he
replied to Mr. Tierney's motion for recommending George
III. to make peace with the French republic, then in the
full career of conquest and spoliation. In the autumn of
1797 Mr. Canning, in conjunction with Mr. John Hookham
Frere, Mr. Jonkinson, Mr. George Ellis, Lord Clare, Lord
Morpington (now Marquis of Wellesley), and one or two
other social and political friends, started a paper styled
'The Anti-Jacobin,' the object of which was to attack the
journalists and other writers of the day who advocated or
were supposed to advocate the doctrines of the French revolution.

Mr. Gifford was appointed editor of this weekly paper,
but Mr. Canning wrote the prospectus, and from its commencement, in November, 1797, to its close in 1798, he contributed largely to it. Some of the best of the poetry, burlesques, and *jeux d'esprit* were from his pen. (*Poetry of the Anti-Jacobin*, 1 vol. 8vo.)

When the subject of the Irish union was brought before
parliament Mr. Canning repeatedly spoke at great length
and with much effect in support of that measure. In 1799
he was appointed one of the commissioners for managing
the affairs of India; and in 1800 he married Joanna, the
youngest daughter of general John Scott, of Balcombe, an
officer who had acquired great wealth. This union made
Mr. Canning perfectly independent of place, for his wife's
fortune exceeded 100,000*l*. On the dissolution of Mr. Pitt's
cabinet in 1801, Mr. Canning retired with the rest, and for
several successive sessions his declamation, wit, and keen-
ness of irony, lent a formidable strength to the opposition
arrayed against the Addington administration. On Mr.
Pitt's return to office, in 1804, Mr. Canning was named
treasurer of the navy.

In 1805 he defended Lord Melville, the ex First Lord of
the Admiralty, who was accused by Mr. Whitbread and
others of having made an unfair use of public money. Can-
ning's defence of his friend was eloquent and skilful, but it
failed. Mr. Pitt died in January, 1806: in February there
was a complete change of ministers, and Mr. Canning was
made by Mr. Sheridan as Treasurer of the Navy. In
1807, Mr. Canning again accepted office, and was
Secretary of State for Foreign Affairs in the new
cabinet headed by the Duke of Portland. Of all the depart-

ments of government, this was probably the one he was best
qualified to manage; his dispatches were lucid, manly, and spirited,
and many of his state-papers are models of that kind of
composition. On the 21st of September, 1809, Mr. Canning
fought a duel with his colleague Lord Castlereagh. The
question which arose out of the Walcheren expedition, and
the resignation of the Duke of Portland and Mr.
Castlereagh, as well as of Lord Castlereagh. Mr. Canning
had been in favour of Catholic emancipation, and on the
11th of April, 1812, he eloquently supported Mr.
Grattan, who moved that the Catholic claims should be re-
ferred to a committee of the whole house. Again, on the
22nd of June, 1812, Mr. Canning moved that the House
should take the Catholic question into consideration early
in the next session, and the resolution was carried by a
majority of 139. Whoever looks back through the long
history of Catholic emancipation, will see how largely the
final success of that measure was owing to the untiring
exertions and eloquence of Mr. Canning, who unhappily

died a short time before it could be carried, and left
honour to his opponents. He had been through life its most vio-

Parliament being dissolved in 1812, Mr. Canning was
elected for Liverpool, which also returned him in 1814, in
1818, and again in 1820. In October, 1814, he was sent
Ambassador to the Prince Regent of Portugal, an appoint-
ment which was afterwards the subject of severe animadver-
sion in parliament. In the autumn of 1816, he became
President of the Board of Control. During the session of
1819 he again expressed his decided hostility to parliamen-
tary reform. In June, 1820, when the conduct of Queen
Caroline, the wife of George IV., was brought before parli-
ament, Mr. Canning rather than bear any part in the
proceedings resigned his office, and went to make a tour on
the Continent. During the session of 1821 he again sup-
ported the Catholic claims with his usual warmth; and in
the session of 1822 he again opposed parliamentary reform.
In the course of the latter year he was named Governor-
General of India, and having made all his arrangements
for leaving England, he was at Liverpool to take leave of
his friends and constituents, when Lord Castlereagh (then
the Marquis of Londonderry, and at the head of foreign
affairs) committed suicide on the 12th of August, 1822.
On the 16th of September following, Mr. Canning, who had
been entreated to give up his much more profitable Indian
place, was again appointed Secretary of State for Foreign
Affairs. Declining to interfere in the troubled state of
Spain, where 'the spirit of unlimited monarchy, and the
spirit of unlimited democracy' were in fierce collision, Mr.
Canning turned his attention to the new world, and came
to the resolution to send out consuls to the principal states
of Spanish South America. This was a preliminary to the
recognition of the independence of those new governments,
which, though totally unsettled, were *de facto* free of Spain.
Early in 1825 he formally notified to Europe that the
British government would appoint diplomatic agents to
Columbia, Mexico, and Buenos Ayres; and concluded treat-
ies of commerce with those States on the basis of the re-
cognition of their independence. In December, 1826,
carrying the sense of the House almost unanimously
along with him, he announced the intention of government
to prevent Spain, who had lost her constitution, from inter-
fering with Portugal whose constitution still lingered on,
between life and death; but he protested at the same time
that the British troops were to go to Lisbon, 'not to rule,
not to dictate, not to prescribe constitutions, but simply
to defend and preserve the national independence of an
ally.'

On the 18th of February, 1827, the Earl of Liverpool, the
premier, becoming incapacitated, on the following 12th of
April Mr. Canning was appointed his successor. No
sooner was this appointment announced, than the Lord
Chancellor (Eldon), the Duke of Wellington, Lord Bathurst,
the Earl of Westmoreland, Viscount Melville, Lord Bexley,
Mr. (now Sir Robert) Peel, with various members of the
household, resigned in a manner which showed decided hos-
tility to the new premier. George IV. wished to form a minist-
ry precisely on the principles of that of Lord Liverpool, but
these numerous resignations made the scheme impossible,
and Mr. Canning commenced (or possibly only concluded)
a negotiation with the Whigs, which ended in the admission
of several of that party to office, and in the promised support
of others, at the head of whom were Mr. Brougham, Mr.
Tierney, and Sir Francis Burdett. The opposition to the
new premier in the House of Commons was of a most for-
midable and irritating character; but though he was labour-
ing under anxiety and sickness, his rhetorical powers and
his sparkling wit never failed him. It was in these speeches
that he repeated his determination to oppose parliamentary
reform, and declared himself hostile to the repeal of the
Test and Corporation Acts. "On the Test Act, however, he
had never before fully delivered an opinion to the House;
and his opposition to its repeal, or the agitating that ques-
tion then, may be said by those, who in other respects ap-
prove of Mr. Canning's political career, to have arisen out
of a fear of complicating and prejudicing the Catholic
question. Conceding however to Mr. Canning his full
share of merit for his exertions in favour of Catholic em-
ancipation, we cannot admit that he had those enlarged
views of social reform, nor those powers and acquirements
which entitle him to be considered a great statesman. Mr.
Canning spoke in parliament for the last time on the 29th

June, 1827, three days before a treaty combining Russia, for the settlement of the affairs of Greece, and of which he had been the main promoter, was signed at London. This was the last of Canning's public acts; one of the first poems he wrote in the enthusiasm of youth, was a lament on 'The Slavery of Greece.' About the middle of July, Mr. Canning retired for change of air to the Duke of Devonshire's Villa at Chiswick, where he died on the 8th of August, 1827.

CANNON. The manufacture of cannon is very simple. They are not cast hollow, for it is found that, if so cast, they will not be equally strong in every part, on account of the irregularity in the cooling of the metal. They are therefore cast solid, and thus the outside cools first, with the grain close and sound; while the centre cools last, and the porous or spongy parts consequently are all found in the centre.

The cannon is then put into a lathe with the breech towards the mandril, and the centre of the mouth-end resting on the back-centre of the lathe; the outside of the muzzle is then turned sufficiently to rest in a boring-collar, i.e., a circular hole in a support that is subsequently placed in the lathe. After turning the muzzle, the back-centre is removed, and the boring-collar is pushed against the muzzle and supports it: a long drill is now put to the centre of the mouth, the other end of the drill being either supported by the back-centre and driven forward by the screw, or the drill is supported on a rack, and advanced by a pinion and weight. The lathe being put in motion, the cannon revolves, and the drill bores it to the required size.

Some experiments have lately been made to enlarge the calibre of cannon without enlarging their external dimensions, and some 18 pounders have been bored to carry 32 lb. ball; but in this case it is intended only to throw the ball a short distance.

A method of loading guns at the breech has been proposed, by Mr. Tucker:—the gun is bored completely through the breech, and a perpendicular hole is bored at a short distance from the breech; into this hole a strong plug is well fitted by grinding, the plug having a hole through it of the same size as the bore of the gun—the arrangement in fact is just like a common water-cock. When the holes coincide, the cartridge is thrust through the breech, and the plug being turned half round, the gun is charged. A practical objection to loading cannon, or even fowling-pieces at the breech is, that however well the joints may be made they do not long continue tight, the powder inevitably finding its way through.

CANNSTADT, a bailiwick in the Würtemberg circle of the Neckar; with an area of about 31 square miles, and 22,200 inhabitants; one town and five villages and hamlets. It is traversed by the Neckar, and contains several mineral springs and baths, and many Roman antiquities. The chief productions are wine of excellent quality, madder, maize, and tobacco; it manufactures yarns and cottons; and rears cattle.

The town of Cannstadt is on the Neckar, nearly in the centre of the kingdom, and in the bosom of a fertile and beautiful country. It contains about 390 houses, and about 4050 inhabitants. Independently of its trade, for it is the staple town for the traffic in the Neckar, and has manufactures of woollens, cottons, tobacco, &c., there are 37 mineral springs in the neighbourhood and a regular establishment of baths, with grounds laid out for visitors. The Seelberg, an adjoining hill, 640 feet in height, contains fossil remains of the mammoth and rhinoceros, and teeth and bones of unknown animals. Vases, coins, and other Roman antiquities have of late years been found near Cannstadt. The two royal seats, Bellevue and Rosenstem, are in its vicinity. 48° 28' N. lat., 9° 13' E. long.

CANON (*κάνων*), a rule. The several senses in which this word is used are all derivatives from its first or original sense; and this sense it appears to have acquired, as itself a derivative from *canua*, (we use the Latin form, though in fact both *canua* and *cunon* are Greek terms transplanted into the Latin language,) which signifies a *reed* or *cane*; such a plant as produced straight, round, smooth and even shoots, adapted to the purpose of a *rule*; or as we say, a *ruler*, used in drawing straight lines. The word *cannon* is the same with *canon*, and is applied to the instrument of war used on account of its resemblance to a rule. The word is used in mathematics and in music; and also to

express certain grammatical rules formed by the critics. But it is more particularly appropriated to rule in respect of things ecclesiastical, and it is in this application of it that we are now chiefly and chiefly to be considered.

If it is asked why *canon* should be used for *rule* especially in things ecclesiastical, we answer that the most probable reason that can now be given is, that the word was so used by Saint Paul (Gal. vi. 16). And as many as walk according to this rule (*canon*), peace be on them and mercy, and upon the Israel of God.

The rule here spoken of was the Christian rule, the rule or law of the Christian church; and as these rules became explained or amplified in subsequent times by persons deemed of authority in the church, as by popes, bishops, councils, whether general or particular, these rules or explanations of the ancient and fundamental rules of the Christian church were designated by the term *canons* or *canons*. Of these there is a great multitude, and they speak of the canons of the Council of Nice, the canons of the Council of Trent, meaning the decisions of those councils on points of doctrine or discipline submitted to them. The *Apostolical canons* are canons which are supposed to have been agreed upon at a very early period in the history of the church. By some learned persons they have been referred even to the times of the Apostles, whence this name.

The collected body of these canons forms what is called *The Canon-Law*, which in other words is the law of the church, that body of injunctions regulating men's private discipline, and their social relations, which originate not in the conferences and wills of civil authorities or parliaments, but in the deliberations of ecclesiastical courts or ecclesiastical assemblies, the members of which were ecclesiastics, and the precedents on which they acted the decrees of similar assemblies, or of other persons possessing ecclesiastical authority, or finally, of the most sacred authority of all, that of the Apostles and of the Founder of the Christian church. We may here make a slight deviation from our subject to point out the distinction between the canon law and the civil law. The former is already explained. The civil law is the political and municipal law of the Roman empire. When we hear a person spoken of as doctor of laws, what is meant is, that he is a doctor of both civil and canon law; but the term in Great Britain is now little more than a mere honorary distinction.

Canon is also used for the *rule* of persons who are devoted to a life strictly religious: persons who live according to (religious) rule, such as praying at certain hours, and for a certain length of time, keeping themselves from marriage, eating particular kinds of meat, periodical fastings, and the like. It is applied to the *book* in which the rule was written, and which was read over to such professed persons from time to time: and since in such a book it was not unusual to enter also the names of persons who had been benefactors to the community, which names were recited from time to time with honour, and they were held and reputed to be holy persons or saints (*sanciti*); the entry of such names formed what is meant by *canonization*, though in later times, when it was found that saints multiplied too fast, when every small religious community added any benefactor to their list, the term became confined to such persons as had their names enrolled in the great imaginary volume of which the head of the church was the sole guardian. It was also applied to persons who lived under a rule; as the Augustinian canons, persons who adopted the rule of Saint Augustine. And hence the distinction is to be observed of *regular* and *secular* canons. The regular canons were persons who were confined to their own monasteries, where they practised their rule; the secular canons were persons living indeed a religious life, or one according to some prescribed Christian form and order, but who nevertheless mixed more or less with the world, and particularly as discharging the various offices of civility for the edification and benefit of the church. This was the species of canons that are found in the great churches, or in other churches called conventual, as at Southwell in Nottinghamshire, which were all churches of very ancient foundation, the centres of Christianity throughout an extensive district. There they lived a kind of monastic life under the presidency generally of a bishop; but issuing forth from time to time to introduce the light of Christian truth into districts into which it had not before penetrated, or to instruct the persons lately received into the church, and to perform for them the various ordinances

of Christianity. As parish churches across the necessity for such visits from the canons in the cathedral churches was diminished. But the institutions remained: they were altered at the Reformation and reduced to the present state. These canons are sometimes called *prebendaries*. This arises from their being endowed with land as *tithe*, as many of them are to a greater or less extent, which endowment is called a *prebend*. The canons have stalls in the cathedral churches, which are generally *prebendal stalls*. They form the chapter in the cathedral, with the dean and chapter, and are still nominally what they actually once were, the council of the bishop for the administration of the affairs of his diocese.

CANON is formed *canonical*, which occurs in many ecclesiastical terms, as *canonical hours*, *canonical sins*, *canonical punishment*, *canonical letters*, *canonical obedience*, *canonical scriptures*. These terms require no explanation, except it be to add that the canonical scriptures are the usually received books of the Old and New Testament.

CANON, in music (*κανών*, a *rule*), a composition, generally vocal, sometimes in two, but commonly in more parts, in which, with the exceptions that will be mentioned, precisely the same melody, or subject, is given to every part. This melody is sung by each, after the leader, either on the unison, or the octave, or on the fourth and octave, &c., below, the voices severally following or answering each other at the expiration of one or more bars. According to many German and French writers the canon is a *perpetual fugue*, but this definition is liable to great objection: indeed, the term *fugue* is itself by no means satisfactory. [FUGUE.]

To compose a canon on the unison, or octave, requires less labour than genius, and, with very few exceptions, is the only composition of the kind that produces a constantly agreeable effect. A canon is said to be written *three-in-one* (or *four-in-one*, &c.) on the unison, when the parts follow on the same degree of the scale. Cherubini's 'Peregrina Clori,' and Dr. Hayes's 'Come follow me to the greenwood tree,' are admirable examples of this sort. The renowned 'Non nobis, Domino,' of Birde is an unrivalled specimen of the canon three-in-one, on the fourth and octave below; and Dr. Blow's 'Gloria Patri' (engraved on his monument in Westminster Abbey), a canon four-in-one, on the fifth, octave, and twelfth below, is entitled to the encomiums that have been bestowed on it.

A canon in many parts may have two or even more melodies. Thus a canon four-in-two is for four voices, two singing one melody, two another, both subjects blending. But the canon takes numerous shapes, though it would be a waste of room and time to describe one-tenth of them. The *Canon by Augmentation* is that in which the notes of the answers are double and quadruple in length those of the subject. Dr. Cooke's 'Amen' (regularly sung after 'Non nobis' at the Catch-Club) is an ingenious example of this species. The *Canon by Diminution* is exactly the reverse of that by augmentation. The canon *Recte et Retro* has but one peculiarity, and pretends to only one merit, namely, that it may be sung either forwards or backwards—it is worthy to be sung by those who suffer from excess of leisure, or have no musical ear, or feel the necessity of doing penance. And here we cannot forbear expressing a regret that any composer of real talent should have passed days and nights in the mechanical drudgery of generating such uninteresting snappings as all canons, except those in the unison, are. In schools, as exercises for youth, they may be of some use; but even there, if much importance should be attached to them, the imagination of the student will be in danger of being chilled, and his taste will be liable to become depraved. To reduce art to such rule as canon implies is supererogatory, for it is impossible to name a single canon of the kind that might not have been improved by the abolition of the laws laid down for its formation. Canons in poetry, what *acrostics* and *bouts-rimés* are in poetry. Good poetry now disdains such laborious trifling in literature; let us hope that it will soon prove as influential in the sister-art.

CANON (in mathematics). This word, which signifies a rule, has generally been employed to mean a set of mathematical values. Thus it was customary to speak of the canon of logarithms, of sines, &c. A collection of formulae has sometimes been called by the same name, and even any mathematical instrument (*Latin*, *Lex Math.*)

CANON LAW, a

of ecclesiastical constitu-

tions for the regulation of the polity and discipline of the Church of Rome, consisting for the most part of ordinances of general and provincial councils, decrees promulgated by the popes with the sanction of the cardinals, and decretal epistles and bulls of the popes. The origin of the canon law is said to be coeval with the establishment of Christianity under the apostles and their immediate successors, who are supposed to have framed certain rules or canons for the government of the church. These are called the apostolical canons; and though the fact of their being the work of the apostles does not admit of proof, there is no doubt that they belong to a very early period of ecclesiastical history.

These rules were subsequently enlarged and explained by general councils of the church. The canons of the four councils of Nice, Constantinople, Ephesus, and Chalcedon (which were held at different times in the fourth and fifth centuries), received the sanction of the secular power by a law of the Emperor Justinian. (Novel. 131, cap. 1.) The chapter referred to, after confirming the decrees of the four councils, adds, 'we receive the doctrines of the aforesaid holy synods (i. e. councils) as the divine Scriptures, and their canons we observe as laws.' Collections of these canons were made at an early period. The most remarkable of these collections, and that which seems to have been most generally received, is the *Codex Canonum* which was compiled by Dionysius Exiguus, a Roman monk, A.D. 520. This body of constitutions, together with the capitularies of Charlemagne and the decrees of the popes from Siricius (A.D. 398) to Anastasius IV. (A.D. 1154), formed the principal part of the canon law until the twelfth century. The power of the popes was then rapidly advancing to the height which it afterwards attained, and their jurisdiction being constantly extended by new encroachments, required a uniform system of law for the regulation of their decisions.

This necessity excited the active zeal of the monkish lawyers. After some minor compilations had appeared, a collection of the decrees made by the popes and cardinals was begun by Ivo, bishop of Chartres, A.D. 1114, and perfected by Gratian, a Benedictine monk, in the year 1150, who first reduced these ecclesiastical constitutions into method. The work of Gratian is in three books, arranged and digested into titles and chapters in imitation of the *Pandects* of Justinian, and is entitled 'Concordia discordantium Canonum,' but is commonly known by the name of 'Decretum Gratiani.' It comprises a series of canons and other ecclesiastical constitutions from the time of Constantine the Great, at the beginning of the fourth, to that of Pope Alexander III., at the end of the twelfth century. The Decretals, which were rescripts or letters of the popes in answer to questions of ecclesiastical matters submitted to them by private persons, and which had the authority of laws, were first published A.D. 1234, in five books, by Raymond de Renafort, chaplain to Pope Gregory IX. This work, which consists almost entirely of rescripts issued by the later popes, especially Alexander III., Innocent III., Honorius III., and Gregory IX. himself, forms the most essential part of the canon law, the Decretum of Gratian being comparatively obsolete. These decretals comprise all the subjects which were in that age within the cognizance of the ecclesiastical courts; as the lives and conversation of the clergy, matrimony and divorces, inquisition of criminal matters, purgation, penance, excommunication, and the like. To these five books of Gregory, Boniface VIII. added a sixth (A.D. 1298), called 'Sextus Decretalium,' or the 'Sext,' which is itself divided into five books, and forms a supplement to the first five books, of which it follows the arrangement. The Sext consists of decisions promulgated after the pontificate of Gregory IX. The Clementines, or Constitutions of Clement V., were published by him in the council of Vienna (A.D. 1308), and were followed (A.D. 1317) by those of his successor, John XXII., called *Extravagantes Johannis*. To these have since been added some decrees of later popes, arranged in five books after the manner of the Sext, and called *Extravagantes Communes*. All these together, viz., Gratian's Decree, the Decretals of Gregory IX., the Sext, the Clementines, and the Extravagants of John XXII. and his successors, form what is called the *Corpus Juris Canonici*, or body of canon law. Besides these, the institutes of the canon law were compiled by one John Laticlout, by order of Paul IV., in the sixteenth century; but it appears from the author's preface that they were never publicly acknowledged by the popes.

And in 1661 was published a collection of the decretals, different councils, which is to be found in some editions of the Corpus Juris Canonici, but this likewise has never received the sanction of the Holy See.

The introduction of this new code into the European commonwealth gave rise to a new class of practitioners, commentators, and judges, almost as numerous as those who had devoted themselves to the study and exposition of the civil law, from which, as from an analogous system of jurisprudence, they looked for aid in all cases of difficulty and doubt. In fact, the two systems of law, though to a certain extent rivals, became so far mutually entwined, that the tribunals of the one were accustomed, wherever their own oracles were silent, to adopt the rules of decision that prevailed in those of the other.

The main object of the canon law was to establish, by means of the legislative authority of the pope, the supremacy of ecclesiastical authority over the temporal power, or at least to assert the total independence of the clergy upon the laity. The positions, that the laws of laymen cannot bind the church to its prejudice, that the constitutions of princes in relation to ecclesiastical matters are of no authority, that subjects owe no allegiance to an excommunicated lord, are among the most prominent doctrines of Gratian's Decretum and the decretals. We have shown in a former article [BENEFICE, vol. iv. p. 218] that the encroachments of the church upon temporal rights and authorities were never encouraged in England. The doctrines of passive obedience and non-resistance, so slavishly inculcated by the decretals, were not likely to be relished by the rude and fierce barons who composed the parliaments of Henry III. and Edward I. Accordingly we find that this system of jurisprudence never obtained a firm or extensive footing in this country: and our most eminent lawyers, in all periods of our history, have shown great unwillingness to defer to its authority. It is well observed by Blackstone (*Com. i. p. 80*) that "all the strength that either the papal or imperial laws have obtained in this realm is only because they have been admitted and received by immemorial usage and custom in some particular cases and some particular courts; and then they form a branch of the *leges non scriptæ*, or customary laws; or else, because they are in some other cases introduced by consent of parliament, and then they owe their validity to the *leges scriptæ*, or statute law." There was indeed a kind of national canon law, composed of *legatine* and *provincial* constitutions, adapted to the exigencies of the English Church. Of these the former were ecclesiastical laws enacted in national synods held under the cardinals Otho and Othobon, legates from Pope Gregory IX. and Clement IV. in the reign of Henry III. The provincial constitutions were the decrees of provincial synods held under divers archbishops of Canterbury, from Stephen Langton, in the reign of Henry III., to Henry Chichele, in the reign of Henry V., and adopted also by the province of York in the reign of Henry VI. (Blackstone, *Com. i. p. 83*; Burn's *Eccl. Law*, preface.)

With respect to these canons it was, at the time of the Reformation, provided by stat. 25 Henry VIII., c. 19 (afterwards repealed by 1 Philip and Mary, c. 8, but revived by 1 Eliz. c. 1), that they should be reviewed by the king and certain commissioners to be appointed under the act, but that, till such review should be made, all canons, constitutions, ordinances, and synodals provincial, being then already made and not repugnant to the law of the land or the king's prerogative, should still be used and executed. No such review took place in Henry's time; but the project for the reformation of the canons was revived under Edward VI., and a new code of ecclesiastical law was drawn up under a commission appointed by the crown under the stat. 3 and 4 Edward VI. c. 11, and received the name of *Reformatio Legum Ecclesiasticarum*. The confirmation of this was prevented by the premature death of the king, and although the project for a review of the old canons was renewed in the reign of Elizabeth, it was speedily dropped, and has not been since revived.

The result of this is, that so much of the English canons made previously to the stat. of Henry VIII. as are not repugnant to the common or statute-law, is still in force in this country. It has however been decided by the Court of King's Bench that the canons of the convocation of Canterbury, in 1603 (which, though confirmed by the king, never received the sanction of parliament) do not (except so far as they are declaratory of the ancient canon law) bind the

laity of these realms. (*M. [di]st. 2. Croft; Strange's Reports, 1056.*) It was however admitted by Lord Hardwicke, in the above-mentioned case, that the canons are confirmed by

There are two species of courts in England, in which the canon law is under certain restrictions used. 1. The courts of the archbishops and bishops and their derivative officers, usually called in our law Courts Christian, *Curia Christianitatis*, or ecclesiastical courts. 2. The courts of the two universities. In the first of these, the reception of the canon law is grounded entirely upon custom; but the custom in the case of the universities derives additional support from the acts of parliament which confirm the charters of those bodies. They are all subject to the superintendence and control of the courts of common law, which assume the exclusive right of expounding the laws relating to the ecclesiastical courts, and will prohibit them from going beyond the prescribed limits of their respective jurisdictions; and from all of them an appeal lies to the king in the last resort.

Before the Reformation, degrees were as frequent in the canon law as in the civil law. Many persons became graduates in both, or *juris utriusque doctores*; and this degree is still common in foreign universities. But Henry VIII., in the twenty-seventh year of his reign, issued a mandate to the university of Cambridge, to the effect that no lectures on canon law should be read, and no degrees whatever in that faculty conferred in the university for the future. It is probable that Oxford received a similar prohibition about the same time, as degrees in canon law have ever since been discontinued in England.

Before we conclude this article, it may be as well to observe that the Decree of Gratian and the Decretals are usually cited not according to book and title, but by reference to the first word of the canon, which renders it necessary for the modern reader to consult the alphabetical list of the canons, in order to find out the book, title, and chapter, under which the canon he wishes to consult is to be found.

CANO/PUS or CANO/BUS (*Κάνωβος*), a city of Egypt, on the coast near the outlet of the eastern or Canopic branch of the Nile. It was 120 stadia from Alexandria by land, with which it was connected by a canal. In the time of Strabo (p. 801) it contained a great temple of Serapis.

CANOPUS is also the name of an Egyptian jar of a big-bellied form, with a cover or top representing a human head or that of some animal. These vessels are generally made of baked earth, sometimes of alabaster, and even of green basalt. Some have hieroglyphics on them, and are painted and glazed. Bodies of sacred animals are sometimes found in these vessels. Canopus is the Greek form of the name of an Egyptian deity; but whether the deity was the same as Cneph or Cneph, as some assert, we cannot tell. Earthen jars of this form seem to have been used for keeping water cool, as they still are in Egypt.

CANO/PUS, a star of the first magnitude, in the rudder of the constellation Argo. In Ptolemy it is *κάνωβος* (*canobus*), in Pliny *canopus*. It does not become visible to any part of the earth higher in latitude than the southern part of the Mediterranean.

Hyginus, the author of a book of gossip about the stars, and Martianus Capella, a poet (cited by Grotius), have stated that Canopus was a star in the constellation Eridanus, which they say was the Nile, and the star was therefore the island of that name. Sir John Hill, a modern Hyginus, author of just such another work, has stated that "some old astronomers" have placed Canopus as above described; and Dr. Huxon, who should not have made an authority of Sir John Hill, has copied his words, and repeated the mistake in his Mathematical Dictionary. It therefore becomes worth while to correct it.

CANOPY, the covering over a niche used in Gothic architecture. These canopies afford an opportunity for the display of considerable taste and ingenuity; they are usually elaborately carved. Being intended not merely as a covering to protect the statues under them from the weather, but as a mark of distinction also, they were used like a baldachin. The various Gothic edifices in England present numerous examples of canopies, and they occur frequently on the tombs of our kings and princes, placed horizontally, and therefore in such a situation as clearly shows that they

are intended, like a baldachin, to be a mark of honour, and not a mere covering.

CANOVA, ANTONIO, was born November 1, 1757, at Possagno, a considerable village in the province of Treviso, in the Venetian terri.

The father of Canova worked in stone, and was also an architect of some merit, so that his son may be said to have been initiated from his very birth in the pursuit in which he became so distinguished. At fourteen years of age Canova was taken by his father to Venice, and having obtained the notice of Giovanni Faliero, a senator, he was through his recommendation received into the studio of one Bernardi, surnamed Torretti; and afterwards, on Torretti's death, into that of his nephew, Giovanni Ferrari. Two baskets of flowers carved in marble for Faliero are still shown at Venice as the earliest finished productions of Canova's hand. About this time he commenced his first work of imagination, a group of Orpheus and Eurydice, which he modelled at his native village, during the time that he used to walk to Venice to attend the academy. Having now acquired some reputation, and being recommended by his first kind protector Faliero, he was employed on some other works, chiefly busts; and he also modelled his group of Daedalus and Icarus—a work which may be said to have laid the foundation of his future fame. In the year 1779 the Cav. Zuliano was sent ambassador from Venice to Rome, and the senator Faliero, anxious to advance the studies of the young sculptor, gave him a recommendation to that functionary. In October of that year he arrived at Rome, accompanied by Fontana, a Flemish painter. His group of Daedalus and Icarus was sent to him, and the account of the impression which it made is interesting. Zuliano was one of the most distinguished patrons and admirers of the fine arts, and his palace was the rendezvous of all the best artists, critics, and literati of the day. The work of Canova being well placed in one of the saloons, a large party of connoisseurs, consisting of Cades, Volpato, Battoni, Gavin Hamilton (a painter), the Abbate Puccini, and others, were invited to dinner, and after the repast they were conducted into the room where were the artist and his group. The qualities of art which they were now called upon to judge, viz., simplicity, expression, and unaffected truth to nature, were so different from that which was the mode, and to which they had been accustomed, and which some of the party no doubt thought excellent, that for some time there was a profound silence. Gavin Hamilton at length relieved the youthful sculptor from his embarrassment, pronounced the highest encomiums upon his work, and gave him at the same time kind and valuable advice and encouragement. This liberality was not thrown away upon the amiable heart of Canova, who, through his long career of success, always acknowledged with gratitude the important service thus rendered him by Mr. Hamilton. Canova returned to Venice, but soon after established himself in Rome, having obtained a pension from his government of 300 ducats a year for three years. His first work after his settlement there was a group of Theseus and the Minotaur; an extraordinary production for the time, and showing a feeling for the purer principles of art, both in composition and the style of the naked, totally distinct from the wretched manner that characterised the performances of his contemporaries, and of those who had for some years preceded him. His admitted superiority of talent required but little aid from the influence of his noble protectors to procure him some important employment, and he was selected to execute the monument of Ganganelli (Pope Clement XIV.) for the church of the SS. Apostoli, in Rome. This noble work of art was exhibited in 1787, and established at once Canova's claim to the highest rank in his profession. There is a curious and interesting letter extant from Milizia, the Assistant of his day, as Cicognara calls him, to the Conte Sanguisetti on the first exhibition of this monument. It speaks in terms of most unbounded admiration of the work, saying that it may lead to the 'risorgimento'—the restoration of real art! Before this was completed Canova had commenced his model of Rezzonico's (Clement XIII.) monument. This work is in St. Peter's, and is a splendid effort of genius, and of skill in execution. The angel of death and the two lions at the base of this composition cannot be too highly praised. A story is told in Rome of Canova's patting on a monk's dress and cowl, and in this disguise mixing with the crowd, to hear the criticisms that were made when the work was first exposed to public view.

From Canova was constantly employed, and chiefly on subjects of imagination. His Cupid and Psyche, his fine group of Hercules building Lycas from the rock, Theseus with the Centaur, the Graces, Statues of Nymphs, Endymion, &c. &c., are so well known, if not in the originals at least by engravings, to require description here. In portrait Canova was considered less successful; though none who have seen his Popes Ganganelli, Rezzonico, and Braschi, will deny his power even in that branch of his art. It is fair to judge by the best works, and the highest authorities have pronounced the head of the last mentioned Pope, Pius VI., to be a masterpiece of the art. For the union of portrait with ideal (that is, elevated) form, we would instance the statues of Napoleon, and of Letizia, mother of Napoleon. From among the great number of monumental groups executed by Canova besides those of the popes already mentioned, that of Maria Christina, in the church of Santa Maria do' Frari at Vienna, is characterized by simplicity of composition, expression, and exquisite finish.

Canova travelled when young over part of Germany, and was twice in Paris. At his last visit, when sent there by the Roman government to superintend the removal of the works of art which had been taken to Paris by the French, and which the Allies had decided should be restored to Italy, he proceeded to England, chiefly for the purpose of seeing the Elgin marbles, of which he always spoke in terms of the highest admiration, saying that the sight of such exquisite works was sufficient to repay him for his journey from Rome. His reception in England gave him the greatest satisfaction, and he took every opportunity of expressing feelings of admiration and gratitude towards this country. On his return to Rome he received a patent of nobility, and was created Marquis of Ischia. As remarkable for his unpretending modesty as for his talent, Canova never assumed his high title, though he was of course addressed by it, but so the last called himself and left his cards as Antonio Canova.

In the latter part of his life Canova was busily occupied in modelling decorations, such as a group of a Deposition and some bassi rilievi for a church which he had built in his native place; and it was at Venice, where he was staying to be near this object of his interest, that he died in October, 1822, after an illness of a very few days.

Canova was rather below the common stature, and latterly stooped as he walked. His features were strongly marked, but of fine form; his nose aquiline, and his eyes deeply set and full of expression. The general character of his countenance was extremely pleasing and prepossessing, a smile usually playing about his lips, indicative of the good-nature and kindness of disposition for which he was eminently distinguished.

Of most amiable and conciliating manners towards his brother-artists and competitors for fame, he was also the liberal supporter and encourager of students of rising talent. He gave pensions to several whose means were insufficient without such assistance, and established out of his own purse a handsome premium for sculpture in the academy of St. Luke, at Rome, of which he was 'Principe,' or perpetual president.

In execution, and the whole treatment of his marble, Canova was unrivalled; but those who are competent to judge sculpture by the pure principles of Greek art (or, in other words, of nature, selected and exhibited in its finest and most approved forms), will perhaps discover in many of his works some affectation, both in the attitudes and expression, and a littleness in some of the details, which are not in accordance with the simplicity and breadth of style of the best productions of the ancients. Admitting this to be the case (particularly in some of his latter performances), and that the criticism is therefore just, still his works evince so great a progress in art, and in many respects approach so much more nearly than those that had for a long period preceded them, to the excellence of ancient sculpture, that Canova must be confessed to be one of the great regenerators of the art; and his name, to which we may fairly add that of our countryman Flaxman, as the restorer of a pure style of design, will ever be held in honour by those who wish to see sculpture practised upon true principles.

For further particulars of Canova's life and works, see chiefly Cicognara, *Storia della Scultura*, tom. iii.; and Misirini, *Vita di Canova*, 8vo.

CANTABRI, a people of ancient Spain, who lived E. of the Asturias, in the region now called Las Montañas de Santander. To the E. they bordered on the Autrigones.

and the Varduli, or scayans. To the S. the seem to have extended beyond the mountains into part of the present province of Palencia, where they descended on the Vaccaei (Mannert, *Geographie der Griechen und Römer*.) They were a brave, secluded, half wild race, who long resisted the Romans, and were only finally subdued, together with the Asturians, by Augustus, B.C. 25. They revolted again, after some years, but were defeated and nearly exterminated by Agrippa B.C. 19. In the division of Spain made by that emperor the Cantabri were included in the *Tageconensis* province. They gave their name to the Oceanus Cantabricus, now Gulf of Biscay.

CANTACUZENUS, JOANNES, emperor of Constantinople. [BYZANTINE HISTORIANS.]

CANTAL, a department of France, the most southern of the two into which the former province of Auvergne has been divided. It is of a very irregular form, having its greatest dimension, or length from N.E. (near Massiac) to S.W. (near Maurs) sixty-seven miles; and its greatest breadth at right angles to the above about fifty-six miles. The surface comprehended in it is, according to M. Balbi, equal to 2090 square miles, being rather larger than the English county of Norfolk. It is bounded on the N. by the department of Puy de Dôme, on the N.W. by that of Corrèze, on the S.W. by that of Lot, on the S. by that of Aveyron, on the S.E. by that of Lozère, and on the E. by that of Haute Loire (Upper Loire). Aurillac, the chief town, is 270 miles nearly due S. from Paris in a straight line; or 332 by the road through Orleans, Limoges, and Tulle. The population in 1832 was 258,594, or nearly 124 to a square mile.

Cantal is one of the most mountainous departments in France. The mountain from which the department takes its name, Le Cantal, is near the centre of the department, and approaches in figure to a depressed irregular cone. In common with most of the other mountains of Auvergne it is of volcanic origin; and the lava, probably in consequence of its superior fluidity to that ejected from Mont Dor, has spread to a considerable extent without accumulating into such enormous masses as those which distinguish the neighbourhood of the latter. The valleys which furrow the sides of Le Cantal are less numerous, or at least narrower than those of Mont Dor: they stretch out on every side like rays from the central heights into the surrounding country; they are generally deep, and bounded by steep and rocky walls, and exhibit on each side corresponding sections of the volcanic beds through which their excavation has been effected, and towards their termination cut into the base of the primitive rocks by which the beds of lava are supported. The elevation of Le Plomb de Cantal, the summit of the mountain, above the level of the sea, is 6090 or 6094 feet. Several streams rise on the slope of this central mountain mass: the Sautoire, the Rue, the Mans, and several others, rise on the northern side, but flow N.W. into the Dordogne; the same river also receives the streams of the Marone, the Cère, and others, which rise on the western slope: the streams which rise on the S. side flow into the Truerye, while the Alagnon which rises on the eastern side flows into the Allier. The Celle rises in the south-western part of the department, and flows into the Lot; and the Truerye which rises in the adjoining department of Lozère, and falls into the Lot, waters the S.E. part, receiving in its course many tributaries. The Bés, a tributary of the Truerye, skirts part of the south-eastern boundary of the department; the Dordogne, a part of the north-western. The road from Paris to Narbonne, Perpignan, and the E. of Spain, crosses the eastern side of the department, running through St. Flour: this is a *route royale* (government road) of the first class; a *route royale* of the third class crosses the western side of the department through Mauriac and Aurillac; another road of the same class runs from Aurillac through Murat to St. Flour; and two others run from Aurillac, one N.W. to Argentat (Corrèze), the other S.W. to Figeac, Villefranche, and Toulouse.

For the geology of this mountain mass, we refer to the article *Auvergne*, geology of.

The agricultural and manufacturing industry of the department is thus described in the last edition of Malte Brun's *Géographie Universelle*. "In the elevated valleys, on the most lofty crests, and even to the summit of the Plomb de Cantal, the most important mountain of this groupe, of which it occupies the central point, the pastures and meadows are covered with cattle; their extensive pas-

ture affords nourishment even to those of the neighbouring departments. The oxen fattened in the department are sent to every part of France. The sheep are sent to the southern departments; the goat skins and kid skins, which constitute articles of trade between this department and that of Aveyron, are sent to Millau, where they are made into parchment; the horses, small in size, but strong, are used for the light cavalry. It is in the *burons*, huts scattered among the pasture lands, that the milk of the flocks is made into butter and into cheese of three different qualities. The farmer grows rye and buck-wheat, the chief articles of his food; flax, which in fineness rivals that of Flanders; hemp, which is woven into coarse cloth, used in our navy, or sold to the Spaniards; potatoes; fruit-trees of various kinds, especially chestnut-trees, the fruit of which is much used for food; and lastly, some vines which yield only sparkling wine. The manufactory of kettles, and various culinary utensils in copper, and the manufacture of lace, make up nearly the whole industry of the department: no mines are worked, with the exception of some coal-pits; but a great number of the inhabitants every year travel into other parts of France, into Spain, and even into Holland, to follow their trade as braziers. In the southern part of the department on the right bank of the Rance, the 1500 inhabitants of Maurs (population more exactly 1668 for the town, 2892 for the whole commune), raise many hogs, and carry on a large trade in hams."

This department is divided into four *arrondissements*: Aurillac on the S. and S.W. (population 95,284); Mauriac on the N.W. (population 63,003); Murat on the N.E. (population 35,364); and St. Flour on the E. and S.E. (population 64,943). Two towns only are of sufficient importance to require notice in a separate article: Aurillac, the capital, on the Jourdanne, a feeder of the Cère (population 8704 for the town, and 9766 for the commune); and St. Flour, an episcopal city on the Lende, a feeder of the Truerye (population 5813 for the town, 6464 for the whole commune). [AURILLAC; FLOUR, ST.] Of the others we shall give some account here.

Mauriac, the chief place of one of the *arrondissements*, is on the side of a basaltic hill which rises between the rivers Auze or Ouze and the Dordogne. One edifice, built a few years since, serves at once the purpose of the town-hall, and of the office of the sub-prefect. Mauriac has a public walk, commanding an extensive view, and the environs of the town are in several parts distinguished for their picturesque scenery. The elevated situation of this town causes the atmosphere to be very cold. The inhabitants amount to 2395 for the town, or 3530 for the whole commune. They carry on trade in cattle and horses.

Murat, also the chief place of an *arrondissement*, is on the bank of the river Alagnon near its source, and on the road between Aurillac and St. Flour. The inhabitants are engaged in manufactures; the men in that of coarse woollen cloth, the women in that of lace. The population amounts to 2563 for the town, and 2941 for the whole commune: they carry on a trade in cheese.

Vic en Carladéz, near Aurillac, is on the bank of the Cère. It has a population of about 2500: the females are remarkable for their blooming complexion and graceful carriage. There are some mineral waters in this town, which are well frequented; they are cold in their temperature, and diuretic in their operation.

Chaudes Aigues, near the Truerye, was known to the Romans under the name of *Calentes Aquæ*. The baths there are called by Sidonius Apollinaris, in allusion to the baths of Baia near Naples, *Calentes Baia*. The ordinary population of this town is about 2000; but in the bathing season it is doubled. The waters rise to the temperature of 80° of Reaumur, or 212° of Fahrenheit, according to the more moderate statement in the table given in Malte Brun's *Géographie Universelle*, they vary from 20° to 65° of Reaumur, or 68° to 149° of Fahrenheit. The waters are of a healthy character. They are made to answer all the domestic purposes of warm water; and being distributed by underground channels, serve to warm the apartments on the ground-floor of the houses in winter. Some lace is made in this place.

Carlat, near Aurillac, is remarkable for the ruins of an old castle on the crest of a basaltic rock, formerly the principal fortress of Auvergne. The population of Carlat is about 1000.

Salers, between Mauriac and Murat, is built on a bed

of volcanic matter, and gives name to the surrounding mountains, on which the finest cattle in Auvergne are reared: the mountaineers have the character of independence and quarrelsomeness. Some woven coarse ligens are made at *Salers*, and at *Pleaux*, (population of town 1634, of whole commune 3123,) near *Mauriac*; and some leather is tanned at *Allanches*, near *Murat*.

The department of Cantal sends three members to the Chamber of Deputies. It constitutes the bishopric of St. Flour; and is under the jurisdiction of the *Cour Royale* of Riom. It is in the nineteenth military division, of which Lyon is the capital.

CANTATA, in music (from *cantare*, It. to sing), originally signified a short lyric drama, consisting of recitative, airs, duets, and occasionally choruses, the subject of which was sometimes sacred, but more commonly of the erotic kind. The invention of the cantata is generally ascribed to *Giacopo Carissimi*, pontifical Maestro di Cappella, about the year 1650. Subsequently it assumed a more contracted form, and was written for a single voice. Of the latter kind the most celebrated are those of *Alessandro Scarlatti*, *Handel*, *Porpora*, *Marcello*, *Pergolesi*, &c. Purcell's 'Mad Bess' and 'From Rosie Bowers' are cantatas that far exceed in depth of feeling and richness of harmony any that either preceded or followed them. Dr. Pepusch's 'Alexis,' a lighter composition, is a justly-admired cantata; and Dr. Arne's 'Cymon and Iphigenia,' for simplicity and sweetness of melody, is entitled to our notice.

CANTEEN, a small wooden vessel capable of containing three pints, which is carried by each soldier on the march on foreign service or in the field. The use of them has been some time general in the British army; they are usually made of oak and painted blue. They are slung over the shoulder by a leather strap, and have the number or appellation of the battalion and regiment, and the number or letter of the company to which they belong painted on one end.

Another kind of canteen is a square box fitted up with compartments, in which officers on foreign service pack a variety of articles, such as spirit-bottles, tea and sugar canisters, plates, dishes, knives, forks, glasses, and other requisites for the table.

A canteen is also a place in barracks where a licensed sutler is allowed to sell provisions, liquors, coffee, &c. to non-commissioned officers and privates, and the quartermaster of the regiment is responsible that no irregularity occurs; the sale of wine, beer, or spirits is not allowed except at the canteen, and the quantity sold at one time is regulated by the commanding officer.

CANTEMIR, DEMETRIUS, was born in 1673 of a family originally from Little Tartary. His father was governor of Moldavia, and Demetrius obtained of the Porte the same office in 1710. But differences arose between him and the grand vizier, in consequence of which Cantemir entered into negotiations with Peter the Great, and revolted against the Porte. After Peter's retreat in 1711 he was obliged to quit Moldavia and to accompany the Russian army. Peter gave him in compensation lands in the Ukraine, and created him a prince of the Russian empire. Cantemir died on his estate in the Ukraine in 1723. He left several works: 'History of the Origin and of the Decay of the Ottoman Empire,' written originally in Latin, and translated both into French and English; 'On the State of Moldavia,' with a map of the country; 'History of Moldavia, Ancient and Modern,' in the Moldavian language; 'Introduction to the Music of the Turks'; 'System of the Mohammedan Religion,' written in the Russian language, and dedicated to Peter the Great. Cantemir was acquainted with many languages; he was also member of the Academy of Berlin. His son Antiochus was Russian ambassador at Paris, where he died young in 1744. He wrote several works in Russian; his 'Satires' were translated into French by Abbé Guasco.

CANTERBURY, a city of Kent, and the metropolitan see of all England, stands on the river Stour, on the high road from London to Dover, in 51° 17' N. lat., 1° 15' E., from Greenwich observatory. On the W. it joins the hundred of Westgate, on the N. the jurisdiction of Fordwich, and, towards the S. and E., the hundred of Bridge and Petham. At the time of the Roman occupation it was of considerable importance, as is evident from the Roman military roads to Dover and Lympne, their two principal havens. The ancient British name seems to have been *Durwhorn*,

in Kent, into *Durovernum*, signifying a place where the Saxons were probably given to it from the circumference of the city with some rapidity. Saxons it was called *Caer-Cant*, or the city of Kent; and we have *Cantuarie*, and *Cantuar*. There is no historical evidence to show what was its condition under the Britons or Romans, but there is no doubt that it was a place of importance; for at the beginning of the Saxon Heptarchy it was considered the chief city of the kingdom of Kent, and was the king's residence. Canterbury is pleasantly situated between hills of a moderate height, the air is salubrious, and the neighbouring country fertile. The city extends about half a mile from E. to W., and somewhat more from N. to S.; the circuit is about a mile and three quarters, and there are four suburbs at the four cardinal points. Many Roman coins, and Roman and Celtic remains, have been discovered in the city and neighbourhood.

Canterbury, in early times, suffered repeated ravages, and particularly from the Danes in 1011, when a great part of it was reduced to ashes. It has likewise frequently suffered by fire, the most calamitous instances of which were in the reigns of Henry II. and Henry VIII.; but it always recovered from these disasters, owing to its rank as the metropolitan city; and the constant resort of pilgrims tended in no small degree to enrich it. At Canterbury was founded the first regular Christian establishment of Augustine, who, in the year 597, baptized Ethelbert, king of Kent, and 10,000 Saxons in the river Swale. Augustine was the first archbishop, and died here in the year 604. His body was first buried in the monastery of St. Augustine, and afterwards, in 1091, was removed into the cathedral. Among the most celebrated of the archbishops are Thomas à Becket, who was murdered before the altar by four of the attendants of King Henry II. in 1171, and Thomas Cranmer, who was burnt at Oxford in the reign of Queen Mary. The cathedral, one of the most noble buildings in England, is of very ancient date; indeed, it disputes priority of origin (a matter which it would be difficult to settle) with the church of St. Martin, near Canterbury, which is generally admitted to be the oldest Christian church in England. Augustine is supposed to have commenced his cathedral on the site of a church which was built, during the Roman dominion in Britain, for the use of the Christian soldiers. The various parts of this cathedral having been built in different ages, its architectural character is of course various; but notwithstanding this, all the parts are so disposed as to produce a pleasing effect. The south side is most strongly marked by this diversity of style. The eastern end, called Becket's Crown, from having been finished during his tenure of the archbishopric, is circular; and the northern bears some resemblance to the southern. The south porch is a handsome unbattled structure, with a roof of stone. The great tower considered to be one of the most chaste and beautiful specimens of the pointed style of architecture in England. There are many windows of painted glass, of which the great western is the most remarkable. The stone screen behind the choir, and that behind the altar, lately erected, are much admired. The cathedral contains many monuments of regal and other personages. The choir is one of the most spacious in the kingdom, being nearly 200 feet in length, from the west door to the altar, and thirty-eight in breadth between the two side doors. The extreme length of the whole building, from east to west, is 514 feet, and the extreme breadth seventy-one feet. The height of the great tower is 35 feet. The cathedral has of late years undergone, and is undergoing, great repairs and judicious restoration, at the expense of the dean and chapter. One of the two towers at the west end is now (1836) in course of being rebuilt with stone from Caen in Normandy, of which the whole cathedral is constructed, except those pillars which are of Purbeck stone. The present establishment consists of a dean, twelve prebendaries, six preachers, six minor canons, and the usual officers. The grammar school, which is within the precincts, and is supported by the chapter, is called the King's School, having been re-modelled by Henry VIII. This school was originally founded by Theodore, archbishop of Canterbury, who died about 690. Among the ruins of ancient buildings may be traced the walls of a castle, said to have been built by William the Conqueror, which is on the S.W. side of the city, near the entrance from Ashford. These remains appear to have been the keep, or donjon, of a fortress, within which stood,

and of which the bounds may still be traced, like those of the castles at Dover, Rochester, and the White Tower in London: the building, being much in the same style with those just mentioned, may be about the same age. The ruins of the palace, which was originally built by Archbishop Lanfranc, are adjoining the borough of Staplegate, a suburb of the city. The ruins of St. Augustine's Monastery, so called either as having been built by or dedicated to him, are in the eastern suburbs: this abbey and its precincts occupied sixteen acres of ground, which were inclosed by a wall. The fine gateway of St. Augustine, which formed the chief entrance, was in a dilapidated state, but has been repaired within these few years by public subscription. The Pilgrims' Passage, by Mercery Lane, on the N. side of the High Street is towards the cathedral. Canterbury contains fourteen parish churches, and several dissenting chapels. The charitable institutions, for education, for the maintenance and relief of the aged and infirm, and other purposes, are numerous. The city and county hospital, a valuable and well-conducted establishment, was completed in the year 1798, and was erected and is now supported by voluntary contributions. The undercroft of the cathedral was given to the Walloons by Queen Elizabeth in 1568; who introduced the art of silk-weaving, which was afterwards prosecuted to a very considerable extent. This manufacture is now extinct. Canterbury city has long been noted for its brawn, an article of delicacy, which is sent to all parts of the kingdom. The trade in wool is large, but the chief trade is in corn and hops, for the cultivation of which the soil of the neighbourhood is particularly favourable. There are many mills on the banks of the Stour, some of which do a great deal of business. Frequent attempts have been made to render the Stour navigable from the sea to the city for ships of 100 tons burthen, but the probable smallness of revenue has always prevented the undertaking. A railway, constructed within the last five or six years, from Whitstable to Canterbury, is in full work, and has rendered very considerable benefit to the trade of the town. The carriage of coals and heavy goods has been reduced one half. Of the public buildings, the guildhall, the fruit and vegetable market, the new corn and leep exchange, the butter and fish markets, the philosophical museum, and the assembly rooms, are the chief. At the S.E. corner of a field, close to the city wall, is a large artificial mound, or circular hill. In the year 1710 Mr. Ashmole, James Samuel, Esq., town clerk, and others, who had been for many improvements, converted this place into a city wall; the spires of the hill were also cut into three walks, so as to admit an easy ascent to its summit, and were connected with a terrace formed upon the top of it within the wall, extending in length upwards of 600 yards. Additional walks were also made in the field in which it is situate, called the Dane John or Donjon field, and a double row of limes was planted on the sides of the principal walk. The public-spirited conduct of this individual was commemorated by a pillar erected on the summit of the mound. Some springs of mineral waters were accidentally discovered in 1693 on premises now used as nursery ground, and have from that time to the present been highly esteemed for their medicinal properties. One is purely chalybeate, and the other contains a portion of sulphur in combination with the iron. During the severest seasons these waters never freeze.

The city of Canterbury was in ancient times part of the royal demesnes, and was under the government of an officer appointed by the crown, styled the prefect, portreeve, or provost, who had all the civil authority, and accounted yearly to the king for the several profits arising from the city. In the last year of King John two bailiffs appear to have been appointed for these purposes, and to have continued till the 18th of Henry III., when the citizens were empowered to choose bailiffs for themselves. This constitution of the city remained until the 26th of Henry VI., when a charter of further liberties and privileges was granted, and that form of municipal government established which existed until the operation of the Municipal Reform Act. By the charter of Henry, and a subsequent parliament the 31st of his reign, the governing body consisted of the Mayor, recorder, twelve aldermen, twenty-four common councillors, a sheriff, town clerk, and other subordinate officers. The charter was confirmed and enlarged by Edward I., and the city was divided into a county by the name of the county of

the city of Canterbury. There were subsequent charters, by Henry VII., Henry VIII., James I., Charles II., and George III. The city was divided into six wards, named from each one of the six principal gates, each ward being presided over by two aldermen. The style of the corporate body is that of the mayor and commonalty of the city of Canterbury. Under the new act it has six aldermen and eighteen councillors. Quarter sessions are held by the recorder; and capital offences are removed to the assizes at Maidstone. The city has sent two members to parliament since the 23rd of Edward I. The present parliamentary borough comprises, in addition to the city and its precincts, what is called the borough of Longport, and parts of some other parishes. The number of acres within the city jurisdiction is 2780, rather more than 1470 have been added to the parliamentary borough. The division of the city, under the authority of the Municipal Act, is into three wards only, Westgate, Dane John, and North Gate. Canterbury has the advantage of a regular post, good markets, and excellent inns. There are two banking houses in high credit. The neighbourhood abounds in gentlemen's seats. From the situation of Canterbury on the main-road from London to the Continent the traffic is large, constant, and profitable. The distance from London by the road is 56 miles, from Sandwich 12, from Ashford 14, from Dover 16, and from Follistone and Deal 17. The markets are daily for provisions of all kinds, but the principal one, which is for cattle, corn, hops, and seeds, is holden on Saturday, and is sold free for corn. A market for fat stock is held every alternate Tuesday with Ashford. The annual fair, which commences on the 11th of October, and lasts from eight to ten days, is very numerously attended; being chiefly for poultry and toys. The population, according to the census of 1831, is 14,163.

(See: Batteley; Lambard; Hasted; Gostling; Camden; Municipal Corporation Reports.)

CANTERBURY BELLS, the vulgar name of an annual plant, often cultivated in gardens on account of its large blue or white flowers. It is a native of the mountains in the south and east of Europe, is the *Campanula Medium* of botanists, and is supposed to have been the *Medon* of the Greeks.

CANTHARIDE, a family of coleopterous insects of the section *Trachelodes*. Technical characters:—Hooks of all the tarsi cleft; antennae generally filiform; head usually broader than the thorax, and divided posteriorly by an indentation, thorax for the most part narrower behind than before; elytra soft and flexible, and in most of the species crossing the sides of the abdomen. The genus *Cantharis* may be distinguished from other genera of this family by the following characters:—Antennae long and filiform, the second joint very short; maxillary palpi short, the joints nearly equal, the terminal joint slightly exceeding the others in length; head a little wider than the thorax, which is slightly elongated, and has the anterior part suddenly narrowed, forming, as it were, a neck; elytra elongate, and somewhat linear.

Cantharis vesicatoria, the *Spanish fly*, or *blister-beetle*, is well known for its medical uses. It is about three quarters of an inch in length, and of a bright green colour; the legs and antennae are bluish black.

This insect is found but rarely in this country. It appears in the month of June, and frequents ash trees, upon the leaves of which it feeds. *C. vesicatoria* is also found in France, but in Italy and Spain it appears to be most abundant.

When touched these insects feign death, and emit an odour of a highly penetrating nature. Their larvae live in the ground, and feed upon the roots of plants.

CANTHARIS OFFICINALIS (Geoffroy); *Meloe vesicatorius* (Linnæus); *Lytta vesicatoria* (Fabr.); is extensively employed to produce blisters. The volatile principle which is exhaled by the living insect is so pungent as to cause great inconvenience to those who approach the trees where they alight. They are generally collected during the morning or evening when somewhat torpid, by persons, whose face and hands are protected by coverings, shaking or beating with poles the trees on which the insects are seated. The most common method of killing them is to expose them to the vapour of hot vinegar: they are then dried on hurdles, and put up for use. Turpentine is said to protect them from the attacks of certain small insects which prey upon particular parts of the dead insects.

14° 30' E. long., and is built on the Chookeang, a river which flows from the mountains N. and W. of the city. From the entrance of the river (called after the Portuguese *Bocca Tigris*) to Canton the distance is 32 miles; a ship sails a few points W. of N. until she arrives near the 'first bar,' and thence her course is nearly due W. to the anchorage at Whampoa, which is 10 miles below the foreign factories; the intercourse with which is entirely conducted in boats. On reaching the city the country to the N. and E. appears hilly and mountainous. The rivers and creeks, which are very numerous, abound with fish, and are covered with a great variety of boats, which are continually passing between the neighbouring towns and villages. S. of the city the country consists of an alluvial flat, being the delta formed by the depositions from the waters of the main river, with here and there a solitary hill of granite or red sandstone rising up like an island. Rice-fields and gardens, in a high state of cultivation, occupy the low lands, and trees, principally figs, cover the elevated points. That part of the city situated within the wall is built in the form of an irregular square, and divided by another wall, which runs from E. to W., into two parts. The N. and largest portion is called the old city; the S. part is called the new city. The whole circuit of the two together has been perambulated with ease in two hours, and may therefore be about six or seven miles. To the S. the wall runs parallel to the river at the distance of fifteen or twenty rods; on the N., where the city is built partly up the acclivity of the hills in the rear, the wall takes an irregular course, and it may be as much as 300 feet above the surface of the river.

The walls are composed of brick, with a foundation of coarse red sandstone, and vary in height from 20 to 30 feet. The gates of the city are 16 in all, but four of them lead through the wall which separates the old from the new city, so that there are only 12 outer gates, each distinguished by a name descriptive of its position. The suburbs resemble, in respect to their streets and buildings, the city within the wall, which is prohibited to and has seldom been entered by Europeans. Most of the streets are short, and irregularly laid out, varying in width from 10 to 15 feet.

The general appearance of the city is that of a passage of two centuries. The streets are narrow, and the houses are small, and the buildings are of a low height. The city is less regularly laid out than the suburbs, and the streets are more irregular. The city is more densely populated than the suburbs, and the streets are more narrow. The city is more ancient than the suburbs, and the streets are more old-fashioned. The city is more important than the suburbs, and the streets are more busy. The city is more interesting than the suburbs, and the streets are more varied. The city is more beautiful than the suburbs, and the streets are more pleasant. The city is more useful than the suburbs, and the streets are more convenient. The city is more healthy than the suburbs, and the streets are more clean. The city is more happy than the suburbs, and the streets are more cheerful. The city is more prosperous than the suburbs, and the streets are more thriving. The city is more powerful than the suburbs, and the streets are more energetic. The city is more wise than the suburbs, and the streets are more prudent. The city is more brave than the suburbs, and the streets are more courageous. The city is more honest than the suburbs, and the streets are more upright. The city is more just than the suburbs, and the streets are more equitable. The city is more merciful than the suburbs, and the streets are more compassionate. The city is more generous than the suburbs, and the streets are more liberal. The city is more kind than the suburbs, and the streets are more friendly. The city is more gentle than the suburbs, and the streets are more peaceful. The city is more quiet than the suburbs, and the streets are more calm. The city is more sober than the suburbs, and the streets are more modest. The city is more serious than the suburbs, and the streets are more dignified. The city is more respectful than the suburbs, and the streets are more courteous. The city is more considerate than the suburbs, and the streets are more thoughtful. The city is more helpful than the suburbs, and the streets are more useful. The city is more kind than the suburbs, and the streets are more friendly. The city is more gentle than the suburbs, and the streets are more peaceful. The city is more quiet than the suburbs, and the streets are more calm. The city is more sober than the suburbs, and the streets are more modest. The city is more serious than the suburbs, and the streets are more dignified. The city is more respectful than the suburbs, and the streets are more courteous. The city is more considerate than the suburbs, and the streets are more thoughtful. The city is more helpful than the suburbs, and the streets are more useful.

Near and upon the river the houses are built on piles, which render the foundations sufficiently secure. Bricks are generally used for the walls of houses; the only few of the poorer sort are constructed of mud. Stone and wood are sparingly used in building the first class of about gateway, and the second for columns, beams, and rafters. The roofing consists invariably of bamboo, which are laid on as alternately concave and convex, the latter overlapping the joined edges of the former and covered over them with mortar. Windows are small and are supplied with glass, paper, mica, or the interior lamina of oyster shells, as used in its place. Hardly any iron, a comparatively expensive substance, is employed about buildings. The materials for building are procurable at moderate prices and in abundance. The wood, a variety of fir, is floated down the river in huge rafts, bricks are made in the neighbourhood of Canton, and brought thither in boats, being sold from four to eight dollars a thousand.

The poorest persons live in the extreme parts of the suburbs, along the banks of the river and its creeks, and in the N. part of the old city; their houses are mere mud-hovels, low, narrow, dark, and without any division of apartments. In contrast to a little more numerous and cleanly than these about one-half of the population of Canton have their abodes. They stand close on the street, and have usually but a single entrance, which is closed by a bamboo screen suspended from the top of the door; within these houses there are no superfluous apartments; a single room allotted to each branch of the family serves as a dormitory, while a third, which completes the number into which the whole inclosure is divided, is used by all the household as a common eating-room. Chinese houses of consequence

open towards the S., but in the poorer sort this point must of course be often disregarded. The dwellings inhabited by the more wealthy part of the community are surrounded by a wall 12 or 14 feet high, that fronts the street, and completely screens the buildings within. The prospect along the narrow streets lined with these bare walls is very cheerless. The outer inclosure is entered through a large folding door (with a small one on each side of it) into an open court, within which is a visitors' waiting-room, furnished with chairs and small tables by their side. Here the guest is met and conducted into the principal hall, a spacious apartment ornamented with carved work, varnished and gilded, and hung with scrolls covered with fine writing, or representations of birds, flowers, landscapes, &c. The remaining part of the inclosure is occupied by the domestic participants and a garden or yard.

The portion of Canton in which the European factories are situated, being a mere suburb, does not contain many of the larger or public buildings, but the arrangement and architecture of the streets and shops are precisely the same as within the wall of the city. The shops are commonly quite open towards the street, that is, those appropriated to Chinese customers; for the few streets devoted to European trade are rather on a different plan, the shops being of a closer structure and less exposed to external observation. The several streets are commonly devoted to distinct trades. There is *Carpenter Street*, or rather Square, as it is called round a parallelogram; *Curiosity Street* (as the English call it) is devoted to the sale of antiques, real and fictitious; and *Apothecary Street* is full of druggists' shops, the drawers in which are neatly arranged and lettered, but filled principally with simples. By the side of each shop is suspended from on high a huge ornamental tablet of wood, varnished and gilded, on which are inscribed the particular calling of the tenant and the goods in which he deals. Either the police must be very good or the populace tolerably abstemious; for some of the shops, which are pretty richly supplied, appear to be much exposed towards the street; but the inhabitants of each division generally combine into a system of watch and ward for common protection, and during the night the streets are closed at each end by doors, when are guarded by the regular police. The greatest risk to which the houses and shops of Canton are exposed is that of fires, which in frequent instances are not the result of mere accident. The Chinese have very generally adopted the use of our engines, which they themselves manufacture sufficiently well to answer the purpose. The foolish notion of fatalism which prevails among the people makes them singularly careless as regards fire, and the frequent recurrence of accidents has no effect upon them, although the conflagration in 1822 went far to destroy the whole city. Vagabonds and beggars are very numerous in Canton. There is no levy of rates for the poor, but there are some small charitable institutions, which are few in number and small in extent. The amount of the native population of this city has been often estimated, but so little authentic information has ever been obtained on the subject, that it still remains a question wholly undecided. The population by which some have endeavoured to make it amount to a million does not seem to deserve much credit. As the circuit of the city does not exceed six or seven miles, and as the houses are not more than a single story in height, it seems difficult to imagine how such a number as a million can be contained within its precincts.

Under all the circumstances the climate is remarkably healthy, though extremely hot during the summer, and at all times subject to great and sudden vicissitudes. In July and August the thermometer sometimes reaches 100° of Fahrenheit in the shade, and during winter it occasionally falls below the freezing point at night; the average of the year is about 72°. No considerable part of the population lives upon the river, in the junks, barges, and small boats, a very large majority of the latter are called 'egg-house' boats, from their shape resembling the longitudinal section of an egg. They are generally not more than 10 or 12 feet long, about 6 broad, and so low that a person can scarcely stand up in them. Their covering consists of a bamboo or mat tilt, shaped like that of a waggon, which is very light, and serves tolerably as a defence against the weather. Whole families live in these boats, and are considered as a distinct part of the population, being under a separate regulation and not allowed to intermarry with those on shore.

It may perhaps seem incredible that the whole frontage of the buildings in which foreigners of all nations are shut up together for the prosecution of their trading business at Canton does not exceed between seven and eight hundred feet. Each front, of which there are about thirteen, extends backwards a hundred and thirty yards into a long narrow lane, on each side of which, as well as over arches that cross it, are the confined abodes of the English, French, Dutch, Americans, Parsees, and others. Many years back a considerable number of flags, as the Danish, Swedish, and Austrian, were hoisted in front of the factories, besides the English, Dutch, and American; but for the last quarter of a century these three, with the French tri-colour, which was erected soon after the revolution of 1830, have been the only foreign ensigns seen there. At present neither the English nor American flags are hoisted.

The European factories are called by the Chinese 'the thirteen Hongs,' the word hong being always used by them to denote a commercial establishment or warehouse; according to their custom, each factory is distinguished either by some appellation denoting wealth and prosperity, or by the name of its flag. Thus the Austrian factory was called the 'twin Eagle Hong,' a name which it retains to this day; the Danish, the 'yellow flag Hong'; the Company's, 'the Hong that ensures tranquility'; the American, 'the Hong of extensive domains'; and so on. To the east of all there is a narrow inlet from the river, a fetid ditch, which serves to surround a portion of the city wall, as well as to drain that portion of the town. This is crossed with a single arch by a narrow street at the back of the factories, that leads to the warehouses of the several Hong merchants, all of them communicating with the river by wooden stairs, from which the tea and other goods are shipped. The space occupied by the foreign factories is crossed by two well-known thoroughfares, one of them named China Street, and the other Hog Lane; to which a third, called New China Street, has been lately added. The first is rather broader than the generality of Chinese streets, and contains the shops of the small dealers in carved and lacerated ware, silks, and other articles in common demand by strangers. The shops, instead of being set out with the showy and sometimes expensive front of an English or French shop, are closed in by gloomy black shutters, and very ill lit by a small sky light, or rather a hole in the roof. The alley called Hog Lane is more narrow and filthy than any thing of the kind in a European town. The hovels by which it is lined are occupied by abandoned Chinese, who supply the poor ignorant sailors with spirit, mediated to their taste with stimulating or stupefying drugs; and when the wretched men have been rendered nearly insensible by these poisonous liquors, they are frequently set upon by their wily seducers, and robbed as well as beaten. It was here that the affrays, which many years ago so frequently led to homicides and consequent discussions with the government, in general originated, until the Company's authorities invested the senior commander of the fleet with the complete regulation and control of all boats, with their crews, at Canton. Powerful influence was at the same time used to put down the spirit-shops, or bind their owners by heavy penalties to good behaviour.

As Canton derives its chief interest and importance from being the sole emporium of the British trade with China, it becomes necessary to take some particular notice of this. The city and port to which it has been so long restricted (in fact ever since the present Tartar rulers possessed themselves of the empire) is nearly at the furthest possible distance from the capital. Two circumstances concur to render Canton the point most unsuited to promote the importation and consumption of British goods: these are, the comparative heat of the climate, and the difficulties of transport, arising not only from the distance, but from the upward navigation against two rapid streams from the west and north, and the crossing of high mountain ridges whence those streams derive their source. The policy of the Tartar dynasty in confining the European trade with such obstinacy to a point so unsuited to its extension may be explained on two grounds: first, the desire to remove the danger of external involvements from the vicinity of the capital; secondly, to derive the largest possible revenue from internal duties on transit, which in this instance are known to be large.

The direct annual revenue accruing from Canton to the emperor has amounted to about 1,200,000 taëls (nearly half a million sterling) on imports; but this bears no proportion

to the indirect gains accruing to Peking, or to the provincial government, from various contributions exacted from the Hong merchants under various names and pretexts. On a late occasion, it is well known that the expenses of quelling a rebellion in the north-west of the province were defrayed by the Hong merchants; the senior merchant having contributed 100,000 taëls. The Consol fund, presently to be explained, is a rich source of revenue to the Chinese, and a proportionately heavy burthen on our trade. The fiscal and custom-offices of Canton being nearly all of them farmed out, are also maintained by charges on the European commerce. As the Consol fund owed its origin to the peculiar constitution of that body of monopolists called Hong merchants, it may be as well to premise that this corporation and its privileges are founded as much in the peculiar policy of the government as in the cupidity of the individuals who have composed it. The pride and jealousy of the rulers of the country have kept them studiously aloof from a direct intercourse with foreigners, and they find it most convenient to throw the trouble and responsibility of managing Europeans on inferior delegates, and to practise their impositions through that intermediate channel. The Hongs consist at present of eleven individuals of very different degrees of wealth and character, some of the richest of whom have personally withdrawn from the trade since it was laid open to private shipping, but lend their capital to the active traders, without sharing their responsibility. The Hong merchants do not form a joint stock company, but are licensed to trade individually; although the whole body was, until the year 1830, liable for all the foreign debts of each member. It was then found that such a responsibility on the part of the body had given to the poorer members a degree of credit, and a facility in obtaining loans from Europeans, which had been the principal cause of the numerous bankruptcies, either real or fraudulent, among the indigent or improvident Hongs. In 1828 and 1829 two of them failed to the aggregate amount of about 2,000,000 dollars, but the whole was liquidated in the course of six years, and the last instalment paid at the commencement of 1834. The fund from whence such large sums have been drawn is derived from charges, amounting to about three per cent, laid by the Consol on foreign exports and imports, and it must therefore be a heavy burthen on the foreign trade. In stead of being allowed to terminate with the final payment of the European debts, there is every reason to be certain that these charges continue in full force, and serve to meet the vast demands made on the Consol by the government. Under these circumstances, there can be no room for surprise at the pertinacity with which the government supports a monopoly so profitable and convenient to itself, by the medium of which it can fatten at the expense of Europeans, without coming into direct collision with a race who are not disposed to accord those acts of deference and homage so grateful to its vain and despotic spirit.

The *Chung-hong*, 'true or imperial duties,' constitute the first item of Canton charges in order of payment, but are in fact only a small part of the whole. Notwithstanding the care with which both the government and the Hong merchants endeavour to conceal these mysteries from Europeans, a correct view of the above duties on imports has long since been obtained from the Custom-house books.

The second item is called *Kra-san*, 'add three,' being an addition of three in ten, or about thirty per cent. on all fixed duties. It is nominally a charge for changing dollar silver into sycee of the imperial standard, but greatly exceeds the real difference, and the surplus is supposed to be pocketed by the hoppers and his delegates.

A third item consists of a weighing charge on the pecul of 133 lbs., levied on all articles (even piece-goods) by weight, and forming a considerable addition to the regular duty.

The following is a summary view of the pilotage, port-charges, and other demands on European shipping entering Canton:—On nearing the coast from the southward, the Ladrões, two islands, called by the Chinese *Low-Mán-Shan*, are first made. A point lying S.E. of Macao, called Cabrita by the Portuguese, is then passed, and off it there is an exposed anchorage of four to three fathoms. Here ships send their boat ashore to Macao for a Chinese pilot, who is not often procured until the next morning; and when the weather is bad, ships run up at once to Lintin for shelter. The charts constructed from Ross's surveys

afford ample directions for piloting a ship to Whampoa, and the pilots are only fishermen employed by those who take out a government license to act. The pilot's fee inward is sixty dollars, and the same outward. On anchoring at Whampoa, nine or ten miles from Canton, two boats from the offices of the local authorities fasten on astern of each ship. A comprador or purveyor of provisions is generally hired, but a fee of fifty dollars is in any case paid, to meet the extortions of the Mandarins. A person called a linguist

is sent from each ship. Five or six of these men are by the government, and held responsible for the proceedings regarding the cargoes of European vessels.

Some time after reaching Whampoa, each ship is measured by the hoppo's officers, for the levying of the post-charge. What is called the *cumsha*, or present, is 1600 taëls on all vessels alike; but the measurement is charged at three different rates, according to the size of the ships, being calculated on the product arising from multiplying the length between the main and foremast by the breadth at the gangway.

	Dollars
The measurement on a ship of about 850 tons will be	2363
Present, on all ships alike	2223
Pilotage in and out	120
Small charges connected with pilotage	30
Linguist's fee	173
Compeador's fee	59
Total	4959

It is clear that these heavy imposts must hold out the strongest inducements to all ships, especially small ones, to evade them if possible; and to this circumstance, joined to the contraband nature of the opium trade, is to be ascribed the rapid growth of the smuggling depôt at Lintin, which commenced about the year 1822. As if to give an additional impulse to the increase of this smuggling station, the Chinese government, in 1825, in consequence of the scarcity of rice, enacted that ships bringing rice and no other goods, should be exempt from the measurement and *cumsha* charges at Whampoa. Ships now station themselves at Lintin, laden with rice, which they sell in sufficient quantities, to vessels newly arrived, to exempt them from the port charges; the foreign imports being either left at Lintin to be smuggled in, or put on board other ships which fill up entirely on freight for Whampoa. By gradual abuse, however, even rice ships have become subject at Whampoa to various irregular charges, amounting in all to about 900 dollars.

The Canton government begins to betray serious alarm at the increase of the smuggling system at Lintin, and this alarm is no doubt founded, first, in the evils arising from the lawless, independent, and violent habits which such a system engenders, and secondly, in the prospect of a decrease or annihilation of the revenue derived from the fair trade. A Chinese was shot on board a government boat at Lintin in 1827, another in 1831, and a village at Kumsing-moon (near Lintin) was attacked from the smuggling ships in 1832, on which occasion a Chinese was killed, but a Lascar at the same time was captured and put to death. As the vessels employed in the trade grow smaller and more numerous, these evils, unless remedied, may be expected to increase, until smuggling degenerates into piracy.

Some observations may here be introduced in regard to the prospect of opening a smuggling trade for British manufactures along the coasts of China E.N.E. of Canton. The late Dr. Morrison observed, as far back as 1823, 'The opening of any ports to the north for the resort of European ships is not a likely occurrence while the present rulers of China reign. They will not even allow tea to be carried coastwise to the south from the ports in Ch'keenng province, lest the traders should carry their cargoes to European ships or ports, and so deprive government of the revenue arising from the inland carriage; but most of all, lest a traitorous intercourse with Europeans should be opened, and the tea get to the possession of the English without passing through the Canton custom-house.' This is strictly true at present, and has been daily confirmed by the experience of the ves-

sels that have attempted to trade on the coast, where nothing succeeds as an import save opium.

In the experimental voyage of the *Amherst*, only a very small assortment of goods of various kinds was carried up, the object not being profit, but a mere trial. Even of this small quantity, the greater proportion was brought back to Canton unsold, though offered at any price, at a great number of places, during a voyage of six months. The conductors of the voyage admitted, in their report, that as a commercial speculation it must be considered to have failed, and the loss amounted to between five and six thousand pounds.

Experimental voyages were soon after made by individuals in imitation of the company. A vessel called the *Jamesina* sold some opium, and proceeded as far as Foo-chowfoo. The supercargo in vain sought to be allowed to trade; his views were frustrated by the vigilance of the government. He observed, on his return, 'My mind is made up, that until some important change in the relations of the two countries takes place, the only chance of pushing English manufactures on this coast is by leaving them a small item in an opium cargo.' The *Sylph*, another vessel, proceeded up to the Yellow Sea, and even touched on the coast of Tartary, but her endeavours to trade were generally fruitless.

A gentleman, sent by the government of Bengal to procure black and green tea plants from the neighbourhood of the provinces where they are cultivated, saw a great deal of the attempts to trade on the coast. He was of opinion that, without the consent of the Chinese government, any prospect of an advantageous or creditable intercourse did not exist.

Up to the 1st January, 1834, the number of British shipping entering Canton and Lintin (including the Company's trade), was upwards of 80 vessels annually, the aggregate burthen of which was about 60,000 tons. Of the whole value of the imports, opium constitutes at least one-half in amount; the remaining moiety consisting principally of raw cotton from India, and of woollens, cotton goods, and metals from England. Of the exports, tea has constituted nearly one-half the total value; the remainder consisting of raw silk and miscellaneous goods.

The following table exhibits a summary of the amount of British and Indian imports, in Spanish dollars, during the last five years of the Company's charter:—

East India Company		Private Account, including Officers of Company's Ships.		Total Value.
Cottons, Woollens, and Metals	Cotton Wool.	Opium.	Sundries.	
Dollars.	Dollars.	Dollars.	Dollars.	Dollars.
4,484,246	3,605,760	13,465,524	1,612,462	22,931,372
4,514,112	3,694,716	11,121,512	1,799,629	20,729,369
3,787,674	3,843,335	11,304,018	1,701,600	20,536,237
4,039,258	4,048,132	12,185,100	2,032,663	22,304,753
4,357,653	4,891,407	11,618	2,616,017	23,476,793

The value of exports from Canton in British ships, during the last five years of the Company's charter, is shown in the following table:—

Season.	East India Company.	Private Account, including Officers of Company's Ships.		Total Value.
	Tea.	Sundries		
	Dollars.	Dollars.	Dollars.	Dollars.
1829-30	7,848,104	706,092	12,704,061	21,257,257
1830-31	9,935,858	673,740	9,282,653	19,872,251
1831-32	9,214,238	757,625	7,795,623	17,767,486
1832-33	9,633,210	795,861	7,904,189	18,333,260
1833-34	8,039,163	1,044,586	11,309,521	20,442,250

Tea.—The bulk of the Company's exportations down to the end of 1833, comprised, under the head of black teas, bohea, congo, with soucheong and campoi, under which may be ranged the less considerable varieties of souchi and pekoe. The green teas consisted of the three principal distinctions of twankay, hyson skin, and hyson. The following is an abstract of the teas exported to England on account of the East India Company during the four last years of their charter, showing the different kinds:—

SEASON.	BLACK.						GREEN.					
	Bohea.		Congo.		Seachong and Campt.		Twankay.		Hyson Skin.		Hyson.	
	Chests.	Peculs.	Chests.	Peculs.	Chests.	Peculs.	Chests.	Peculs.	Chests.	Peculs.	Chests.	Peculs.
1830-31	66,691	39,347	216,380	136,700	4838	2848	54,711	32,856	2410	1184	20,762	10,271
1831-32	69,490	54,367	202,742	129,106	3572	2194	47,919	30,833	2415	1181	17,707	8860
1832-33	70,503	53,862	217,956	137,312	3867	2320	37,136	22,281	1593	786	13,282	6641
1833-34	84,835	62,487	171,571	109,176	5507	3370	48,190	29,781	1647	812	13,587	6739

As it is a question of importance how far a sudden increase in the demand for tea is calculated to injure its general quality, and to what extent factitious teas may be expected to be offered at Canton, the following information may be subjoined.

The remission of the tea duties in the United States occasioned, in the years 1832 and 1833, a demand for green teas at Canton which could not be supplied by the arrivals from the north-east. The Americans, however, were obliged to sail with cargoes of green tea within the season, and large prices were offered for the article. In consequence of some rumours which had reached him, an English gentleman prevailed on one of the Hong merchants with great difficulty to conduct him across the river to a place where they were manufacturing green teas from damaged black leaves. One of the tea inspectors attended, and they were witnesses to the following process.

In the first place, large quantities of black tea, which had been damaged in consequence of the floods of the previous autumn, were being dried in baskets with sieve-bottoms placed over pans of charcoal. The dried tea was then transferred, in quantities of a few pounds each, to a great number of cast-iron pans, imbedded in chunam over furnaces. At each pan stood a workman stirring the tea rapidly round with his hand (to prevent burning), with the addition of a very small quantity of finely powdered turmeric. This of course gave the tea a yellow tinge; but it was to be made green. For this purpose, some lumps of a fine dark blue were produced, together with a white powder, which, from the names given them by the workmen, as well as their appearance, were known to be Prussian blue and gypsum, or prussiate of iron and sulphate of lime. These two were triturated finely together with a pestle, to reduce the dark colour of the blue to a light shade, and a small tea-spoonful of the powder being added to a few pounds of the yellow leaves, they were stirred round as before until the tea had taken the fine bloom colour of Hyson, with a corresponding smell. To prevent all possibility of error, some samples of all the ingredients, together with the tea in its several stages, were carried away, and subsequently examined.

The tea thus coloured was banded in small quantities, on broad shallow baskets, to a number of women and children, who carefully picked out the stalks and coarse or ill-coloured leaves; and this being done it was passed in succession through sieves of different degrees of fineness. The first sifting produced what was sold as hyson skin, and the last as young hyson. As the party did not see the intermediate step between picking and sifting, there was reason to believe that the size of its leaves was first reduced by chopping or cutting with shears. If the tea has not highly deleterious effects, it can only be in consequence of the colouring matter existing in a very small proportion to the leaf. On attempting to enter several other houses where the same process was going on, the doors were suddenly closed upon the party.

This however was not the only effect of the suddenly increased demand for teas. The greater portion of the anko teas, under the denomination of caper, orange pekoe, and anko Congo, were in the second year mixed with spurious leaves. These were of several kinds, but appeared generally to be largish leaves cut up. The two most common were a thick, soft, dark green leaf, very smooth, and a palish baby leaf, with the veins strongly marked. The former is not detected easily, and only by inspecting the leaves after infusion, as it imparts no bad smell to the tea, and is hardly perceptible even to the taste: the latter is easily discovered by giving to the tea that smell and taste usually known in England by the terms 'faint and odd.'

American Trade, &c.—Next to the British trade the most considerable in tonnage and value has been that of the Americans; while the first however has progressed steadily to its actual amount, the latter has been subject to very great variations. The remission of the tea duties in America gave it in 1832-3 a sudden stimulus, and the exports and imports at Canton during that season each of them exceeded 8,000,000 dollars, on board of nearly 50 vessels. In consequence of the losses sustained on the teas the American tonnage in 1834 was greatly reduced, and will probably not very soon reach its previous amount.

Both the French and the Dutch trade with Canton seem to have a tendency to increase. There have lately been three or four French ships in port, where it was formerly unusual to see one; and in 1832, 17 Dutch vessels visited China from Holland or Java.

Money and Weights. There is at present no paper currency in China, although it was adopted by the Mongol conquerors of the empire, and subsequently abandoned in consequence of the depreciation and discredit which ensued from over issues and the bad faith of the government. The circumstances are stated very distinctly in the travels of the Arab, Ibn Batuta. 'When the paper was torn or worn out,' he observes, 'it was taken to the treasury, and supplied by new, marked with the government stamp. The profit arising from the circulation accrued to the sovereign.' 'They did not buy or sell with the dirhem or dinar, it is added, 'for should any one get these coins into his possession he would melt them down immediately.' This was the natural consequence of a depreciated paper currency. At Canton silver and a base alloy of copper are the two metals in circulation. The native copper coin is, from its low value, used only in bazaar payments, the exchange varying between 700 and 800 for a Spanish dollar. The Chinese seem to find it impossible to have a silver coin, from the propensity of the people to play tricks with any thing more valuable than their base copper money. The Spanish dollars imported into Canton are very soon punched into such a state as to be exchangeable only by weight. They even introduce bits of lead into the punch-holes, and none but freshly imported dollars are ever received without a very strict scrutiny, called shroffing. The charge attendant on this operation causes a premium in favour of new dollars to the extent of one or more per cent.

The broken Spanish dollars circulate by weight, and their proportion to the tale, or tael, varies in different transactions, being estimated, in the accounts among foreigners and native merchants, at the rate of 720 taels per 1000 dollars; but in the weighing of money, at 717 taels per 1000 dollars; and to 'outside dealers,' shopkeepers, and compradors, at 715 per 1000.

The Chinese money weights are as follows:—

Tale	Mace.	Candaren.	Cash.	Oz. Troy.	Gr. Troy.
1	10	100	1000	1.208	579.84
	1	10	100		57.98
		1	10		5.79

In the sycee, or fine silver, prescribed for the payment of government dues, 98 parts in 100 must be pure. This is cast in oblong ingots, of one and 10 taels in weight, with a stamp impressed. A large quantity has of late years, from the scarcity of dollars, been received at Lintin in exchange for opium. On being sent home to England it has been found on assay to contain a small quantity of gold, and has accordingly proved an advantageous remittance to London and Calcutta. It now bears a premium at Lintin of 44 per cent., and is procured with great difficulty at that. Gold is not used either as a medium of exchange or as an article of remittance. The present value of the finest is 20 dollars per tale weight.

The commercial weights are calculated in peculs, cutties and tals, and their proportions are according to this table :

Pecul.	Cutties.	Tals.	lbs. avoirdupois	Cwt.
1	100	1600	135½	1·19047
1	1	16	1½	

(A Description of the City of Canton; The Chinese, a general Description of the Empire of China and its Inhabitants.)

CANTON. JOHN, was 1 at Stroud July 31, 1718. Some advances made by him in mathematics and experimental philosophy induced his father to send him to London in 1737. He then tutored himself for five years to the master of a school, with whom he afterwards went into partnership and in this profession he spent his life.

On the invention of the Leyden phial he turned his attention particularly to electricity, and various discoveries of his not sufficiently marked to require biographical notice, though evincing great ingenuity, will be found in the references at the end of this article. He was the first who in England verified Dr. Franklin's idea of the similarity of lightning and electric fluid (July, 1752). He was then a member of the Council of the Royal Society, of which, in 1751, he received the gold medal for his method of making artificial magnets. [MAGNET.] In a paper communicated in 1753 he announced the discovery (which Franklin made about the same time) of clouds being in different states of electricity. In the following year he found that the quality of the electrical excitement made by rubbing any given substance depended on the rubber, as well as on the other substance. The common pith-ball electrometer, and the amalgam of tin and mercury used for the increase of the action of the rubber, are due to him. In 1762 he demonstrated the compressibility of water, in opposition to the well-known Florentine experiment. His experiment was repeated in the presence of a committee of the Royal Society, and a second gold medal was awarded to him in 1765. In 1769 he communicated experiments in proof that the luminous appearance of the sea arises from the presence of decomposed animal matter. He died March 22, 1772. There is a life of him by his son in Kippis's Biographia Britannica, abridged in Hutton's mathematical dictionary. His

imicated some new experiments for Priestley's Histories of Electrical and Optical Discoveries.

CANTON'S PHOSPHORUS. [PHOSPHORES.]

CANUTE. The rich, fertile, and beautiful island of Britain was a constant temptation to the inhabitants of the shores of the Baltic, and of the less genial country stretching thence to the north, forming the kingdoms of Norway and Sweden. These people, the Northmen as they were designated by the people of the more southern parts of Europe, possessed a navy which seems to have been far superior to that of any other state, and which enabled them to make at pleasure descents upon the coasts of all the countries bordering on the English seas. But it was not merely by predatory descents upon the coast that they harassed the English people during the reigns of the Saxon kings; but they also contested the field, and disputed with the native princes the entire sovereignty of the southern portion of the island. They had possessed themselves of the right of conquest of much of the northern coast of Britain, where they had a succession of princes, who became at length, in the person of William the Norman, monarch of a sovereigns of England.

Much of the history of the Anglo-Saxon kings is the history of the contests with these formidable neighbours. The genius and talents of Alfred for a while saved the country from being entirely conquered; but when he was dead, and was succeeded by a prince inferior to himself, the nation became so weak that it could make no effectual resistance. The Danes became settled in many portions of the island, tribute was paid to them, and finally, in the person of Canute, one of the greatest monarchs of this northern sovereignty, they accomplished that which they had so long desired, the entire subjugation of the Anglo-Saxon people, and the extinction for a time of the Anglo-Saxon sovereignty.

This then is the light in which we are to contemplate Canute: the king by birth and interference of the people now known as Danes, Normans, and Swedes, and as the man who accomplished the work of his father Sweyn in displacing the posterity of Egbert from the sovereignty of England. He reigned about twenty years (A.D. 1017—A.D. 1036), during which period the country was at peace. England of all his

possessions he chose for his usual residence. He died at Shaftesbury, and was interred at Winchester, the usual place of interment of the Saxon kings. Canute, successful in war, was, in peace, humane, gentle and religious. William of Malmesbury says of him, that by his piety, justice, and moderation, he gained the affection of his subjects, and an universal esteem among foreigners. The beautiful history of the rebuke which he gave to the flattery of his courtiers, a story which it would be an unreasonable scepticism to doubt, found as it is in some of our oldest and best chroniclers, makes his name and his virtue more familiar to the English nation than all the encomiums of our chroniclers, or than his acts of piety in his journey to Rome, and in the foundation of the two monasteries of Saint Bennet of Holme and Saint Edmund's Bury.

The reigns of the two sons of Canute were short and disturbed. In 1041 the posterity of Egbert, in the person of Edward, son of King Ethelred, regained the throne. This was Edward, called the Confessor. His reign was harassed by the Danes under Sweyn, another son of Canute. They also disputed the sovereignty with Harold, the son of Earl Godwin, who assumed the crown on the death of Edward: and England might have suffered much longer from attempts of the northern chiefs, had it not fallen under the sway of the race of Norman princes, who governed with a more vigorous hand than that of the Anglo-Saxon chiefs.

CANZONET, in music (*canzonetta*, Italian, a diminutive of *canzone*, or *canzona*, a song), a short song, one that is brief compared with the sacred airs of the oratorio or with the *aria* of the Italian opera. Formerly the term was applied to vocal music in parts: now it is confined to songs for single voice.

CAOUTCHOUC. This remarkable substance is produced by many different plants. That which comes from the tropical parts of South America is obtained from *Siphonia* (or *Herea*) *elastica*; and most other euphorbiaceous plants furnish it more or less abundantly. Various Urticaceæ yield it, especially *Ficus elastica*, and the rest of the genera of the Antocarpeous section; *Cecropia peltata* has even been asserted to furnish a large proportion of the American caoutchouc: but this is doubted by Humboldt, because its juice is difficult to inspissate. In Papantla it is yielded by a plant called *Ule*, which the Berlin botanists call *Castilleja elastica*. Several Apocynaceous plants secrete this matter: as *Urceola elastica*, in Sumatra; a species of *Tacca*, in Madagascar; and *Willughberia edulis*, in India; but the latter is of bad quality. Among Asclepiadaceous plants *Cynanchum latifolium* is asserted by Wallich to afford excellent caoutchouc at Penang.

Caoutchouc is generally termed Indian rubber from its use in removing pencil traces from paper, and sometimes, from its elasticity, gum elastic. In a state of purity this peculiar vegetable secretion is insipid and scentless, white, extremely elastic, inflammable, not altered by exposure to the air, insoluble in water and in alcohol, soluble in ether and in the essential oils, acted upon by alkalies, and decomposed by concentrated sulphuric and nitric acids. According to Dr. Ure's analysis it consists of three atoms of carbon and two of hydrogen; according to Faraday's, of eight atoms carbon and seven hydrogen, or carbon, 6·812, hydrogen, 1·000. When the impure caoutchouc of commerce is burned, a small quantity of ammonia is evolved; it therefore contains also azote.

Caoutchouc was introduced into Europe early in the last century, but its origin was unknown till the visit of the French academicians to South America in 1735. They ascertained that it was the inspissated juice of a Brazilian tree, called by the natives *Ihvé*; and an account of the discovery was sent to the academy by M. de la Condamine in 1736.

In order to obtain caoutchouc the trees which produce it are pierced in the rainy season, upon which a thick juice of a yellowish-white colour exudes, which becomes darker by exposure to the air. If this juice be kept in well corked bottles it may be preserved for some time without undergoing much change, and it has been imported in this state; but, however perfectly the atmosphere may be excluded, it will ultimately solidify. Heat coagulates the juice and separates the caoutchouc: alcohol and acids produce the same effect. If exposed to the air in thin films it soon dries, losing from one-third to one-half of its weight, and leaving caoutchouc of the usual appearance. By the natives of South America it is applied in successive coats to the surface of clay models of bottles and of animals, and dried

over fires, the smoke of which communicates to it a dark colour. While the caoutchouc is still soft various lines are drawn upon it with a blunt tool, which remain permanently impressed. When the whole has become dry, the clay is crushed and shaken out of the bottles.

The elasticity of caoutchouc is its most remarkable property; pieces of it may be stretched, after being soaked in warm water, to seven or eight times their original length, without being torn, or having their contractile power destroyed; and bottles of it may, by means of a condensing syringe, be expanded to many times their original dimensions. If a bottle be soaked in well washed sulphuric æther until quite soft, it may be inflated by means of the mouth till it has become so thin as to be transparent, and sufficiently light to ascend when filled with hydrogen gas. If dried in this state it will not again contract, and thin sheets of caoutchouc may be thus formed. A bottle has been thus expanded till it was six feet in diameter.

When exposed to heat caoutchouc fuses, but on cooling retains the consistency of tar. At a higher temperature it burns with a white flame and in the countries where it is produced is made into torches, which emit much smoke and an offensive odour. When it is distilled and the vapour condensed, it yields an amber-coloured fluid, which on being again distilled becomes colourless: this fluid has obtained the name of caoutchouine. It is extremely volatile, it is the lightest fluid known, and produces the heaviest gas known. A small quantity poured into a tall glass vessel speedily evaporates and fills the glass with gas, and as the gas is very heavy it remains in the glass. On applying a light, the surface of the gas takes fire and burns gradually to the bottom of the vessel. These results of distillation are olefant gas and carburetted hydrogen. Alkali destroys its texture, sulphuric acid decomposes it, and it is converted by nitric acid into oxalic acid. Although insoluble in water, yet, if strips of caoutchouc are wound spirally round a metallic rod, so that the edges are in contact, and then boiled for some hours, the edges will soften a little and adhere, and a tube of caoutchouc will be formed.

In æther caoutchouc readily dissolves, and on the evaporation of the æther it remains unchanged in any of its properties. For this purpose the æther is washed by agitating it in a bottle with twice its bulk of water. The bottle is allowed to remain inverted till the æther has been separated from the water and risen to the surface, and the water is then allowed to run out, leaving the caoutchouc in the vessel. This process is to be repeated three times, when about one third of the original quantity of the æther will remain. The caoutchouc is to be boiled in a cup for 24 hours, and then placed with the rest in a well closed vessel, and in the course of a few days it will dissolve completely.

The volatile oils dissolve caoutchouc but on evaporation generally leave it in a glutinous state; if, however, alcohol be added to its solution in oil of turpentine, the caoutchouc separates in a semi-fluid state, and by exposure to the air regains its firmness and elasticity. Naphtha or petroleum rectified into a colourless liquid dissolves it, and upon evaporation leaves it unchanged.

In South America the natives have long made waterproof boots of caoutchouc, and by imbibing cloth with the milky juice of the hêve have rendered it impervious to moisture. In Europe caoutchouc is also used extensively in the manufacture of water-proof cloth. For this purpose it is usually dissolved in the oil distilled from gas-tar, and spread upon the surface of a piece of the cloth, upon which a similar piece is then extended, and the whole passed between a pair of rollers. Thus the fabric consists of two pieces of cloth with a layer of caoutchouc interposed, and uniting them together. The cloth thus prepared is so impervious to moisture and to air, that floating or hydrostatic beds for invalids are formed of it, and even beds and cushions are rendered elastic by inflating them.

Caoutchouc is used in the manufacture of braces, of some surgical instruments, and of many other articles for which its elasticity renders it adapted. It is also cut by machinery with great rapidity into very fine thread, to which a still greater degree of tenuity is given by stretching it, as it is wound tightly upon bobbins, where it is allowed to remain till its contractile power is lost. This thread is woven into a variety of ornaments and elastic fabrics.

(*Ann. de Chimie*, xi.; *Journ. of Science*, xxi.; *Do. N. S.*, vi.; *Repertory*, xvi., and other vols. of do.)

Mineral Caoutchouc is a term sometimes but improperly used to denote the elastic varieties of petroleum.

CAPACITY, the same in sense as **CONTENT** or **VOLUME** in pure mathematics. In physics it generally signifies power of holding or retaining. Thus we speak of the capacity of a body for heat, &c.

CAPE, literally *Head*, (*Cap*, French; *Capo*, Italian; *Cabo*, Spanish and Portuguese; all from the Latin *Caput*;) is a term used to indicate the extremity of a portion of the coast which projects beyond the general line of the shore. On rocky and much-indented coasts, as on that of northern Scotland, capes are, of course, very frequent, while low and sandy coasts sometimes offer no cape for 50 or even 100 miles. On shores of the latter description they are commonly formed by the change in the trending of the land, and form obtuse angles, while on rocky coasts they terminate in acute angles, on which account they are called **Points**.

CAPE BRETON, an island of North America, situated to the E. of Nova Scotia, and forming the S.E. limit of the Gulf of St. Lawrence, between 45° 27' and 47° 4' N. lat., and between 59° and 61° 35' W. long. Its greatest length from N. to S. is about 100 miles, and its greatest breadth 55. The shape of the island is something like an irregular triangle, the apex of which forms the northern and narrowest part of the island. Its area, exclusive of the great salt water lake, is about 2,800,000 acres, more than one-half of which is supposed to be fit for cultivation.

Cape Breton is divided into the mainland of Nova Scotia by the Gut of Canso, and St. George's Bay; the former is a channel 2½ miles long, and varying from ½ to one-and-a-half in width. St. George's Bay is at the N. extremity of this channel. North Point is about 73 miles from Cape Anguille, the S.W. extremity of Newfoundland.

The island of Breton contains much high land, which appears in the form of several ridges of hills, particularly in the N. part, and on the E. and N.W. districts near the coast. Cap. Enfumé, on the N.E. coast, in lat. 46° 40', is 1500 feet above the level of the sea.

The E. and S. coasts are well provided with harbours. Saint Ann's Bay, on the E., leads through a narrow passage to a safe and capacious harbour of the salt water, in which ships of considerable burthen may anchor. This bay, 1½ miles wide and 4 miles long; which then separates into two narrow arms, one of which runs to the S.W., the other to the S.E.; at the bottom of the latter of these arms is a small bay, the town of Sydney, the capital of the island.

This bay is safe and spacious. It has a depth of 10 fathoms at its mouth, but with sufficient depth of water for ships to enter. South of Sydney harbour are Lunenburg, Wm. Murgain, and Miné bays, which last is the outlet of the river, which flows into it from the W. On the S.E. coast are Louisbourg Harbour, Gabarus Bay, Portland Cove, Fort of Harbour, and St. Eustace Harbour. St. Peter's Bay is on the S. coast, and in Lenox channel leading to the Gut of Canso. The only harbour on the W. coast which will admit trading vessels is Port Hood, situated at the N.E. point of St. George's Bay; this harbour is capacious, and completely sheltered. The most remarkable physical feature of the island is the Bras d'Or, an inland sea, which occupies a large portion of its surface, and nearly divides it into two islands. The entrance to this basin is by two channels, one by the island of Boulardrie, which lies between St. Ann's and Sydney harbours on the E. coast. The N. channel is called the Great Entrance, and the channel on the S. side of the island the Little Entrance; the last is capable for ships, having a sunken bar at the mouth, and is seldom used even by boats. Boulardrie island is 20 miles long, and its greatest breadth is 2 miles. Within this island, the Little Bras d'Or, a passage to the W. of which leads to Bedeque Bay and Wyecoomagh Basin, which are together 13 miles long. Another narrow passage at the S. extreme of the Little Bras d'Or conduits to the large basin, which contains numerous small islands, and branches out into numerous arms or inlets. The most southern of these arms terminates at the isthmus of St. Peter, a neck of land only 900 yards across, which separates the water of the Bras d'Or from the Atlantic, at the Bay of St. Peter in Lenox Channel.

The Bras d'Or receives the waters of several rivers, the principal of which are the Bedeque and the Waganatcook on the N., and the Dennys on the W. From the mouth of the Great Entrance to the S.W. extremity of St. Peter's

isthmus, this inland basin is 5½ miles long, and its width from E. to W. at the broadest part is 20 miles. The depth of water varies from 70 to 360 feet, and in every part it is safely navigable, offering great commercial advantages to the island by affording water-communication, which enables the farmers of every district to dispense with a burdensome land-carriage for their produce.

The island contains several fresh-water lakes. In the N.W. division is Lake Marguerite, 40 miles in circumference, the outlet of which is by a river of the same name 15 miles long, which falls into the sea opposite East Cape, or Prince Edward's Island. Grand Lake, and Miré river or lake, are in the S. division; the latter receives the waters of Salmon river, which flows from the W. There are likewise many small streams on different parts of the coast which are not navigable.

The climate of Cape Breton is not so regular, but neither is it so rigorous as that of the neighbouring continent. The frost does not usually set in long before Christmas; and, instead of lasting without intermission until the end of April, as on the mainland, there are frequent intervals of warmer weather, sometimes for a fortnight together, before the frost returns. Very intense cold is however occasionally experienced, and it is not uncommon to see Fahrenheit's thermometer at 20 degrees below zero. The summer months are dry and warm on the eastern coast, but on the western coast there is more moisture. The mean summer heat is 80° Fahr. in the shade. The spring, as in most cold countries, is short, and vegetation is exceedingly rapid. Planting and sowing are done in May, fruits ripen in July, and the harvest is got in in August and September.

Mica slate, clay slate, sienite, and primitive trap, are found in all parts of the island. Transition limestone, greywacke, gypsum, and coal, are very generally distributed. The coal-fields are of great extent in the S.E. division. Neither the extent of the coal-fields nor the quality of the coal has been ascertained to the north of Bras d'Or. Coal is known to exist in the west part of the island; and it has been calculated that the available seams of coal in different parts occupy an area of 120 square miles. That which has been worked is of good quality. Extensive works are now carried on at Sydney and at Lungan, where the seams vary in thickness from 3 to 11 feet; upwards of 40,000 tons were raised in 1832, more than half of which quantity was exported to the United States. Granite prevails among the primitive rocks S.E. of the Bras d'Or. Gypsum is found in great abundance in many parts, and particularly on the shores of the Bras d'Or. There is a high cliff of gypsum on the island of Boulardrie, which is carried off on board large vessels that convey it to the United States; great quantities are likewise shipped every year from Bedeque and Whycoomagh bays, and from Plaster Cove on the Gut of Canso. There are salt springs at Bedeque, at Whycoomagh, at Wagamatcook, and in some other parts on the Bras d'Or; the brine produces from 10 to 12 per cent. of salt. Iron ore is found abundantly associated with the coal about Sydney, Lungan, and in other places. Some of the ore will, it is said, yield 60 per cent. of the metal.

The principal vegetable productions of Cape Breton are timber, the common cereal grains, including maize, and potatoes. The timber is of the same kind as is found in the N. parts of the mainland of N. America—the pine, birch, oak, spruce, hemlock, beech, ash, maple, and elm. Considerable shipments of timber are made yearly to the United Kingdom, chiefly from the neighbourhood of Bedeque Bay and Whycoomagh basin. The produce of grain, &c., in the year 1827, the latest of which any correct official return has been made, was as follows:—29,851 bushels of wheat; 31,837 bushels of other grain; 468,507 bushels of potatoes; 15,159 tons of hay. The number of acres in crop in that year was 35,677. In the same return the number of stock is thus given:—1123 horses; 16,821 horned cattle; 23,644 sheep; and 8785 swine. A return professing to give these particulars is made every year by the officers in the colony to the home government, but the same figures have been given year after year for several years past without any explanation.

The population of the island, according to a census taken in 1827, amounted to 9435 males, and 9265 females, together 18,700 souls. The number of births in the same year was 683, of marriages 128, and of deaths 216. It would appear that this enumeration must have been incorrect, or that the population must have very greatly increased since 1827. The official return of 1834 states the number of officers and

men enrolled in the island militia to amount to 6552 persons; and presuming that every male inhabitant between the ages of 15 and 60 was included in that number, the total population represented by them must have amounted to at least 26,000 souls.

The coasts and harbours swarm with fish. Those most commonly taken are salmon, cod, herrings, mackerel, shad, halibut, sturgeon, alewives, soles, plaice, haddock, and smelts. In the lakes and rivers, perch, trout, bream, and eels are abundant. A considerable number of the inhabitants are engaged in the fishery, the produce of which forms one-third of the value of the total exports from the island.

The first settlement was made on this island in 1712 by the French, who gave to it the name of *Isle Royale*. In 1720 they constructed the fortifications of Louisbourg, on the S.E. coast. In 1745 the island was taken by a body of British troops from New England, since which time it has continued in the possession of this country. At the time of the capture the works of Louisbourg were destroyed by order of the English government, and the settlement at that spot has since been altogether deserted. The town of Sydney, now the capital of the island, is situated, as before described, at the bottom of a deep inlet on the E. coast. It was founded in 1822, but its growth has not been considerable; the latest accounts describe it as containing not more than 70 houses, and a population of 500 souls. The town is laid out with regularity, and the houses are neatly built, each having a garden attached to it. The courts of law are held in Sydney, where also the different government officers have their residences. The other settlements hitherto made on Breton Island are situated either on the sea-coast, or on the margin of the Bras d'Or; the interior may be considered as unoccupied. Most of the smaller settlements on the coast have been made by fishermen; many of these are the descendants of the Acadians, or original French settlers from Nova Scotia. The European inhabitants, who occupy themselves in agriculture and in the timber trade, are principally emigrants from Scotland and Ireland; some few inhabitants are the descendants of American loyalists.

The island, which is considered as a county of Nova Scotia, and is included within its government, is politically divided into three districts—S., N.W., and N.E., without any respect having been paid to its natural divisions. The N.W. district is sub-divided into four, and the N.E. into three townships. The S. district, which is much smaller than the others, is not sub-divided. The island sends two representatives to the Nova Scotia House of Assembly.

The greater number of the inhabitants, including most of the Scotch who came from the Highlands, are of the Roman Catholic religion. There are a few Presbyterians, and some members of the church of England, who are under the spiritual care of the bishop of Nova Scotia.

A few Indians, about 300 in number, still remain in the island. Their principal employments are hunting and fishing, but tracts of land have been reserved for them, upon which they grow maize and potatoes. They are quiet and unenterprising, generally remain stationary at their settlements during the winter, but wander along the shores at the return of warmer weather.

Legal provision is made for the support of the poor. The rate levied upon the inhabitants for this purpose in 1834 amounted to 1837. 16s. In the same year a further assessment of 4977. was made in order to defray county charges for the support of the police and for local improvements.

The total imports of the colony in 1832 amounted, according to the custom-house valuation, to 18,072*l.*, and its exports to 31,891*l.* About one-fifth of the imports consisted of corn and flour from the United States in return for coals. The remaining imports were of produce from the West India colonies in return for fish, and of British manufactures in return for timber.

Ship-building is carried on to some extent as well for colonial purposes as for sale in England. As many as 50 ships and brigs, besides schooners and smaller vessels, have been launched in one year. The number of registered vessels belonging to Cape Breton in 1828 was 346, varying in burthen from 30 to 200 tons.

Accounts are kept at the custom-house and the different government offices in sterling money, but in the commercial transactions of the inhabitants Halifax currency is used, 100*l.* of which is equal to 90*l.* sterling. The only gold coins current are the doubloon, and its parts. The doubloon passes for 16 dollars, or 4*l.* currency. The silver coins are

the Spanish dollar (passing at 2s. currency) and its parts, and English crowns, half-crowns, and shillings, which bear a proportionate value. Part of the circulation of the colony consists in notes issued under the authority of the provincial parliament.

(Macgregor's *British America*; Bouchetto's *British Dominions in North America*; *Government Statistical Tables*, part 3, supp.)

CAPE COD. [MASSACHUSETTS.]

CAPE FEAR. [CAROLINA, NORTH.]

CAPE OF GOOD HOPE, one of the most southern points of Africa, was discovered by Bartholomew Diaz, the Portuguese navigator, in 1493. Diaz, after exploring the Atlantic coast of Africa as far as Capedass Voltas, 29° S. lat., was driven out to sea by a storm, and the next land he saw was Algoa Bay. He had thus doubled the S. extremity of Africa without knowing it. On his way back he saw the cape, since called the Cape of Good Hope, to which he gave the name of Cabo Tormentoso, or Cape of Storms. On his return home the king of Portugal gave it the name of Cape of Good Hope, as an omen that the Portuguese had now a fair prospect of reaching India, the great object of their maritime expeditions. Vasco de Gama doubled it in November, 1497, on his way to the Indian seas, and from that time the Portuguese considered it as the S. extremity of Africa. But Africa does not terminate in a point; it presents to the S. Ocean a broad line of coast running E. and W., from 18° 23' E., the longitude of the Cape of Good Hope, to about 26°, which is the longitude of Algoa Bay. This coast is indented by several bays and forms several promontories, of which the Cape of Good Hope is the most westward, but Cape Agulhas, 26° 10' E. long., advances furthest to the S., being in 34° 15' S. lat. The Cape of Good Hope is in 34° 22'.

The Cape of Good Hope is the S. extremity of a narrow peninsula about 30 miles long, formed by False Bay on the E., Table Bay on the N., and the Atlantic on the W. Cape Town is on Table Bay on the N. coast of this peninsula, and Simon's Town is on False Bay. This peninsula was the original boundary of the settlement which the Dutch made here about the middle of the seventeenth century, but they soon extended themselves beyond the isthmus which joins it to the African continent. The Hottentots, the natives of this part of Africa, a mild and inoffensive race, were easily though gradually subdued by the Dutch, who encroached step by step upon their country, reducing them to the condition of serfs, or driving away before them the more stubborn tribes. This process continued for more than a century, until at last the Dutch occupied the whole country as far as the great ridge called Nieuwveld Bergen and Sneeuwbergen, about 32° S. lat., which runs E. and W., nearly parallel to the S. coast, and divides the waters that run to the S. from those which flow N. into the Orange River. [BETCHOUANA.] This ridge, the higher summits of which are about 9000 feet above the sea, and are covered with snow the greater part of the year, forms the natural boundary of the Cape colony, although the political boundary stretches considerably farther, the back settlers having extended beyond it on several points through the districts called by the Dutch Onder Roggeveld, Agter Roggeveld, and Middle Roggeveld. North of the limits of the colony, and between it and the Orange River, are the wandering Bosjesmans, the Griguanas, or bastard Hottentots, a mixed race, who have attained through the missionaries a considerable degree of civilization, and the Koranna Hottentots. The latter are one of the few Hottentot tribes that have retained their independence. They wear the old sheep-skin dress, and preserve the original customs of their nation, which were described by Kolben a hundred years ago, but which the Hottentots in the colony have long since abandoned and forgotten. They live in kraals; their huts are constructed of mats stretched over a frame of sticks in the shape of a bee-hive, and are easily removed on their pack-oxen as they migrate from place to place. Their huts are very dirty, and swarm with vermin. They are altogether in a very low state both of mental and physical refinement, much lower than the Caffres. They are however a good-natured, and, on the whole, a good-looking race, having many of them fine formed heads and prominent features. They lead an indolent wandering life, living chiefly on the milk of their cattle, and seldom roaming far from the banks of the Gariep and its tributary branches. Their cattle are smaller than the colonial breed, and much

resemble those of the Betchouana and Caffre tribes. Some of their kraals possess also goats and sheep. (Thompson's *Travels and Adventures in South Africa*.)

To the N.W., along the Atlantic coast, the colonial territory extends as far N. as 29° 40' S. lat. The Nieuwveld range makes a bend towards the N. at about 31° E. long., where it assumes the name of Roggeveld Bergen, and runs parallel to the Atlantic coast, leaving a broad belt of lower terraces and valleys between it and the sea. These form the various districts called Roggeveld Karroo, and Lower Bokkeveld and Cold Bokkeveld, which are watered by the Oliphant's River and its affluents. This part of the country is chiefly pasture-land. The Oliphant's River enters the Atlantic at about 31° 40' S. lat. At the N.W. extremity of the colony is the mission of Kamiesberg, and beyond it is the territory of the Little Namaqua Hottentots, who live between Kamiesberg and the Orange River. The missionary settlement of Pella is in Little Namaqualand. Beyond the Orange River are the Great Namaquas, who are said to extend 200 miles to the N., towards the country of the Damara Caffres. The Namaquas resemble the Korannas in their habits and mode of life. Great Namaqualand is watered, or rather drained, by a stream called by Vaillant the Fish River, and erroneously described in his and Burchell's map as falling into the sea to the N. of Angra Pequena. This river flows southwards into the Gariep, which it joins about 30 miles above the sea. (Thompson and the Rev. John Campbell have given some account of the Namaquas.)

The principal part of the colonial territory stretches to the eastward of Cape Town, and as far as the Caffre frontier, which was until lately fixed at the Keiskamma River, a little beyond the Great Fish River, about 27° E. long. In consequence of the last Caffre war (1835) the eastern boundary is now fixed at the Great Key River, which runs in an oblique direction between 28° and 29° E. long., giving thereby to the colony a length of about 10° of long., upon an average breadth of 2° of lat. The whole colony is a land of terraces, rising one above the other from the coast, divided by almost parallel ridges, and intersected by numerous ravines or beds of torrents, which contain little or no water during the summer months. The want of perennial springs, and the consequent dryness of the soil and scarcity of water for cattle, constitute the principal deficiencies of the colony. The rivers are too

their current too rapid for the purposes of navigation; two-thirds of the land is destitute of vegetation the greater part of the year. The upper terrace stretches at the foot of the Nieuwveld Bergen for nearly 100 miles in length E. and W., and between 80 and 100 in breadth N. and S., is called the Great Karroo, and is one of the most barren and desolate spots imaginable. Owing to its elevation, which is 3000 feet and upwards, it is bleak and cold in winter. The soil is a sand mixed with clay containing particles of iron, which gives it a yellowish color; all soil of a similar colour in other parts of the colony is called by the name of Karroo ground. The new

settlement of Beaufort is in the N. part of the Great Karroo, in a valley at the foot of the Nieuwveld Bergen. To the E. of the Great Karroo is the settlement of Graaf Reynet, at the foot of the Snow Mountains. Graaf Reynet is wonderfully improved of late years; it is now a handsome village of 300 houses, almost all of which are neat and commodious brick buildings, and some of them even elegant. The streets are wide, laid out at right angles, and planted with rows of lemon and orange trees. Each house has a large allotment of ground behind it, in some instances of several acres, which is laid out in orchards, gardens, and vineyards. These are all watered by a canal from the Sunday River, which branches out into a number of small channels, and each inhabitant receives his due portion at a regular hour. The population of Graaf Reynet, of all colours, amounts to about 1800. The town is built in a sort of basin, almost encircled by the deep channel of the Sunday River which flows down to Algoa Bay, and is closely environed by an amphitheatre of steep rugged mountains. Formerly a considerable trade was carried on between this place and Cape Town by means of bullock waggons which crossed the Great Karroo desert in the winter or spring, and returned before the summer heats had destroyed the vegetation and dried up the springs and rivers. By this road the Cape butchers still procure a large proportion of the sheep and cattle which are wanted for the use of Cape Town and the

shipping in Table Bay. But of late years most of the merchandise required by Graaf Reynet, which is a sort of emporium for a large extent of country, is brought by coasters to Algoa Bay and forwarded by waggons from that port. This reduces the land carriage to about one-third of the distance through the Karroo. Graaf Reynet owes much of its prosperity and embellishment to Captain Stockenström, a native colonist, and the landdrost or magistrate of the district, which, though far the most extensive and the wildest in South Africa, is one of the best administered. He has established an Agricultural Society to promote emulation and European improvements among his countrymen. There is at Graaf Reynet an English teacher to teach the English language and the classics; and also a day school for females. Captain Stockenström placed his own library in one of the school-rooms for public use. (Thompson's *Travels*, 1827.)

To the E. of Graaf Reynet is the village of Cradock, in the new district of Somerset, on the Great Fish River, which includes the border territory on the Caffre, rather well new Scotch locations or settlements. It is a good grain country. The Gonaqua Hottentots, of whom Van Riebeeck speaks, lived in this neighbourhood. The tribe is now extinct. Lower down towards the coast, and between the Fish River and Algoa Bay, is Graham's Town, a well-peopled town and the Drosdy or capital of the Albany district, with about 2500 inhabitants chiefly English. [ALBANY.] Graham's Town is the chief place in the E. part of the colony, and far head-quarters of the military on the Caffre frontier. Bathurst is another settlement near the mouth of the E. River. Port Elizabeth in Algoa Bay is the shipping and landing-place for the E. part of the colony, but is far from safe. Inland to the W. of Algoa Bay a long ridge, known by the general name of Zwart Bergen, or Black Mountains, which in some places rises 1000 feet above the sea, runs parallel to the coast, forming the S. boundary of the great Karroo plain. Between it and the coast are several terraces, one below the other, down to the sea shore. These are known by the name of Longenkloof, Bankenskloof, &c. In this part of the country, between the Gamtoos and the Gauritz rivers, the sides of the mountains are covered with majestic forests, a thing very rare in the rest of the colony, which is generally without wood. These forests supply, not only Cape Town, but also a great part of the inland districts, with timber for building and other purposes. It is shipped at Port Elizabeth, the mouth of the Knysna, for Cape Town. There is a fine natural harbour, in which it is easy for large ships might lie at anchor secure from all winds, but the entrance is narrow and rather dangerous. The want of good harbours is a great drawback upon the colony. W. of the Gamtoos river is the district of Zwellendam, the soil of which is well fitted for the cultivation of corn. The rain falls in the season of it, and the soil is so fertile that it can be cultivated with less labour than it is to the north of the Zwart Mountains, which intercept the refreshing showers brought by the S.E. wind. The Breede river, which falls into the Port of Beaufort, and is navigable for vessels of 200 tons, affords great advantages to the trade of this district. As yet, however, the cultivation of corn is mostly limited to the more western Cape district, the produce of which comes chiefly by land to Cape Town, or is shipped at St. Helena bay, from the country in that neighbourhood. The district of Stellenbosch, immediately E. of the Cape district, along the skirts of the chain of Hottentots' Holland mountains, and within a distance of from 30 to 40 miles from Cape Town, is the principal wine district in the colony: the wine farms begin at Hottentots' Holland and continue through Stellenbosch, Banyhook, Franschoek, Drakenstein, and the Paarl to Waggonmakers Valley. These produce the common wine called Cape Madeira and Portae. The skirts of Table Mountain, the farm of Constantia and its neighbourhood, Hout's Bay, and Tiger Bay, are the finer wines. Exclusive of the Cape and Stellenbosch districts, all the rest of the colony may be considered as nearly a grazing country. The Dutch farmers, who are called Boers, as they are called, have been long settled as indolent, rude, and repulsive in their habits. They have, however, given a somewhat more favourable account of themselves. The want of markets for their surplus produce, the badness of the roads, and the unfavourable nature of the soil and climate in many parts, may account for their indolence. They produce all they want for their

consumption, and their houses appear to be well stocked with provisions. Hospitality to strangers is general. Their harsh treatment of the poor Hottentots, and the deeds of violence perpetrated against the Boesjesmans near the frontiers, exhibit the worst parts of their character, though the shooting of the Boesjesmans, it ought to be observed, is often done by them in self-defence.

The wild animals of the colony are, the lion, leopard, hyena, rhinoceros, the wolf, and jackal. They, however, as well as the elephant, have much decreased in number, having retreated before the advancing steps of civilized man. In the more secluded parts of the interior spring-bucks are numerous, as well as ostriches; quaggas and giraffes are also found. The black eagle of the Cape, and the huge vulture or condor, are seen in the mountains. (Lichtenstein, Thompson, and the Rev. J. Campbell.)

Statistics.—The population of the different districts of the colony in 1831 was as follows:—

	White and free coloured persons		Negro apprentices, formerly slaves.		Total.	
	Male.	Female.	Male.	Female.	Male.	Female.
Cape	6,642	7,124	2,861			9,844
	4,173	3,734	2,515	2,245	6,688	5,979
Albany	4,181	3,674	5,465		9,646	7,653
	5,713	5,631	2,649		8,402	7,910
Worcester	6,810	6,441	1,736	1,517	8,546	7,958
	3,286	2,749	1,175	1,161	4,461	3,910
	5,135	4,485	727	672	5,862	5,157
	6,309	4,706	771	674	7,080	5,380
Graaf Reynet	11,840	13,028	1,594	1,235	13,434	14,263
Total	60,410	56,418	19,580	16,589	80,000	73,007
					133,007	

Slavery was abolished in the Cape colony by the act, which came into operation on August 1st, 1834.

According to the official returns the number of births in 1834 was 5071, or 1 in 30 of the population; of marriages, 810, or 1 in 189; of deaths, 2053, or 1 in 74. This rate of mortality is so much more favourable than in other countries that it is not possible to give full credit to the statement. The colony has received annual accessions to its numbers since the year 1820, when the English government first encouraged the settlement of emigrants from the United Kingdom. The number of settlers in the various years have been

1820	1063	1825	114	1830	201
1821	401	1826	116	1831	59
1822	192	1827	114	1832	202
1823	184	1828	135	1833	517
1824	119	1829	197	1834	288

The numbers of public schools and of children taught therein in the several districts in 1834 were as follows:—

	Schools.	Males.	Females.	Total.
Cape Town	4	141	127	268
Cape District	8	271	267	538
St. Nicholas	3	60	33	93
Worcester			35	87
Zwellendam				133
George		29	17	46
Uitenhage		125	42	167
Albany		76	28	104
Somerset		55	61	116
Graaf Reynet		47	28	75

1627

There are also 53 private schools in the colony, but the great distance at which many of the inhabitants of this thinly peopled colony reside from any school obliges those who can afford it to employ private teachers in their families. In such cases other children whose parents reside in the same neighbourhood partake in the instruction.

The extent of land in cultivation, distinguishing pasture from arable, and of uncultivated land, as well as the number and descriptions of stock, and of various kinds of produce as stated in the returns for 1834, are given in the following table. No general survey of the colony has been made. The estimated number of acres granted to individuals is about 18 millions, besides several "loan places," for which no arrangements as to quit-rents have been made. The extent of land still ungranted is computed at more than 50 millions of acres, exclusive of the reserved territory in which there are native settlers.

	Land in cultivation.		Acres of uncultivated land.	Number of Stock.				Kinds and Quantities of Produce.									
	Pasture.	Arable in crop.		Horses.	Horned cattle.	Sheep.	Goats.	Bushels of wheat.	Bushels of barley.	Bushels of rye.	Bushels of oats.	Pounds of mutton.	Pounds of beef.	Pounds of butter.	Pounds of cheese.	Pounds of tallow.	Pounds of soap.

The number of mills and manufactories of various kinds in the different districts of the colony were returned as under in 1834:—

	Water Mills	Windmills	Horse Mills	Tanneries	Hat Manufactories	Breweries	Candle Manufactories	Snuff Manufactories	Sawing Mills	Tile Kilns
6	1	9	1	2	1	3	1	1	1	1

In Cape Town there are also one steam mill, two distilleries, one soap manufactory, and one iron foundry; a cutlery manufactory in Zwillingdam; and a rope manufactory in Stellenbosch.

The fisheries form an important branch of industry in those districts which are on the coast. In 1834 the whale

fishery produced 23 black whales and 30 tons of spermaceti oil; the value of the whole being 59,000. This fishery is carried on in boats of from two to seven tons burthen each. About 50 such boats are employed in the whale and other fisheries in Table Bay alone. Every settler whose farm is situated on the sea-coast keeps a fishing-boat for the supply of his own family.

The trade carried on with the natives in the interior of the country has not only much increased of late, but has essentially altered its character. The medium of traffic on the part of European settlers was formerly made up of beads, buttons, and other worthless articles of the like description, but the natives now in exchange for their hides, horns, and ivory, demand blankets, woollen cloths, iron, and various domestic utensils and tools made of that metal. This trade, which formerly was of a very fluctuating character, has now become as regular as that carried on between any commercial people, and is continually growing in amount.

The extent of the external trade of the colony may be seen from inspection of the following tables, which state the number and tonnage of shipping arrivals and outwards from various parts of the world, and the money value of the goods which they conveyed, in 1834.

CAPE TOWN, the capital of the colony of the Cape of Good Hope, is in 33° 50' S. lat., and 18° 21' E. long.; at the foot of Table Mountain, on the shore of Table Bay, from which the ground rises with a gentle slope towards the mountain.

Cape Town was founded by the Dutch in 1650, and, together with the colony, continued in their possession until 1795, when it was taken by the English. At the peace of Amiens it was restored to the Dutch, but was again taken by the English in 1806, and has since remained in their possession. The town is well and regularly built. The houses, which are for the most part of a good size, are nearly all of red brick or stone, and furnished with a verandah in front. The principal streets are wide and clean, and regularly laid out, intersecting each other at right angles, and shaded with oaks and elms.

The castle is on the right-hand side of the town looking towards Table Bay, the anchorage in which it commands. This fortress is of considerable strength. Its form is pentagonal, and it has a broad fosse and regular out-works. Many of the public offices of the colony are within its walls, which likewise contain barracks capable of holding 1000 men. Connected with the castle on the E. by a rampart called the sea-line is Fort Knokke, and still further E. is Craig's Tower and battery. On the W. side of the town, and surrounding the hill called the Lion's Rump, are Chavonne, Amsterdam, and Rogge batteries; and, besides these, the entrance to the bay is commanded by a battery called the Mouille.

Table Bay is sufficiently capacious to contain a great number of ships, but it is exposed to a heavy swell during the prevalence of the westerly winds in June, July, and August. At other times the anchorage is tolerably safe. When discharging or taking in goods ships are moored very near the jetty or landing place, which is built of wood, and is at the E. side of the town. Vessels that touch at the port for water and refreshments only anchor farther out, and if provided with a chain cable ride at single anchor with 80 or 90 fathoms of cable, to counteract the effects of the swell. If provided only with rope cables it is necessary to ride with a bower-anchor and a kedge, and to have another bower-anchor always in readiness to let go.

Cape Town contains four Protestant churches and a Roman Catholic chapel. Of the former, St. George's church, in which the English episcopal form of worship is celebrated, is capable of containing 1160 persons. The Dutch Calvinistic church will hold 1800, and the Lutheran church 1400 persons. The Presbyterian form of worship, according to the church of Scotland, is performed in St. Andrew's church. The ministers of all these places of public worship are supported by the colonial government.

The supreme court of justice for Cape colony is held within the town under the presidency of a chief justice and two puisne judges; there are besides a magistrates' court and a police office, having a judge and superintendent and a deputy.

The plain which surrounds Table Mountain is composed of blue schistus, interrupted by masses of blue flinty rock, and resting upon a tenacious clay impregnated with iron; the colour of the clay varies from pale yellow to deep red, and abounds with brown foliated mica, interspersed with blocks of granite. Rising from the base of Table Mountain are beds of vertical schistus; over these are veins of granite, varying in thickness from less than an inch to six feet. After ascending 900 feet the mountain appears to be nearly a solid mass of granite, characterised by large crystals of felspar, and containing, besides quartz and mica, occasional masses of hornblende. After ascending 900 feet higher the granite ceases, and is surmounted by thin horizontal strata of red sandstone, which formation continues for near 200 feet, and is then succeeded by a more indurated sandstone, quite white, and containing imbedded in it pieces of quartz from the size of a pea to that of an apple; this formation continues to the summit of the mountain, which is 3567 feet above the level of the sea.

An observatory has been established at Cape Town under the control of the lords of the Admiralty. Its situation is to the N. of the town, about two miles from it, and rather more than a mile from the sea-shore.

CAPE HORN, which is considered the southern extremity of America, is not a part of the continent, but is the most southern point of a small island which belongs to the extensive group commonly called *Tierra del Fuego*. It is situated about 56° S. lat. and 67° 10' W. long., and consists of a high precipitous black rock, which is conspicuous above all the neighbouring land, utterly destitute of vegetation, and running far out into the sea. The strong W. gales which blow in the neighbourhood of this cape render it difficult to be doubled from the east. A century has not yet elapsed since the expedition under Lord Anson was partly destroyed in the attempt, and the Spanish fleet under Pizarro was entirely lost in doubling Cape Horn. But the improvements in navigation have stripped this cape of its terrors, and the passage may be effected with comparative ease and certainty. Gales from the west blow during the summer (October to April) nearly without interruption, but only near the Cape; in 60° S. lat. they are more variable. During the winter east winds are more frequent; but at that season the navigation is rendered dangerous by the floating islands, which approach the Cape, and are found even farther to the north. Capt. B. Hall did not find the east current near it greater than may be attributed to the effect of the west gales. (Capt. Basil Hall.)

CAPE VERD ISLANDS (*Lhas Verdes*) were so called by the Portuguese because the sea to the west of them is covered with Gulf-weed, so as to present some resemblance to extensive meadows. This group of islands is about 300 miles from the western shores of Africa, between 14° 17' and 17° 19' N. lat., and between 22° 10' and 23° 10' W. long. Their shores are commonly low, or of moderate elevation, but in the interior the islands often rise to a considerable height. They are doubtless of volcanic origin, and a volcano

still exists on the Island of Fogo. The soil is very dry, but by no means sterile. The rainy season lasts from July to November, and is attended with thunder-storms and thick fogs. Sometimes no rain falls for three or four years together, and the consequence is a famine. During the rainy season, the climate is unhealthy. Indian corn and rice are the principal objects of agriculture; but all the fruits of the south of Europe and of western Africa grow abundantly, especially oranges, cocoa-nuts, and pine-apples. Melons come to great perfection, and also grapes, but the inhabitants are not permitted to make wine. Sugar and cotton are grown, but very little is exported. Among the domestic animals the most numerous are goats and fowls; goat skins are the principal article of export, upwards of 6000 being annually shipped. Asses are also numerous, and are exported to the West Indies. The most remarkable of the wild animals are monkeys and bism-cats; turtles are found in the neighbouring seas in great numbers. Salt is made in most of these islands on the low shores, and constitutes one of the principal articles of export; it goes to North America. The inhabitants, who are stated to amount to between 40,000 and 50,000, are mostly negroes, mixed with some mulattoes, the descendants of the Portuguese who have settled here. There are very few whites. The inhabitants are Catholic Christians, and great zealots; their general language is the Portuguese. Vessels bound for the East Indies stop here for fresh provisions, but not so frequently now as formerly.

This group consists of 14 islands, 9 of which are inhabited. Branca, Chaon, Carnera, and Ghua, are bare rocks, and Ilha do Sal has a sterile soil, but is important for the great quantity of salt collected in the numerous lagoons with which its beach is covered, and which is formed by solar evaporation. The surface of the whole group is calculated to be about 1700 square miles.

S. Jago, the largest island, is about 50 miles long, and nearly 24 broad in the widest part: its area is 770 square miles, and population above 12,000 souls. The capital, Ribeira Grande, or S. Jago, where the Portuguese governor resides, contains 500 houses; it is situated at the mouth of a river which forms a small harbour, but it is not much visited. Porto Praya is a good harbour, and is visited by the vessels bound for India: it contains 1200 inhabitants.

S. Nicoló, the second island in extent, is 70 miles long, but narrow. It has more than 5000 inhabitants, who are very industrious, and make cotton-cloth, stockings, and tan goat-skins. It has a small town of the same name.

The other islands are Mayo, Fogo, Brava or S. João, Bona Vista, S. Lucia, S. Vincente, and S. Antonio.

These islands were discovered, in 1489, by the Portuguese under the conduct of Antonio de Noli, a Genoese in the service of Prince Henry, and some years afterwards they were settled. They are still in the possession of the Portuguese, and under a separate governor. Besides the few articles (goat-skins, salt, turtles, fruits, saltpetre, cattle, and asses) which are sent to Europe, the inhabitants have some commerce with the continent of Africa, where they sell cotton cloth.

In the sea which divide this group from Africa, the atmosphere for the greatest part of the year, is hazy and foggy, especially near the continent, so that the vessels sailing south prefer to keep to the west of the islands. The same phenomenon of a foggy atmosphere is observed farther north, between the Canaries and the coast north of Cape Bojador.

CAPELLA, or *Auriga*, a star of the first magnitude, in the body of the goat which Auriga is represented as carrying. [AURIGA.] This is a double star, with a small proper motion 0^h 13 in right ascension, — 0^h 35 in declination.

CAPERCAILLE, CAPERKALLY, or CAPERGALE, the Scotch name for the capercail or wood-grouse, now no longer holding a place in the British Fauna, of which it was one of the greatest ornaments.

Pennant refers this bird to the *Coc de Bois ou Puisin Bruyant* of Belon, and the *Gallo Cedrone* of the Italians; and it is very probable that these and other names; viz., *Gallo di Monte*, *Gallo Selvatico*, *Gallo Alpestre*, *Fusca Negro*, and *Fusiano Alpestre*, were applied both to the capercail and the black-cock, according to the different localities where the species occurred. [BLACK-CHICK.] Part of Belon's description of his *Coc de Bois*—such, for example, as the plume 'si noire et resplendant au-dessous du col, et do

l'estomach, qu'elle montre en ostre toute changoante,' and the tail with the feathers 'voultecs, c'est à dire courbeés en arc, et larges par le bout; ayant quelque petites, madures blanches,' might apply to the black-cock, while 'the size approaching to that of the peacock,'—the head not less than that of a bustard, with the great massive trenchant beak,—are much more applicable to the capercaillie, which is *Le grand Coq de Bruyères* of Brisson, the *Coq de Bruyère* ou *Tétrao* of Buffon, *Kjader* of the Fauna Suecica, *Tjader-hona* of Hasselquist, the *Tetrao Aurchan* of Temminck, *Auer Hahn* of Frisch, *Auerwaldhuhn* of Bechstein, the *Peacock of the Wood* (*Pavo Sylvestris*) of Gnauldus Cambrensis, *Capricolca* of Sibbald, the *Cock of the Mountain or Wood* (called by the Venetians *Gallo di Montagna*) of Willughby, the *Cock of the Wood or Mountain* of Ray, *Wood or Great Grouse* of Pennant, *Ceillog coed* of the ancient British, *Urogallus seu Tetras Major* of Aldrovand, *Tetrao Urogallus* of Linnaeus, and *Urogallus Vulgaris* of Fleming.

Geographical Distribution.—Temminck says that it is numerous in the north of Asia, and in Russia towards Siberia; and that it is common in Livonia, sufficiently abundant in Germany, in Hungary, and in certain parts of the Archipelago; he adds that it is more rare in France, and never found in Holland. Pennant states that these birds are common to Scandinavia, Germany, France, Italy, and several parts of the Alps. It is added in a note, on the authority of Hasselquist, that the bird was shot in the Isle of Milo on a palm-tree, and, on that of Belon, that it is found in Crete; and it is observed that the English translator of Hasselquist gives a false name to it, calling it *Black Game*. Mr. Lloyd says that it is to be found in most parts of the Scandinavian peninsula; indeed as far to the north as the pine-tree flourishes, which is very near to the North Cape itself. He adds that the bird is very rare in the more southern of the Swedish provinces.

That it was once frequent in the British islands there is no doubt, though it is now utterly extinct as a wild British species. Ray says 'Anglia hunc non habet. In Hibernia inveniri dicitur.' Pennant writes—'This species is found in no other part of Great Britain than the Highlands of Scotland, north of Inverness, and is very rare even in those parts.' It is there known by the name of *Capercaillie*, *Auer-cailze*, and in the old law books *Caperkally*—the last signifying the horse of the woods—this species being, in comparison of others of the genus, pre-eminently large. He also says—'In our country I have seen one specimen, a male, killed in the woods of Mr. Chisholme, to the north of Inverness. About the year 1760 a few were to be found about Thomas Town in the county of Tipperary, but I suspect that the breed is now extinct in every part of Ireland.' Graves (1813) says—'This species is nearly extinct in Great Britain: two instances of its being killed in Scotland within these few years are the only satisfactory accounts we have received of its being recently found in these kingdoms. One was killed by a gentleman of the name of Henderson near Fort William about six years ago, and sent to Dundee; but the vessel that conveyed it to London was detained so long on the passage that the bird became so putrid that only the head and legs could be preserved. The other specimen was shot by Captain Stanton near Burrowstoness two winters ago: they were both males. Some few are said to be yet remaining in the pine forests of Scotland, and also in the mountainous parts of Ireland.' Bewick speaks of it as very rare in Great Britain. In the last edition of Montagu (1833) it is stated that the bird was last seen in 1760 in the woods of Strathglass, that it continued in Strathpey till 1745, and that recent attempts have been made to re-introduce it from Norway without success. Selby (1825) alludes to its extirpation, and omits the species. Jeryns (1835) observes that it was formerly abundant in the mountainous forests of Scotland and Ireland, but that it is now extirpated.* A living pair came into the possession of the Zoological Society of London, but they did not long survive the loss of liberty.

We agree with Mr. Lloyd that it is a pity more attempts are not made to re-introduce this noble species, especially in Scotland, as a locality, as he observes, not very dissimilar to the south of Sweden—especially now that the pine so much abounds there, from which trees when the ground is covered with snow the capercaillies obtain nearly their whole sustenance. He adds that it is true a pair once in a while have

been brought over to this country from Scandinavia, though from some cause or other, and none more likely than over and improper feeding, these have soon perished. The experiment, as he says, should be made with a greater number of birds, and they should be entrusted to a person fully conversant with their habits. They are often domesticated in Sweden, and at both Uddeholm and Risäter Mr. Lloyd knew that they were kept for a long period in aviaries for the purpose. These were so perfectly tame as to feed out of the hand. Their food principally consisted of oats and the leaves of the Scotch fir (*Pinus sylvestris*), large branches of which were usually introduced into their cages once or more in the course of the week; they were also supplied with abundance of native berries when procurable. They were amply provided at all times with water and sand; the latter of which was of a rather coarse quality, and both were changed pretty frequently. The same author observes that it is a mistake that the capercaillie will not breed in a state of domestication; and as we are not without hope that some spirited proprietors—and Scotland has many such—may follow the example of the Earl of Fife, and endeavour to restore the bird to our Fauna, we insert the following anecdotes and directions to stimulate and guide those who may be inclined to try their fortune:—

'A few years ago,' writes Mr. Lloyd in his interesting *Field Sports*, 'I procured a brace of these birds, consisting of cock and hen, for a friend of mine, Mr. Thomas Powell Buxton, the member for Weymouth, then resident at Cromer Hall in Norfolk. After a lapse of a few months the hen laid six eggs, and from these, in process of time, six capercaillies were produced. The chicks lived until they had attained to a very considerable size, when, owing to the effects, as it was supposed, of a burning sun, to which they had been incautiously exposed, the whole of them, together with the mother, died. On this mishap the old cock, the only survivor, was turned loose into the game preserves, where he remained in a thriving condition at a year half. At last, met I, though this was supposed to be owing rather to accident than natural causes.'

In further corroboration of the fact that the capercaillie will breed when in confinement, we give the following quotation from Mr. Nilsson's work. That gentleman's authority was the former director of Uppsala; and the birds alluded to were at a forge in the province of Dalecarlia:—

'They were kept together during the winter in a large loft over a barn, and were fed with corn, and got occasionally a change of fresh spruce fir, pine, and juniper sprigs. Early in the spring they were let out into an enclosure near the house, protected by a high and close fence, in which were several firs and pines, the common trees of the place. In this enclosure they were never disturbed; and during the sitting season no one approached except the person who laid in the meat, which at that time consisted of barley, besides fresh sprigs of the kinds before mentioned. It is an indispensable rule that they shall have full liberty, and remain entirely undisturbed, if the hens are to sit and hatch their young. As soon as this had occurred, and the brood were out, they were removed to the yard, which was also roomy, and so closely fenced that the young ones could not escape through; and within this fence were hedges and a number of bushes planted. Of the old ones one of the wings was always clipped, to prevent their flying. I have seen several times such broods, both of black game and capercaillie, eight to twelve young ones belonging to each hen. They were so tame that, like our common hens, they would run forward when corn was thrown to them. They should always have a good supply of sand and fresh water.'

Mr. Greiff gives the following directions for rearing the young:

'The eggs,* usually so called, to be found in ant hills and stubble, are to be gathered; hard boiled eggs are to be chopped and mixed amongst fine moistened barley meal; also pea-haulm and trefoil-grass are to be given them for food, and water to drink, which must be placed so that they cannot overturn the pitcher, for they suffer very much if they get wet when they are young. Dry sand and mould they never should be without. When they get larger, and cabbage-leaves, strawberries, cranberries, and blueberries are to be had, they are fond of such food; and when they are full grown they eat barley and wheat; and in winter

they should get young shoots of pine and birch-buds. I have seen many people who thought they treated young birds well by giving them juniper berries; but they never resort to this kind of food but in case of necessity.

The following observations of Professor Nilsson show how well this bird is adapted for the game preserve.

'When the capercaillie is reared from the time of being a chicken, he frequently becomes as tame as a domestic fowl, and may be safely left by himself. He, however, seldom loses his natural boldness, and, like the turkey-cock, will often fly at and peck people. He never becomes so tame and familiar as the black-cock. Even in his wild state the capercaillie frequently forgets his inherent shyness, and will attack people when approaching his place of resort. Mr. Alderberg mentions such an occurrence. During a number of years, an old capercaillie had been in the habit of frequenting the estate of Villinge at Wermdö, who, as often as he heard the voice of people in the adjoining wood, had the boldness to station himself on the ground, and, during a continual flapping of his wings, pecked at the legs and feet of those that disturbed his domain.'

For the details of the experiment made by Lord Fife in the years 1828, 1829, 1830, and 1831, we must refer the reader to Mr. Wilson's interesting paper in 'Jameson's Journal' for July, 1832. Suffice it to say that, after some failures, Mr. Wilson, in August, 1831, s. at Braemar five young capercaillies, which had been hatched there, and were, with their parents, in good health. The intention of the Thane was, 'as soon as some healthy broods had been reared in confinement, to liberate a few in the old pine woods of Braemar, and thus eventually to stock with the finest of feathered game the noblest of Scottish forests.'

Food.—Temminck makes it to consist of many sorts of berries, the buds and young shoots of the leaves of trees and of Alpine shrubs; also of insects, but rarely of seeds. Mr. Lloyd says that it feeds principally on the leaves of the Scotch fir (Tal), and very rarely on those of the spruce (Gran); also on juniper berries, cranberries, blueberries, and others common to the northern forests, and occasionally in the winter time on the buds of the birch &c. The young, he says, are, for the most part, sustained at first on ants, worms, insects, &c.

Reproduction.—Temminck says that the nest is formed in high herbage and under bushes, and that the hen lays from six to sixteen obtuse eggs of a dirty white colour, marked with yellowish spots. Latham states that he is well informed that the nest of one found in Scotland was placed on a Scotch pine: 'if so,' says Montagu, 'it differs from all the genus, who are known to lay their eggs on the bare ground.' Mr. Lloyd, who had the best opportunities for ascertaining the fact, observes that the hen makes her nest upon the ground, and lays from six to twelve eggs, and that her young keep with her till towards the approach of winter; but that the cock separates from the mother before the hens. The same author describes, evidently from personal observation, the *lek* or play of the male in the breeding season, and, in itself most interesting, and corrects some errors which have gone abroad on the subject, we make no apology for inserting it.

'At this period, and often when the ground is still deeply covered with snow, the cock stations himself on a pine, and commences his love-song, or *play* as it is termed in Sweden, to attract the hens about him. This is usually from the first dawn of day to sunrise, or from a little after sunset until it is quite dark. The time, however, more or less, depends upon the mildness of the weather, and the advanced state of the season.

'During his play the neck of the capercaillie is stretched out, his tail is spread and spread like a fan, his wings droop, his feathers are ruffled up, and in short, he much resembles in appearance an angry turkey-cock. He begins his play with a call something resembling *Peller, peller, peller*; these sounds he repeats at first at some little intervals; but as he proceeds they increase in rapidity until at last, and after perhaps the lapse of a minute or so, he makes a sort of gulp in his throat, and finishes with sucking in, as it were, his breath.

'During the continuance of this latter process, which only lasts a few seconds, the head of the capercaillie is thrown up, his eyes are partially closed, and his whole appearance would denote that he is worked up into an agony of passion. At this time his faculties are much absorbed, and it is not

difficult to approach him; many, indeed, and among the rest Mr. Nilsson, assert that the capercaillie can then neither see nor hear: and that he is not aware of the report or flash of a gun, even if fired immediately near to him. To this assertion I cannot agree, for though it is true that if the capercaillie has not been much disturbed previously he is not easily frightened during the last notes, if so it may be termed, of his play; should the contrary be the case, constantly on the watch, and I have reason to know that, even at that time, if noise be made, or that a person exposes himself incautiously, he takes alarm and immediately flies.

'The play of the capercaillie is not loud, and should there be wind stirring in the trees at the time, it cannot be heard at any considerable distance. Indeed, during the calmest and most favourable weather, it is not audible at more than two or three hundred paces.

'On hearing the call of the cock, the hens, whose cry in some degree resembles the croak of the raven, or rather, perhaps, the sounds *Gock, gock, gock*, assemble from all parts of the surrounding forest. The male bird now descends from the eminence on which he was perched to the ground, where he and his female friends join company. The capercaillie does not play indiscriminately over the forest, but he has his certain stations (*Tjador-lek*, which may perhaps be rendered his playing grounds.) These, however, are often of some little extent. Here, unless very much persecuted, the song of these birds may be heard in the spring for years together. The capercaillie does not during his play confine himself to any particular tree, as Mr. Nilsson asserts to be the case, for, on the contrary, it is seldom he is to be met with exactly on the same spot for two days in succession.

'On these *lek* several capercaillie may occasionally be heard playing at the same time; Mr. Greiff, in his quaint way, observes, "it then goes gloriously." But so long as the old male birds are alive they will not, it is said, permit the young ones or those of the preceding season to play. Should the old birds, however, be killed, the young ones, in the course of a day or two, usually open their pipes. Combats, as it may be supposed, not unfrequently take place on these occasions, though I do not recollect having heard of more than two of those birds being engaged at the same time.

'Though altogether contrary to law, it is now that the greatest slaughter is committed among the capercaillie; for any lurch of a fellow who has strength to draw a trigger man, with a little instruction, manage to knock them down. But as the plan of shooting these noble birds during their play is something curious, I shall do my best to describe it.

'It being first ascertained where the *lek* is situated, which is commonly known to the peasants and others in the vicinity, the sportsman (if so he may be called) proceeds to the spot, and listens in profound silence until he hears the call of the cock. So long, however, as the bird only repeats his commencing sound, he must, if he be at all near to him, remain stationary; but the instant the capercaillie comes to the wind-up, the gulp, &c., during which, as I have said, his faculties of both seeing and hearing are in a degree absorbed, then he may advance a little. But this note lasts so short a time that the sportsman is seldom able to take more than three or four steps before it ceases, for the instant that is the case he must again halt, and, if in an exposed situation, remain fixed like a statue. This is absolutely necessary, for during his play, excepting when making the gulp, &c., the capercaillie is exceedingly watchful, and easily takes the alarm. If all remain quiet, the bird usually goes on again immediately with his first strain; and when he once more comes to the final note, the sportsman advances as before, and soon, until he gets within range of shot.

'To become a proficient at this sport requires a good deal of practice. In the first place, a person must know how to take advantage of the ground when advancing upon the capercaillie, for, if full daylight, this is hardly practicable (what ever may be said to the contrary) in exposed situations; and in the next, that he may not move forward, excepting upon the note which is so fatal to that bird. This is likely enough to happen, if it be an old cock that has been previously exposed to shots, for he often runs on, as I have repeatedly heard him, with *Peller, peller, peller*, until one supposes he is just coming to the gulp, when he suddenly

make a full stop. If, therefore, a person was then incautiously to advance he would in all probability instantly take to flight.

At the *lek*, the cocks most commonly fall the sacrifice; for the hens, as well from their colour more resembling the foliage of the trees, as from the sportsman having larger and better game in view, usually escape. This is a fortunate circumstance; as were a proportionate slaughter to take place among the latter as the former, the breed in many parts of the Scandinavian peninsula would soon be exterminated.

In following this amusement, accidents have occurred. In the gloom of the morning or evening, it has happened that whilst a person has been stealing silently forward among the trees, he has been taken by others engaged in the same pursuit for a wild beast, and in consequence a ball has been sent whistling after him. I heard of one man who in this manner was shot through the body.

The number of capercaillie a man may shoot in a given period by the above means, depends altogether upon circumstances. Indeed it often happens that in countries abounding with these birds, from the state of the weather, there being a crust upon the snow, &c., the most experienced chassecurs will hardly kill a single one for days together. I have however heard people assert they have bagged as many as six or seven in the course of the morning and evening of the same day: but one or two is a much more usual number. A peasant in the interior, who devotes a good deal of time to the purpose, will, if he understand what he is about, commonly kill from fifteen to twenty; and in one instance I remember hearing of twenty-nine in the course of the season. This, in a country where every one carries a gun, will give an idea of the havoc that is made among the capercaillie, and readily explains their present (as I contend) scarcity.

Though this plan of shooting the capercaillie during the spring is common throughout most parts of Scandinavia, I am told, that in Norrland and Wästerbotten, from whence Stockholm is furnished with its principal supplies of game, that destructive practice is not generally adopted. This arises from the people in those districts having sense enough to know, that if they kill too many of the cocks in the spring, there is little probability of there being a good breed during the succeeding autumn.

The capercaillie occasionally strikes up a few notes, in the manner of which I have spoken, during the autumnal months,—about Michaelmas, I believe. For this it is perhaps difficult to assign a reason. Mr. Greff suggests "that it may be to show the young birds where the *lek* is situated." I have never myself heard the capercaillie playing at this period of the year; but I have met with men, on whose word I am inclined to place confidence, who have repeatedly killed them at that time whilst so occupied.

Though so many of these magnificent birds are destroyed by the unsportsmanlike means which I have just described, it rarely happens that more than one of them is killed at a shot; indeed I never heard of but a solitary instance, where as many as three were destroyed at a single discharge. This I am aware is a little at variance with the statement of other Scandinavian travellers: one among them says, "In that season (the spring) the peasant, at an early hour of the morning sallies forth into the forest, armed with his fowling-piece, and listens attentively for the voice of the cock, which, perched on a lofty pine, brings the hens together from all parts; the other cocks likewise repair to the spot, and, incited by love and jealousy, a furious battle commences, during which they are so deeply engaged, and so inattentive to their own safety, that the gunner will frequently kill no less than a dozen of these large birds at a shot." Of course it is not for me to contradict this statement, though, independently of its not being usual for the capercaillie to engage in such battles royal as are here described, it would seem to require a gun of no ordinary calibre to slaughter at a single discharge a dozen birds, each of which is pretty nearly as large as a turkey-cock.

The traveller to whom I have just alluded, in speaking of the capercaillie, in another part of his work says, "The difficulty of finding their eggs is so great, that the peasants even seem to consider it in a manner proverbial; and I never met with one of them who had either seen the same or discovered a nest." This may be the case, for all I know to the contrary, in other parts of Scandinavia; but in Wermeland and the adjacent provinces, at all events, it was no

unusual occurrence for people to fall in with both one and the other.

The same author, in describing the play of the capercaillie, has, I apprehend, committed a mistake, for he says, "His note, though extremely varied during the breeding season, consists principally of an extremely loud hissing kind of cooing, which may be heard for a considerable distance around." Now, this description, which would not unaptly apply to the black-cock, is certainly as opposite as light is from darkness to the play of the capercaillie.

Chace.—Our limits will not permit us to enter into the details of the more legitimate chace, which will be found in Mr. Lloyd's book: suffice it to say that the rifle is the instrument used by the fair sportsman, and that, in the course of his sport, Mr. Lloyd observed that when the weather is cold, and the snow loose and soft, the capercaillie not unfrequently buries himself beneath its surface during the night season, and once in a while he found the bird in that situation in the day-time: so that the old wood-cuts of grouse nesting under the snow are not entirely without foundation. Mr. Lloyd remarks that the capercaillie often becomes the prey of the great horned owl. [BONO.]

Utility to man.—As an article of food the capercaillie is justly admired; and the rapidity of communication consequent upon the increased and increasing development of the powers of steam, now furnishes annually the shops of the London poulterers with a supply in the spring. Some assert that at certain seasons the flavour of the bird is rendered extremely unpleasant by the fir buds which then form its food; but those which we have tasted were excellent. The hen, though smaller, is in our opinion preferable to the cock. In preparing the bird for roasting, the breast should be skinned and a veal caul spread over it.

Description.—*Male.*—Elongated feathers of the throat black; the rest of the head and neck ashy black; eyebrows red; wings and scapulars brown, sprinkled with small black dots; breast changeable green; belly and abdomen black; with white spots; rump and flanks sprinkled with ashy zigzags on a black ground; tail feathers black, with some small white spots disposed at about two inches from their extreme tips. Bill nearly three inches long, very strong, hooked, and of a whitish horn colour; iris clear brown; length about 2 feet 10 inches: usual weight from 9 to 12 lbs. Graves says that the fine specimen from which his figure was taken measured feet 1½ inch in length, 7 feet 3 inches in breadth and 15 lbs. 2½ ounces.

Female.—Iris spotted with red or bay, black and rather of the head bright ruddy, and those of the bill black; tail ruddy, striped with black; bill blackish brown: size about one-third less than that of the male.

Young males, after their first moult.—Breast of a less lustrous green than in the old birds, and the ash-colour predominating over the black; some red feathers spotted with black are scattered irregularly over the plumage. Before the first moult the young males resemble the females.

N. B. There are some anatomical differences between the form and extent of the trachea of the male and that of female.

HYBRIDS.

Mr. Lloyd says that the capercaillie occasionally breed with the black game; the produce of which are in Sweden called Räcklehanen: these partake of the leading characters of both species; but their size and colour greatly depend upon whether the connexion was between the capercaillie cock and the grey hen, or *vice versa*. 'Out of twenty räcklehanar, which is the male, two, according to Mr. Falk, are not alike; and the difference of colour observable among the räcklehanar, which is the female, but very rare, is still greater. Räcklehanen are very seldom to be met with. During my stay in Wermeland, however, Mr. Falk had two of these birds in his possession, and I myself shot a third.' The bird here alluded to was probably the räckelhan (Tetrao medius of Moyer), which Temminck observes, some naturalists, and recently M. Nilsson, have erroneously considered a hybrid between the capercaillie and black cock. But at Braemar, in 1828, in consequence of the death of the hen which had been imported with a cock, a common barn-door hen was introduced to the latter. The result, according to Mr. Wilson, was, that she laid several eggs, which were placed under other hens; but from these eggs only a single bird was hatched, and when it was first observed it was

found lying dead. It was however an evident mule or hybrid, and showed such unequivocal marks of the capercali character as could not be mistaken.

[Tetrax Urogallus. Male.]

CAPERNAUM, an ancient city of Galilee in Palestine, about seventy miles N. by E. from Jerusalem. It is situated on the north-western shore of the Sea of Tiberias. It was a place of considerable importance in the time of Christ, who describes it as 'exalted unto heaven.' The place derives its chief interest from the manner in which it is mentioned in the New Testament. It was there that Jesus Christ commenced his public ministry; and in its neighbourhood he delivered the Sermon on the Mount. Its continued impenitency and unbelief, notwithstanding the peculiar opportunities with which it was favoured, led to the denunciations pronounced against it. No town now exists on the spot which is usually recognized as the Capernaum of Scripture. This place is now called *Tel-Houm*, *Tel-Hewen*, or *Tel-Houm*, according as travellers variously pronounce the Arabic name, near which the rivulet *El Eshe* empties itself into the Lake of Tiberias. The view of the lake from this place is peculiarly grand and impressive. Capernaum is now only a Bedouin station; but the former existence of a town of some importance is proved by fragments of buildings, hewn stones, and broken pottery, strewed to a considerable extent around. The foundations of a large and magnificent edifice may still be seen; but not enough of the building itself to determine whether it was a temple or a palace.

CAPET, HUGUES, the founder of the third, or, as it has been called from him, the *Capetian* dynasty of French princes, of whom little authentic information is preserved. The monks indeed speak of a vision which informed him that the translation of the bones of St. Riquier from Flanders to the confessor's own monastery at Centule, should be rewarded by the crown of France for himself, and its duration in his family till the seventh generation. His own great fief, as Count of Paris, gave him considerable predominance; and on the death of the last of the Carolingians, A.D. 987, Louis V. the Stolid (*Le Fainéant*), he successfully usurped the throne, and was confirmed in its seizure by the confederacy of turbulent barons, who yielding him as much obedience as it suited them, invested him with the nominal title of king. What remains to be told of Hugues Capet after his accession belongs entirely to general history. The origin of the name of the family has

been disputed, and indeed by some has been considered as given in ridicule; but the chroniclers in general affirm that he was a knight of ancient and noble extraction, and the imputation of plebeian birth which has been advanced against him is manifestly founded upon a misconstruction of a well-known line in the *Purgatory* of Dante, containing, in which that poet satirically makes the usurper declare of himself—'I was the son of a butcher of Paris.' The commentators explain this line by adding, that Hugues the Great, Count of Paris, the father of Hugues Capet, was a rigid executioner of the sentences which he had passed. M. de Sismondi, *Hist. des Français*, iv., 38, has shown that Velly is not to be trusted in his account of the family of Capet; but the reader may be safely referred to M. de Sismondi himself, to the Preface to the third volume of the great collection, generally known under the name of Bouquet, or to the *Preuves de la Généalogie de Hugues Capet in L'Art de vérifier les Dates*, v. 668.

A single anecdote may suffice to show the little authority which Hugues possessed over his vassals. 'Who has made you count?' was the inquiry which he directed a herald to put to Aldebert de Perigueux, who had assumed the title of Count of Poitiers and of Tours. 'And who has made you king?' was the only reply which Aldebert vouchsafed to return by the same messenger. As a supposed atonement for the illegitimacy of his accession, Hugues himself never wore the crown. Some have stated that, by abstaining from this bauble of royalty, he hoped to obtain the addition of one generation to those which had been prophesied to him. Both the dates of his usurpation and of his death are uncertain, but the former is usually fixed in A.D. 987; the latter A.D. 996. Thirteen kings (fourteen if we include John, who lived but eight days, and was never crowned) succeeded from his family; and it was not until 1328, that Philip VI. of Valois transferred the sceptre to his own most detestable race.

The family of Lorraine, which had been excluded by Hugues Capet when he put aside the right of Charles Duke of Lorraine, uncle of Louis V., proudly boasted of their Carolingian origin; and the party name Huguenot, which arose during the wars of the League, has sometimes been attributed to the attachment manifested by the reformed to the reigning king, the representative of Hugues Capet, in preference to the Gueses, who were derived from Charlemagne. On the accession of the line of Bourbon, the name was either adopted by them or given to them; and all the processes in the trial of the unfortunate Louis XVI. were directed against Louis Capet.

CAPERS, the young flower-buds of *Capparis spinosa*. [CAPPAIDACEÆ.]

CAPIAS. This term denotes in law certain writs so called from the occurrence of the word (*capias*) in the ancient Latin forms:—

1. *Capias ad respondendum*. This is a judicial writ by which all personal actions (that is, such as do not relate to land or real property) are commenced in the superior courts of common law against any person whom it is intended to arrest or hold to bail, and who is not already in custody.

Since the passing of the Uniformity of Process Act (2 Will. IV. c. 39), the force of the writ of *capias ad respondendum* therein prescribed is the same in all the courts; and it is also the actual commencement of the action. In form it is a command from the king to the sheriff, to take the defendant if he shall be found in his bailiwick, and him safely keep until he shall have given bail, or made a deposit according to law in a specified action, at the suit of the plaintiff, or until the defendant shall by other lawful means be discharged from custody. The sheriff is also required to deliver a copy of the writ to the defendant; and the defendant is enjoined to take notice that within eight days after the execution of it he must cause special bail to be put in for him in the court from which the writ is issued. The sheriff is also commanded to make his return to the writ immediately after he has executed it, stating the day of such execution; or if not executed within four calendar months from the date, then that he also return it, or sooner, if lawfully required to do so. It is witnessed in the name of the chief judge of the court from which it issues, and is dated on the day it issues.

2. *Capias ad satisfaciendum*, usually called *ca. sa*. This is a writ of execution to imprison the person of the defendant after judgment has been obtained against him,

until he make satisfaction to his creditor. It commands the sheriff to take the defendant, and him safely keep, so that he may have his body in court on the return of the writ to satisfy the plaintiff. This writ must strictly pursue the judgment upon which it is founded; that is, in a judgment against two persons, the *ca sa* cannot issue against one only, unless the other be dead; nor can it be sued out for a larger sum than has been recovered against the defendant.

Formerly it was the practice to *teste* (that is, date it) in Term time, but now it may be *tested* on the day on which it is issued (3 and 4 Will. IV. c. 67, s. 2). It may also by that act be made returnable immediately after the execution, instead of waiting until the ensuing Term, which was often productive of great loss and delay; nor is it now necessary that any certain number of days should elapse between the *teste* and the return. Where the sheriff can do so, he ought regularly to return, by indorsement on the back of the writ, the manner in which he has executed it; for instance, that he has either taken the defendant and has his body ready, or that the defendant is so ill that he cannot be moved, or that he is not to be found in his bailiwick; in which latter case another *capias*, called a *testatum capias*, may issue into another county; but it is not usual in practice for the sheriff to return the writ unless called upon to do so by a rule of court. The writs, when returned, are filed with the *custos brevium*, and a sheriff is answerable in damages to the plaintiff for making a false return.

Every writ of *ca sa* should be indorsed with the party's addition and residence, or such other description as the plaintiff may be enabled to give, together with the amount of the debt which the sheriff is to levy: the plaintiff at his peril indorses more.

The mode of executing this writ is generally the same as in the case of a writ of *capias ad respondendum*.

The effect of taking a party in execution upon a *ca sa* is, that it operates at once as a satisfaction of the debt, and no other writ of execution can be sued out upon the same judgment against the defendant's goods or lands, unless he die in confinement or escape from custody.

3. *Capias ad satisfaciendum* to *fix the bail*.—Where bail have been given in the original action, they stipulate in this triple alternative, that the defendant should, if condemned in the suit, satisfy the plaintiff his debt and costs; or that he should surrender himself a prisoner, or that they should pay the debt for him. [BAIL.] Where therefore the defendant is at large after the judgment, and the bail are responsible, it is often of importance to fix them with the debt; for this purpose a *ca sa* must first be sued out against the principal, upon which the sheriff must return that he is not to be found, for the bail are not bound to render their principal until they know by the plaintiff's suing out this writ, that he means to proceed against the person of the defendant and not against his goods [EXECUTION]; and for the purpose of affording the bail this information, the writ must lie in the sheriff's office four clear days before the return, and be entered in a book kept for that purpose. It must be directed to the sheriff of the county where the action was tried. The sheriff returns that the defendant is not to be found as a matter of course, without even attempting to take him (except where he is actually in his custody) as the *ca sa* is merely intended as a notice to the bail of the plaintiff's intention to proceed against them; and if they do not render their principal in time, the plaintiff may proceed for the debt against the bail.

4. *Capias utlagatum* is a writ that lies against a person who has been outlawed in any action. It is either general or special; the former against the person only, the latter against the person, lands, and goods. (Stat. 2 W. IV., c. 39, s. 6.) [OUTLAWRY.]

5. *Capias pro fine*, the name of an ancient writ now obsolete, by which the defendant who had judgment given against him might in some cases be arrested for his wilful delay of justice until he paid a fine to the king for the same.

6. *Capias in withernam* was a writ, now obsolete, which lay where a distress taken was driven out of the county, so that the sheriff of that county could not deliver them to the party applying to have them replevied. [DISTRRESS, REPLEVIN.]

(*Index's Practice*; *Index*, tit. *Capias*; *Archbold's Practice* by Chitty.)

CAPILLARY (SARNEYA.)

CAPILLARY ATTRACTION and REPULSION. These names have been given to the properties of matter

which cause the ascent or descent above or below the level of the surrounding fluid which takes place when a tube of very small diameter (like a hair, *capillus*) is dipped into water, mercury, &c. This phenomenon, which excited early remark from its peculiarity and apparent exception to all the laws which regulate the equilibrium of fluids, has given its name to what is rapidly becoming an extensive and well connected theory of the action of the parts of solids and fluids upon each other. We shall however in this article confine ourselves to the description of phenomena which are strictly capillary, in the original sense of the word, referring to MOLECULAR ATTRACTION for an account of the general theory which explains these phenomena as particular cases of a more extensive class. Our reasons are, 1. The improper use of language which exists in comprehending so extensive a range of phenomena as are contained in the theory in question, under a term which is derived from a very limited and special class of experiments: 2. Our general plan of confining articles on questions of physics to the leading points connected with the name at the head of the article: 3. The consideration that the whole of this theory is in a state of such apparent progression that a very short time may materially increase its extent.

That solid substances, either directly or by means of some interposed agent [ATTRACTION], attract each other, or endeavour to produce motion in each other, has been abundantly demonstrated both by celestial and terrestrial phenomena. That the parts of solids exercise force on each other is evident from the force which is required to separate them. [COHESION.] That the parts of liquids exercise a feeble action of the same kind is also sufficiently obvious. And the common property of most fluids with respect to solids, namely, that the former wet the latter, is proof of a similar connection between solids and fluids. If glass be dipped into water and then drawn out, a portion of the fluid is drawn out with it, some of which hangs from the bottom of the glass. Here is sufficient proof of a force which overcomes the weight of the fluid; whatever may be its cause or mode of action, there is an attraction of the particles of the water to those of the glass; but the every-day character of the phenomenon did not excite much attention until the appearance of the same kind of effect in a peculiar form, namely, that of capillary attraction, made the experiment a philosophical one.

The preceding diagram represents the appearance (in section) of a fluid into which a tube of very small diameter is plunged enlarged for the sake of distinctness. The fluid either rises or sinks in the tube above or below the level of the exterior; and at the same time is slightly curved at what would be, were it not for this curvature, the exterior level immediately adjoining the tube. It is also to be observed that in cases where the fluid stands higher within the tube than without, its upper surface is always concave; but that when the fluid is lower within the tube, it is convex: both appearances are represented in the diagrams. When the solid is one which can be wetted by the fluid, the elevation and concavity are observed; but when the solid appears to repel the fluid, the depression and convexity are observed. Glass and water furnish an instance of the first; glass and mercury of the second. Thus the bulbous appearance of the top of the mercury in a barometer is a phenomenon of the kind represented in the second diagram [BAROMETER]. The different appearances presented by water and mercury with respect to glass may be thus stated. A drop of water upon a level piece of glass becomes hemispherical or nearly so, and adheres; a very small drop of mercury retains its spherical form, and rolls easily. It is not true that the glass actually repels the mercury; M. Gay-Lussac found that a disc of glass of 120 millimetres (4 inches 7 tenths) in diameter required a separating force of from 150 to 300 grammes (a pound avoirdupois is 453½ grammes) to detach it from the surface of

a bath of mercury. The inference is that the attraction of the particles of mercury upon mercury is stronger than that of the particles of glass upon mercury, but that the action of glass upon water is stronger than that of water upon water.

The laws according to which the fluid rises or falls have been experimentally determined, and are also found to be deductions from the theory which has been proposed for their explanation. They are as follows:—1. The action of the fluid or solid, of what kind soever it may be, is sensible for a very small extent only: thus a tube of dry glass, and the same tube previously wetted throughout its whole interior with the fluid to be examined, cause different amounts of elevation. In the first case, when the equilibrium is established, the particles in immediate connection with the top of the concavity are of glass: in the second case they are of water, and we are in fact immersing a small tube of water into water, the glass being merely an outer case, on which the water is deposited. The action of the glass appears not to extend the depth of the thin film of water which comes into immediate contact with the water from the vessel. And it is found that whatever the substance may be which serves as a case for the film, the elevation is the same. 2. When cylindrical tubes of different diameters are compared, the elevation is inversely proportional to the diameter: namely, that in a glass tube of $\frac{1}{100}$ of an inch in diameter water stands twice as high as in one of $\frac{1}{20}$ of an inch; and so on. According to the experiments of M. Gay-Lussac, a wet tube of one millimetre in diameter causes an elevation of 29.79 millimetres of water; and a tube of glass of two millimetres in diameter causes a depression in mercury of 4.58 millimetres. 3. Whatever the form of the tube may be, the elevation or depression is found to depend only upon the diameter at the upper part of the elevation, in this manner, for instance; if a small conical tube widening downwards be dipped into a fluid which is found to rise in it to an elevation at which the tube has a diameter of $\frac{1}{10}$ of an inch, then if a cylindrical tube of $\frac{1}{10}$ of an inch were immersed in the same fluid, the water would rise to the same height as in the conical tube. 4. If the tube be double (one tube within another) the fluid rises to the same height in the interval between the two tubes, as it would do in a tube with that interval for its radius. 5. Between two parallel plates immersed at a very small interval the fluid rises as high as in a tube with that interval for its radius. 6. Between two plates vertically placed, but inclined at a very small angle (like a double screen nearly closed) the fluid rises higher and higher as we proceed towards the upright line of junction: and the curve of the upper surface of the fluid is an hyperbola. Assuming the principle rendered probable in (1), namely the extreme smallness of the extent to which molecular forces act sensibly, all the remaining facts are deductions from theory as well as results of experiment.

We shall not give a table of the results obtained by different experimenters, because they vary considerably as to amount, though in the results of the same observer, the fact marked (2) in the preceding list generally appears very near the truth. The discrepancy possibly arises from the various degrees of internal moisture in the tubes. Experiments have been made from the time of Newton, but it is only since the application of the molecular theory by Laplace that it seems to have been always admitted and acted upon, that the internal coating of the tube immediately adjacent to the fluid is the cause of the phenomenon. The results of various observers upon glass and water give elevations of from two to five inches in a tube of one-hundredth of an inch: the result of M. Gay-Lussac (who always observed with moistened tubes, and found all his experiments agree very nearly with each other) gives an elevation of 4.62 inches for the same diameter. The elevations of fluids vary also with the temperature, the former diminishing as the latter increases.

We shall conclude this article with considerations which may give readers who cannot study the mathematical theory a notion of the manner in which the phenomena may be supposed to arise, referring to MOLECULAR ATTRACTION for some account of the different modifications which the theory has undergone. But, as it must add materially to the interest which attaches to any theoretical description, to know how far the results coincide with experiment, we shall cite the following from a very complete account of the progress of investigation on this subject, the 'Report on the Theory of Capillary Attraction,' by Professor Challis, *Rep. Brit.*

Ass. for 1831, p. 253. From observations of the elevation of water, alcohol, and oil of turpentine, in tubes of white glass, the forces necessary to elevate a disc of the same substance, 118.366 millimetres in diameter were ~~theoretically~~ deduced, and found to be 59.59, 31.14, and 34.35 grammes for the three fluids. Experiment determined the same forces to be 59.40, 31.08, and 34.10 grammes.

The tube being immersed in the fluid, of which the natural level is AB, let us consider a small canal of fluid C D E F B. The glass immediately above C exercises an uncompensated attraction on the fluid; but at any point X between C and D, the action of the glass is equal upwards and downwards, so that there is no further disturbance till we come to D, where the side of the canal ceases to be of glass, and becomes of fluid. There is then at D the difference of the actions of the glass and fluid, *downwards*, if the action of fluid on fluid be the stronger; *upwards*, if that of glass on fluid be the stronger. We suppose the actions to extend to very small distances only. But the counterpoising column B F is in its natural state. If then twice the action of the glass on the fluid (namely those exerted at C and D) exceeds that of the fluid on the fluid at D, a part of the weight of the column C D is counterbalanced by the excess of upward pressure, and this column, so relieved, cannot counterbalance the weight of B F, unless its length is so increased that the excess of length may counterpoise the upward pressure. The fluid immediately adjoining the side will therefore rise, and the same all round the interior of the tube. But so long as the cohesive quality of the fluid exists, the fluid still more in the interior of the tube will also rise, and this will continue until the whole body of fluid raised is a counterpoise to the inequality of the actions. Similarly, if the action of the fluid at D exceed those of the glass at C and D, there will be a downward pressure equivalent to an increase of weight in the column C D. That column therefore will fall, and with it the columns still more in the interior. This explanation, though exceedingly imperfect, will serve to give the first notion on the subject: and the following experiment tends to confirm it. If the tube be filled with fluid, and then held vertically with the lower opening stopped by the finger, which is then gently removed, some of the fluid will drop out, but a column will remain suspended in the tube, ended by a hanging drop from the lower extremity. And it is always found that the length of this column is considerably greater than the elevation when the tube is immersed in the fluid: in fact, the action of the fluid below D on the right is now removed, or a pressure downwards is removed, consequently a longer column is required to counterbalance the actions of the glass at C' and D.

In consequence of the minuteness of the tubes which are required to produce sensible effects, very few can actually make experiments on this subject for their own instruction. But a lump of white sugar or a fine sponge, either of which is a collection of minute tubes, held with the lower end slightly immersed, will immediately cause an ascent of the fluid.

The elevation of the fluid being always accompanied by convexity, and the depression by concavity, a word of words prevails in philosophical treatises which is extremely embarrassing to the learner. It is said the concavity causes the elevation, and the convexity the depression. It is true that when two phenomena always appear together, and one being given the other may be found, either may be treated mathematically as the cause of the other. But this doctrine of mathematical causes [Attraction] is inconvenient to all but mathematicians; when, as in the present case, there is a physical agent of a different kind certainly present. With a warning, however, as to the use of the

word cause thus introduced, the inconvenience may be diminished or altogether destroyed.

CAPILLARY VESSELS, so called from their hair-like minuteness. The blood-vessels of the body consist of arteries and veins, the arteries carrying blood from the heart, and the veins returning it to the heart. It has been shown (ARTERY) that the arterial system is arborescent, that is, that the branches which spring from the aorta successively increase in number and diminish in size as they proceed from the heart towards their ultimate terminations in the system. These ultimate terminations of the arteries, together with the first origins of the veins, constitute a peculiar system of vessels termed the *capillary system*. These capillary vessels are too minute to be detected by the naked eye; but in the transparent parts of the body of a living animal, when brought under the field of the microscope, they become perfectly visible, as in the web of the frog's foot and the mesentery of the rabbit. The greater number of the arteries and veins are then seen to be directly continuous with each other, no substance intervening between the two orders of vessels. No words can describe the beauty of the sight presented by the flow of the vital fluid through these minute tubes. Myriads of vessels not visible to the naked eye instantly come into view. In one case the direction of a minute artery being suddenly altered it is reflected on itself, and thus becomes an incipient vein; in other cases minute branches are sent off from an artery into a parallel vein; and in a third case several minute arterial ramifications are continuous with a single vein. The venous capillaries are generally larger and more numerous than the arterial, and they communicate more freely with each other.

The minute capillary vessels are totally distinct both in structure and office from the large trunks from which they spring. All the tunics of the capillary arteries diminish in thickness and strength as the tubes lessen in size, but more especially the middle or fibrous coat [ARTERY], 'but this coat may still be distinguished by its colour in the transverse section of any artery whose internal diameter is not less than the tenth of a line: but it entirely disappears in vessels too small and too remote to receive the wave of blood in a manifest jet. But while the membranous tunics diminish, the nervous filaments distributed to them increase. The smaller and thinner the capillary the greater the proportionate quantity of its nervous matter; and this is most manifest in organs of the greatest irritability. The coats of the capillaries successively becoming thinner and thinner at length disappear altogether, and the vessels ultimately terminate in membraneless canals formed in the substance of the tissues.'

Of the capillary arteries which it has been stated terminate by direct communication with the capillary veins, 'some are large enough to admit of three or four of the red particles of the blood [BLOOD] abreast; the diameter of others is sufficient to admit only of one; while others are so small that they can transmit nothing but the serum of the blood. As long as the capillary is of sufficient magnitude to receive three or four particles abreast, it is evident that it possesses regular parietes; but by far the greater number before they communicate with veins lose altogether their membranous coats. There are no visible openings or pores in the sides or ends of the capillaries by means of which the blood can be extravasated preparatory to its being imbibed by the veins. There is nowhere apparent a sudden passage of the arterial into the venous stream, no abrupt boundary between the division of the two systems. The arterial streamlet winds through long routes, and describes numerous turns before it assumes the nature and takes the direction of a venous streamlet. The ultimate capillary rarely passes from a large arterial into a large venous branch.'

All the great organic functions of the living body are performed mainly by the capillary arteries. Their action is essential to secretion, nutrition, calorification, and every other process which is indispensable to the support of life. Accordingly it is found by direct experiment that these vessels possess an active contractile power altogether independent of the impulse derived from the heart. Under the ordinary condition of the circulation, the blood indeed flows through these capillary vessels by the force communicated to the circulating fluid by the contraction of the heart; but the evidence is indubitable that stimulants of various kinds applied directly to the capillary arteries, without in the least

the heart's action, are capable of modifying to a great extent the action of the capillaries; sometimes, for example, causing them to contract and at other times to dilate; sometimes quickening the flow of the blood through them; at other times retarding it, and frequently altogether arresting its progress. It is manifest that this contractile power of the capillaries must be a vital endowment, for no such property is possessed by any substance destitute of life; and there is satisfactory evidence that it is communicated, regulated, and controlled by the organic nerves, which it has been stated increase as the size of the vessels and the thickness of their membranous coats diminish. 'The powerful influence of these nerves upon the capillary vessels is placed beyond doubt or controversy by the obvious local changes produced in the capillary circulation by sudden and even by mental impressions; by the flush of the cheek and the sparkle of the eye at a thought conceived or a sound heard; changes which can be effected, as far as we have any knowledge, by no medium excepting that of the nerves.'

Of the real nature of the phenomena which take place in the capillary vessels we are wholly ignorant; but it is probable that they consist of the conjoint operation of mechanical, chemical, and vital actions, the combined influence of which on the constitution of the blood, the pabulum of life, in the primary and essential functions of life, is thus stated by the author of the 'Philosophy of Health':—

'Exerting upon each other a vital force of repulsion, under a vital influence derived from the organic nerves, urged by the vital contraction of the heart, the particles of the blood reach the extreme capillaries. Most of these capillaries terminate in canals, which they work out for themselves in the substance of the tissues. The tissues are endowed with a vital attractive force, which they exert upon the blood—an elective as well as an attractive force; for in every part of the body, in the brain, the heart, the lung, the muscle, the membrane, the bone, each tissue attracts only those constituents of which it is itself composed. Thus the common current, rich in all the proximate constituents of the tissues, flows out to each. As the current approaches the tissue the particles appropriate to the tissue feel its attractive force, obey it, quit the stream, mingle with the substance of the tissue, become identified with it, and are changed into its own true and proper nature. Meantime the particles which are not appropriate to that particular tissue, not being attracted by it, do not quit the current, but, passing on, are borne by other capillaries to other tissues to which they are appropriate, and by which they are apprehended and assimilated. When it has given to the tissues the constituents with which it abounded, and received from them particles no longer useful, and which would become noxious, the blood flows into the veins to be returned by the pulmonary heart to the lung, where, parting with the useless and noxious matter it has accumulated, and replenished with new proximate principles, it returns to the systemic heart, by which it is again sent back to the tissues.'

'Particles of blood are seen to quit the current and mingle with the tissues: particles are seen to quit the tissues, and mingle with the current. But all that we can see with the best aid we can get does but bring us to the confines of the grand operations that go on, of which we are altogether ignorant. Arterial blood is conveyed by the arteries to the capillaries; but before it has passed from under the influence of the capillaries, it has ceased to be arterial blood. Arterial blood is conveyed by the carotid artery to the brain, but the cerebral capillaries do not deposit blood, but brain. Arterial blood is conveyed by its nutrient arteries to the bone; but the osseous capillaries do not deposit blood, but bone. Arterial blood is conveyed by the muscular arteries to muscle; but the muscular capillaries do not deposit blood, but muscle. The blood conveyed by the capillaries of brain, bone, muscle, is the same; all comes alike from the systemic heart, and is alike conveyed to all tissues; yet in the one it becomes brain, in the other bone, and in the third muscle. Out of one and the same fluid these living chemists manufacture cuticle, and membrane, and muscle, and brain, and bone; the tears, the wax, the fat, the saliva, the gastric juice, the milk, the bile, all the fluids and all the solids of the body.'

'And they do still more, for they are architects as well as chemists; after they have manufactured the tissue they construct the organ. The capillaries of the eye not only form its different membranes and humours, but arrange

them in such a manner as to constitute the optical instrument; and the capillaries of the brain not only form cerebral matter, but build it up into the instrument of sensation, thought, and motion.' (See Dr. Craigie's *General Anatomy*; Grainger's *Elements of General Anatomy*; Dr. Southwood Smith's *Philosophy of Health*.)

CAPITAL. In the article ACCUMULATION we have shown the manner in which savings become capital, or accumulations capable of producing profit. The surplus of production which remains, either in the shape of national or individual wealth, after a portion of what is produced has been consumed, is capital; and this capital, conjoined with new labour, produces a further surplus or profit. The capital of an industrious nation, having its industry developed under wise institutions, is thus constantly increasing. It will not be convenient, in this place, to enter into any minute details having reference to the various forms in which capital is accumulated, or to show its operations in the creation of profit in conjunction with labour. As far as such large subjects, which involve minute illustrations, can be properly treated in a Cyclopædia, they are noticed under the heads of INTEREST, PROFIT, RENT.

CAPITAL. [COLUMN.]

CAPITANATA, a province of the kingdom of Naples corresponding to the ancient Daunia or original Apulia, for the Apulia of the Romans was more extended, and included also Peuceia the present Terra di Bari. [APULIA.] The word Capitanata is a corruption of Catapanata, a word derived from catapan, the name given to the Greek or Byzantine governor of this province under the eastern emperors. The province is also vulgarly called Puglia Piana, to distinguish it from Puglia Pietrosa or Terra di Bari and Otranto. Capitanata is bounded N.E. by the Adriatic, N.W. by the Sannio (formerly Contado di Molise), from which it is divided first by the upper course of the Fortore, and lower down by the small river Saccione, half way between the Fortore and the Biferno. Until of late years the limits of Capitanata extended beyond the Biferno to the boundaries of Abruzzo Citra near the mouth of the Trigno; but, by the new limitation of the provinces, the maritime district of Termoli, on the left bank of the Biferno, and that of Ururi on the right bank of it, have been added to the Sannio. To the S.W. Capitanata is bounded by Principato Ultra, from which it is divided by the central Apennine ridge, and to the S.E. by Basilicata and Terra di Bari, being divided from both by the course of the Ofanto. The length of the province from the mouth of the Saccione to that of the Ofanto is 80 miles, and its breadth from the pass of Bovino to Manfredonia is about 50 miles. The greater part of Capitanata consists of a wide plain sloping gently from the foot of the Apennines to the Adriatic. In the N. part of the province the insulated group of Mount Gargano projects eastwards into the sea, forming a peninsula, which from its shape and position has been called the Spur of Italy. To the N.W. the districts of Torre Maggiore, Lucera, and Vulturara, lie among offsets of the Apennine ridge. To the W. the towns of Troja and Bovino, and to the S. that of Ascoli rise at the foot of the ridge itself. [ASCOLI DI S. TRIANO.] All the rest is a vast monotonous plain, without trees, with hardly any villages or houses, and with only the town of Foggia in the middle of it, and the small town of Corignola, 25 miles S.E. of Foggia, near the Ofanto. This plain is known by the name of Tavoliere di Puglia. The chief rivers are, the Fortore, which enters the sea near Lake Lesina; the Celone and Candelaro, which are formed of several branches rising in the Apennines and in the offset which fills up the peninsula of Gargano, these two rivers afterwards uniting in one stream under the name of Candelaro, which enters the Lago Salso a little S. of the town of Manfredonia; and the Cervaro and Carapella which unite near the sea a few miles N. of Lake Salpi. The Ofanto (the Roman Ausidus) is the largest river of the province. It rises in the central Apennines about twenty-five miles N.E. of Salerno, on the opposite coast, and enters the sea after a rapid course of about sixty miles.

The surface of Capitanata is 2350 square miles, forming 2,387,780 moggia (the moggia is somewhat less than the English acre), divided among 42,000 proprietors (many of them only house proprietors), out of 273,000 inhabitants. The number of proprietors has been decreasing during the last ten years; in 1824 they were 57,500. About one-sixth of the surface, among the hilly regions of Gargano and the

Apennines, is covered with forests and plantations of trees. The great plain of the Tavoliere occupies 1,120,000 moggia, or nearly one-half of the surface of the province. Two-thirds of this plain are left for pasture and have no resident population, and the other third is cultivated, excepting 50,000 moggia of it, which are covered with marshes. The history of the Tavoliere is interesting. Daunus, by the Roman invasion, was well inhabited; and had many towns. In the second Punic war the devastation of the country was commenced. The wars of Sulla and the servile war of Spartacus completed the desolation. The towns and villages of the plain being destroyed, the inhabitants became wanderers and shepherds. The course of the rivers and the drains being neglected, pestilential marshes were formed near the sea coast, while the inland plain, deprived of irrigation, was burnt up by the summer heats. In winter, however, it afforded a natural and abundant pasture. The mountaineers of Samnium and Abruzzo, whose countries had also suffered their share of Roman devastation, being mostly reduced to the condition of shepherds, began to lead their flocks in winter into the plains of Apulia, which were abandoned, and returned to the mountains for the summer. This was the origin of the 'pastorizia errante,' or the system of migratory pasturing, which has continued ever since. The Romans established a *vectigal* or gabella upon the flocks and cattle which were led to pasture in the plain, and intrusted its management to Publicani called 'Alabar-chi,' who numbered the heads of cattle or sheep, and collected the tax. (See Ducange's *Glossarium*, art. 'Alabar-chi.') Under the emperors the complaints of the extortions of the Publicani became so loud that Nero proposed to the senate the abolition of the vectigal, which however was not effected. Things continued in the same state for centuries after the fall of the empire. The towns of Salapia, Argyrippa, Anxanum, Herdonia, &c., had disappeared. Sipontum still survived in a state of decay until the Norman Manfred removed its inhabitants to the new town of Manfredonia. Under the Normans the Tavoliere was made a fiscal or royal property, and parts of it were let to 'locati' or tenants. Charles of Durazzo drove away the tenants. Alfonso of Aragon, by letters-patent, dated from Tibur 1st of August, 1447, organized anew the gabella on the sheep and cattle, by which the proprietors of flocks in the mountains of Samnium and Abruzzo were obliged to take them into the plain of Puglia for the winter, and to pay a tax at so much per head.

In 1661 this obligatory migration was commuted into a voluntary one, by which every proprietor of flocks obtained the quantity of ground that he wanted for pasture, by paying to the treasury 132 ducats a year for every 1000 sheep. Other parts of the plain were let for cultivation. Under King Joseph Bonaparte, in 1806, all the temporary tenants of the Tavoliere were obliged to become *enfiteuti*, or perpetual tenants, and to purchase their lands, under which regulation 1,800,000 ducats were paid at once into the treasury. In 1817, after the restoration, a second *fisc* to the same amount was exacted, and the annual charge was also raised; at the same time the peace lowered the price of agricultural produce. A hail-storm in 1822 and cold winters completed the distress of the tenants. Some relief has been afforded to them since by the government remitting part of the arrears, and granting delay for the rest. There are 2300 *enfiteuti* or perpetual tenants in the Tavoliere; the annual charge on the pasture-land is 346,000 ducats; that on land in cultivation is about 600,000. The monti frumentarii, which exist here as in other parts of Italy [BRESCIA], and which lend corn for seed or consumption to poor cultivators at a small interest, have increased. The breed of sheep has been improved by the cross of merinos, and the wool, which was once very coarse, is now doubled in value, being 80 ducats the cantaro (about 200 lbs. English). In 1834 the quantity of wool produced was about 80,000 rubbi. The breed of horses has also been improved; and winnowing and threshing machines have been introduced. Notwithstanding the dryness of the soil and the little manure used by the cultivators, wheat thrives very well on it. Capitanata exported, in 1833, through the ports of Manfredonia and Barletta, 269,907 cantari of wheat, 5094 of barley, 6139 oats, 1568 Indian corn, 6281 beans, and about 200 of peas. From the Gargano, which is the best cultivated district in the province, oil, lemons, oranges, carobs, capers, and tobacco are exported to the annual

value of 75,000 ducats a year. Large sails from the lakes of Varese and Losino, in the same district, are exported chiefly to Naples, to the amount of 16,000 ducats. Cheese, cattle, and ponies form the other articles of exportation. The manufactures are very few, consisting of some linens made at Cerignola; coarse hats, leather, common soap, &c. Capitanata owns only 24 vessels, 12 of which are merely coasting boats. Manfredonia is the only harbour in the province, but there is not depth of water for large vessels. The town is well built, has a castle, several churches, an archbishop's see, and 8000 inhabitants. Near Manfredonia are salt-works of marine salt. The Sipontine marshes in the neighbourhood, which affected the health of the town, have been lately drained. The Candelaro, Celone, and other rivers, have been embanked to prevent fresh inundations. A canal was cut in 1830 for the waters of the Candelaro to the sea. By these means several thousand moggia of ground have been recovered. The marsh called Lago Salsi, between the Candelaro and the Cervaro, is about four miles in length and two in breadth. Further E. along the coast, and between the mouth of the Carapelle and that of the Ofanto, is the great marsh called Lago Salpi, 20 square miles in extent and only 2 feet in its greatest depth; it is nearly dry in summer, and poisons the air all around. Several projects have been formed for drying it up, but none have yet been carried into execution. Two miserable villages, Salpi and Casal Trinità, are near its borders.

Foggia, the capital of Capitanata, is a well built modern town of 21,000 inhabitants, the seat of the provincial courts of justice, of a commercial court, and the centre of all the trade of the province. Around Foggia are plantations of olives, vines, and other fruit trees, which form an oasis in the midst of a desert. Many of the provincial nobility and gentry reside at Foggia. The great road from Naples to Barletta, Bari, &c., passes through Foggia, whence other roads branch off to Manfredonia and Mount Gargano, to San Severo, and to Lucera. Foggia is 78 miles E.N.E. of Naples, and 20 S.W. of Manfredonia. Lucera, 10 miles W. of Foggia, is built on a hill, with an old castle of the time of Frederick of Suabia, a fine old cathedral, a royal college or gymnasium, a bishop's see, and a population of 8000. San Severo, at the foot of Mount Gargano, 18 miles N.W. of Foggia, is a bishop's see, and has 10,000 inhabitants. Monte Sant' Angelo, built on Mount Gargano, 9 miles N.E. of Manfredonia, is in a romantic situation, and contains the cave and sanctuary of St. Michael. At the back of Mount Gargano is the small town of Viesti, on the Adriatic coast. In the south part of the province are Bovino with 3000 inhabitants, Troja, and Ascoli already mentioned; (Asan di Rivera, *Considerazioni sulle due Sicilie; Lettere da San Severo*, in No. 18 of the *Progresso*, a Neapolitan journal, which gives a good statistical sketch of the province.)

CAPITOL, CAPITOLIUM, MONS CAPITOLINUS, a hill, a fortress, and a temple, celebrated in the history of ancient Rome. The temple and the fortress no longer exist; and the hill is called by corruption Campidoglio. It rises on the eastern skirts of the inhabited part of modern Rome, which it divides from the Forum and the other forsaken districts of the ancient city. The Capitoline Mount is of an oval shape, and about one mile in circumference at its base; it is divided from the Quirinal to the N.E. by a narrow valley, in which the Forum of Trajan once was, and the pillar still is; it has to the E. the Forum of Augustus and the Via Sacra, which divides it from the Esquiline hill; to the S.E. the valley of the Forum Romanum, which divides it from the Palatine hill; to the S. the Forum Boarium, which divides it from the Aventine hill; and the Tiber to the S.W. It has two summits, one to the N. towards the Quirinal, on which the church and Franciscan convent of Ara Coeli now stand; and another to the S. towards the Tiber, on which are the palace and garden of Caffarelli. At the S. end was the Tarpeian rock, down which state criminals were hurled. The height of this side of the hill is very much reduced, the ground at the foot of it having been considerably raised by ruins and rubbish, and the rock itself having been sloped down, and houses built against it. Still it rises abruptly in one place, to the elevation of 20 palms (65 feet), at the back of the Caffarelli garden, where Piazza Montemara. The height of the Capitol, taken at the summits of the church of Ara Coeli, which is the highest summit, is 155 feet above the sea, 135

above the Tiber taken at its medium height, and about 90 feet above the present surface of the Forum, which however is in several places 20 feet higher than its ancient level.

This hill is said to have been called Saturnus in the ante-Roman times. When the first Romans built their town on the Palatine, they chose the opposite hill, which was then more abrupt, to build their ark or citadel upon. In their first war with the Sabines, according to the old story, the latter took possession of this strong hold by the treachery of a woman called Tarpeia, the daughter of the Roman commander. Hence the hill took the name of Tarpeius. After the peace Tatius and his Sabines settled on the Tarpeian Mount, and Romulus remained on the Palatine. Tarquinius the Elder began to build a temple to Jupiter on the Tarpeian Mount, the summit of which he levelled for the purpose. The building was afterwards continued by Tarquinius Superbus, who engaged workmen from Etruria for the purpose, and employed in it the money resulting from the plunder of Suessa Pometia, a city of the Volsci, which he had taken and destroyed. Wishing the place to be wholly consecrated to Jupiter, he ordered the chapels and votive altars erected by Tatius and others to be removed. The augurs consulted the flight of birds to ascertain the will of the gods, and all were declared to have assented except the god Terminus, who would not stir from his place. This was considered as an omen of the perpetuity of the new edifice and of the city. In digging some part of the foundations, the workmen were said to have found a human head quite fresh, which was interpreted to signify that the spot would be the head and centre of the Roman power. (Livy, i. 55.) The temple was accordingly dedicated to Jupiter Capitolinus, from caput, 'a head.' It has been a subject of dispute whether this temple stood on the N. or S. summit of the hill; it seems probable, however, that it stood on the N. side, where the church of Ara Coeli now stands. (Nardini, Ficoroni, &c.) It is said to have stood *in arce*, 'in the citadel,' which was originally on the S. summit; but as the entire mount was afterwards inclosed by walls and fortified, the word *arx* was used indiscriminately for the whole. The temple is said to have had its front to the S. towards the Aventine; had it been at the S. extremity, there would have been no access to it, except at the back, by the Clivus Capitolinus. This is one of the arguments used by Nardini and others. The temple of Jupiter Capitolinus was burnt in the civil war of Marius, but Sulla rebuilt it with much greater splendour and of the most costly materials. It is said to have been 200 feet long and 155 wide; it had a peristyle with three rows of marble columns in front, and two rows of pillars divided the interior into three aisles, at the furthest end of which were three cellas dedicated to Jupiter, Juno, and Minerva. The vault of the temple and the external roof were covered with plates of gold. This temple was the principal sanctuary of Rome, to which the victorious generals and emperors went in triumphal procession to sacrifice to the gods. Other temples were raised successively on the Capitoline hill, such as that of Juno Moneta, with the mint annexed to it; of Jupiter Feretrius, said to have been built by Romulus; of Mars, of Venus, of Fortune, and of Isis and Serapis. The temple of Concord stood on the slope towards the Forum. A Bibliotheca or Library, the Tabularium, Athenæum, Curia Kalabra, the Atrium publicum, and other public buildings, were also on the Capitol. In the intermontium or little valley between the two summits, stood the Asylum or place of refuge, between two plantations of oak trees. It is difficult now to form an idea of the appearance of the place and the effect it must have produced. It is evident that the sides of the hill were much more abrupt and stood higher above the plain below than at present. The only access was from the Forum on the S. side by the Clivus Capitolinus and the Clivus juxta Asylum. There were also 100 steps to ascend to the Tarpeian rock, being probably an opening on that side branching out of one of the two Clivi.

The principal buildings of the modern Capitol consist of three palaces, the work of Michel Angelo, forming three sides of a square, in the middle of which stands the equestrian statue of Marcus Aurelius. The open side is to the N.W. towards the modern city. The palace facing it is that of the senator of Rome; to the left of it is the palace of Conservatori; and to the right that of the Capitoline

Museum, one of the finest collection of statues and sculptures in Italy. The three palaces and the square between occupy the intermontium, the two summits being occupied by the church of Ara Cœli and the palace and gardens of Caffarelli. Two ways lead down by the senatorial palace into the Campo Vaccino, or ancient Forum.

CAPITULARIUM, literally 'a book divided into chapters,' was the name given to the laws issued by the French kings of the first and second races, in the great assemblies of the nobles and bishops which formed the states of the kingdom, for the administration of civil and ecclesiastical affairs. These laws, being classed under heads or chapters, were called capitularies. Childbert, Clotaire, and Dagobert, and afterwards Charlemagne, Louis le Débonnaire, Charles the Bald, &c. issued capitularies. Those of Charlemagne are the most celebrated, being more extensive, more enlightened considering the age he lived in, and forming a real code of legislation which remained in force long after. Ansgarius, abbot of Fontenelles, made a collection in books of the capitularies of Charlemagne and his son Louis le Débonnaire in the year 827. Other collections were published subsequently. After Charles the Simple, A.D. 927, no more capitularies were issued, and no laws or statutes are known to exist of the subsequent period till the time of Louis le Gros A.D. 1100. Louis le Gros began to issue charters to the community of churches, but no general laws or ordinances appear to have been enacted except one by Philippe Auguste in 1190 till the time of St Louis, A.D. 1200 who began to issue regular ordinances. Baluze published a complete collection of all the capitularies issued by the kings of the first and second race, with notes—*Capitularia Regum Francorum*, 2 vols. folio, Paris, 1677.

CAPITULATION—series of articles expressing the conditions under which a fortress is surrendered to an enemy.

The agreement by which an army or a large division of troops surrender to a superior force or engages to evacuate the territory which it occupies, when its strength and condition is such as to make itself respected by the enemy is called a Convention. Such was that made at Cuthbert or rather at Lisbon, between the general of the French and English armies on the departure of the fortress from Portugal in 1808.

When the provisions and ammunition of a garrison are nearly expended when injuries have been met in the ramparts of the fortress, and no chance remains of being succoured, the governor of the place is put under the necessity of entering into an agreement with the besiegers respecting the terms by which he consents to deliver his charge into their hands, and by the rule of war as well as from the regard due to a gallant adversary, he is entitled to obtain in honourable capitulation. It may be observed that if the governor should postpone the proposals to surrender till his provisions are entirely exhausted, the besiegers may refuse to grant terms to the garrison, which must then surrender at discretion.

When the reign of Napoleon was drawing to an end, and he found himself reduced to the necessity of acting on the defensive, the duty of defending the fortresses of France impressed on the commanders by every motive which the love of glory and the fear of disgrace can inspire. In this important decision concerning them it is stated that every commander who shall appear to have defended his fortress like a man of honour and a faithful subject, shall done with the officer and soldiers who may have distinguished themselves in the defence, be presented on a day of general parade, and receive, in presence of the troops, public testimonials of the emperor's satisfaction that no time shall be lost in exchanging those who may be made prisoners of war, and that every commander who shall be killed on the breach or die of his wounds, shall be buried with the same honours as a Grand Cross of the Legion of Honour. On the other hand it is stated, that every capitulation made without a vigorous resistance continued to the last moment and without having sustained at least one assault on the rampart of the place, is criminal and dishonourable. The commander who so surrenders is made responsible for all the consequences of his cowardice or treachery, he is threatened with all the severity of the law and the decree consigns to infamy, and punishes with death, him who yields to the menaces or proposals of the enemy.

If the resolution to surrender should be at length taken,

the conditions proposed by the besiegers should be such only as are consistent with the circumstances of the case. The governor should however firmly insist upon their execution when granted. He is not to separate himself from his garrison, but he must share its fate as well after as during the siege, and he is to stipulate in favour of the sick and wounded for as many advantages as he can possibly gain.

It has happened that the governor of a fortress has been induced to leave his post by an invitation to a personal conference with the general of the besieging army, and that advantage has been taken of his absence to assault the place in the hope of gaining it during the confusion then expected to prevail there. History moreover records instances in which the besieging troops have entered the place and committed disorders even while the commanders have been occupied on the breach in drawing up the articles of the capitulation. To avoid such misfortunes the governor of a fortress should on no account go out for the purpose of the thing with the enemy, but he must employ in that duty officers on whose zeal and firmness he can rely.

By the terms of a capitulation the arms and military stores in the place are generally given up to the besiegers, the officers and troops of the garrison retaining only their private property, and being allowed to march out with the honours of war, that is, with drum beating, colours flying, &c. When necessary a convoy is allowed them for protection till they arrive at the place of their destination.

CAPITULUM, a head of flowers, a particular form of inflorescence. Theoretically botanists consider it an undelimited spike, the axis of which becomes a receptacle, and the external empty bracts an involucre. The dandelion, and all Compositæ, have an inflorescence of this nature. It is vulgarly looked upon as a flower.

CAPO DISTRIA a seaport town of Istria, on the Adriatic Sea. It stands on an egg-shaped island, which is connected with the main land by a long causeway. The town is about two miles in circumference, it has some trade, and is considered much healthier than most of the places on that coast. The port trade is chiefly supplied by the salt pans in the neighbourhood, and by the vineyards, which afford a quantity of good wine.

CAPO DISTRIA, the Count of, born at Corfu in 1770 was the son of a physician, and he himself began to study medicine at Venice, to which a public Corfu and the other Ionian islands then belonged. His father was chief of the provisional government of the Ionian islands in 1799, when the Russians took possession of them. In 1806, when the Seven Islands, by the treaty of Tilsit, were placed under the protection of Bonaparte, both Capo d'Istria and his father left Corfu and entered the service of Russia. The count's first post was an humble one, but as he showed a talent for diplomacy, he was speedily advanced and attached to the Russian embassy at Vienna. In 1812, during Bonaparte's expedition to Moscow, Capo d'Istria was charged with certain diplomatic operations connected with the army of the Danube, or, as it is more commonly called, the army of Moldavia, under the command of Admiral Tchitchagof, which had been engaged against the Turks and then occupied the two principalities of Wallachia and Moldavia. When (in the summer of 1812) peace was concluded between Turkey and Russia, and the latter power was enabled to recall the army of Tchitchagof from the Danube to the Berezina, Capo d'Istria went with it, and after the finishing blow given to the French at the passage of the Berezina, he remained at the head quarters of the Emperor Alexander of Russia, who formed a high opinion of his abilities and address. In 1813 he was sent by Alexander as his minister plenipotentiary to Switzerland, and, before the allied armies crossed the Rhine into that country, he drew up a declaration promising the re-establishment of Helvetican independence and the restitution of all the territory that the French had taken from the Swiss. These promises were well kept, and the Count so conducted himself as to merit the esteem of the Swiss. The Constitutional Act, which he sanctioned and forwarded, removed many old abuses and invidious distinctions. In September, 1814, Capo d'Istria left Switzerland for the Congress of Vienna, where, mainly through him, the affairs of the Swiss were happily terminated. In 1815 he was with the Emperor Alexander at Paris, and was his plenipotentiary in the definitive treaty of

with France. In the course of his last he advanced the cause of education, and wrote the emperor an account of the establishment of M. Fellenberg at Hofwyl. This letter, in the form of a pamphlet, was published at Paris in 1816, in the course of which year the Grand Council of Lausanne gave the count the citizenship of the Canton of Vaud. A short time afterwards he was recalled to St. Petersburg by the Emperor Alexander, who appointed him one of his secretaries of state for foreign affairs, the duties of which office he divided for some time with Count Nesselrode. Capo d'Istria had a principal share in the diplomatic underminings of the Turkish empire which took place from 1815 to 1827, when Russia entered into Mr. Canning's treaty of alliance, (in which, with England and France, she was to preserve Greece from destruction,) rather with the view of injuring and weakening Turkey than from any affection for the Greeks. Notwithstanding these circumstances, however, Capo d'Istria was allowed to take upon himself the office of president of the Greek government, in which he was regularly installed early in the year 1828, or a few months after the battle of Navarino.

We cannot go into the long question of his almost constant dissensions with the people whom he was sent to govern. There were evidently faults on both sides—on both sides violence, obstinacy, duplicity, and intrigue; but making many allowances for the Greeks, the opinion of most of those who watched his administration in the country was very unfavourable to the Count, who was not merely suspected of a desire to make himself king or perpetual and despotic president of the Greeks, but also to render Greece wholly subservient to Russia. Some memorable letters which he wrote to Prince Leopold of Saxe-Cobourg (now king of the Belgians), to whom the Greek crown had been offered in 1829, mainly induced that prince to decline accepting it, which he did definitively on the 21st of May, 1830. On the 9th of October of the following year, Capo d'Istria was assassinated at Napoli di Romania, on the threshold of a church, by George, the son, and Constantine, the brother, of Pietro Mauromichali, the old bey of Mania, whom he had detained for many months in prison without trial or even a specific accusation. Some circumstances connected with this event, and with the general conduct of Capo d'Istria, are given by Thiersch in his *Etat Actuel de la Grèce*, Leipzig, 1833.

CAPONNIERE, in fortification, is a passage protected on the right and left by a wall or parapet. The term is generally applied to that by which the communications are made across the main ditch of a fortress to the outworks [BASTION, G. fig. 1], or from the covered-way to the gorge of an advanced work. When a passage exposed on one side only is thus protected it has the name of a demi-caponniere.

The protecting parapet is generally of earth, with its upper surface descending gradually to the bottom of the ditch, in order that the enemy may be completely exposed in advancing up to it, and also that the ditch may be defended by a grazing fire from thence. A passage of this kind is however exposed to the plunging fire of the enemy from the crowning battery H, and from that which should correspond to it on the left hand of the front of fortification; it may therefore be further protected by a *parados* or elevation of earth extending along its centre; for by this the defenders behind both parapets would be effectually concealed.

Sometimes the caponniere is a vaulted gallery of brick-work, the sides of which are pierced with loop-holes or narrow openings, for the defence of the ditch by a fire of musketry. In this case a trench is cut on the exterior, and parallel to each side of the work, in order to prevent the enemy from approaching near enough to annoy the defenders within.

Palisade caponnières are formed across the ditches of field-redoubts when those ditches are incapable of being defended from the parapets. If covered with a roof for protection against shells or grenades; that roof should be kept below the natural ground, in order that it may be concealed from the view of the enemy at a distance.

CAPPADOCIA, a country of Asia Minor, usually spoken of in two divisions—1. Cappadocia the Great, or Cappadocia bordering on the Taurus (Strabo), also called Cappadocia simply; and 2. Cappadocia bordering on the Pontus, and called Pontic Cappadocia. Cappadocia on the Pontus includes the country N. of the range of mountains anciently

called the *Taurus*. Taken in its largest extent, Cappadocia included nearly the whole of the Turkish provinces of Roum, and a great part of Karamania. It was bounded on the N. by the Pontus Euxinus (Black Sea), on the S. by Taurus, which divided it from Cilicia, on the W. by Paphlagonia, Phrygia, and Galatia, and on the E. by the Euphrates. Both the Cappadocians (*Kappadokiai*) on the Pontus and those bordering on the Taurus were called Syrians (*Σύριοι*) by the Greeks, and White Syrians (*Λευκοὶ Σύριοι*), to distinguish them from the Black Syrians beyond the Taurus. (Herod. i. 72, v. 49; Strabo, xvi. p. 737, α, Casaub.) Cappadocians was the name given them by the Persians. (Herod. vii. 72.) There is a river Cappadox, mentioned by Pliny, rising in some of the mountain-ranges, and flowing along the boundary of Galatia and Cappadocia into the Halys: the name is not mentioned by Strabo; and it is probably of comparatively late origin. Some writers however have derived the name of the country from the river.

Our information on this important country has not been much increased by modern travellers: we are still indebted chiefly to Strabo, who however, considering that Amasia on the Iris (Yeshil-Ermak) was his birth-place (Strab. xii. p. 561, δ.) has not told us more than we might have expected. Cappadocia is one of the richest parts of Asia Minor; it is characterised by extensive plains of great fertility. Of the mountains the principal is the Taurus, which forms in fact the southern boundary. Two other important chains, the Anti-Taurus and the Paryadres (Keldir), run nearly parallel from Armenia into the centre of Cappadocia, where they form the high ridges of Mount Argæus (Argis-Dagli). From the summit of Mount Argæus Strabo says (xii. p. 538), that the few who had ever gone so high had been able to see the Black Sea and the Gulf of Scanderoon, an assertion which is confuted by the bare inspection of a map. Argæus is said to be covered with perpetual snow. Cappadocia the Great generally has little wood; almost the only timber district is in the neighbourhood of Mount Argæus which supplies the rest of the country with fuel. Beyond this woody region which surrounds the mountain is a sandy plain with a substratum of rock, quite barren and uncultivated. The part between Mount Argæus and Mazaca (Kesarieh), and indeed most of this district, appears to have been the seat of volcanic action (Strab. xii. p. 538): it abounds in water, chiefly marshes caused by the overflow of the river Melas. On the banks of the Melas were some large stone quarries, which supplied the people of Mazaca with building materials, but which appear to have been sometimes rendered nearly useless by the badness of the air, owing to the exhalations from the river. Mazaca was the favourite abode of the kings of Cappadocia, who appear to have selected it for its central position, and because it abounded in timber and in stone as well as in fodder, which was a great object where so much attention was paid to cattle. (Comp. Xen. *Cyrop.* ii. 1. 5.) The tribute which they paid to the Persian monarch consisted chiefly in horses, mules, and sheep. The high table-lands of this country are admirable pasture land; and it is probable that in very early, as well as in later times, the Cappadocians carried on an extensive trade in supplying the neighbouring nations with horses and mules. (Ezekiel xxvii. 4.)

The principal towns of Pontic Cappadocia were on the coast. A little E. of the mouth of the Halys was Amisus (Samsun); farther E. on the river Thermodon stood Themisycra, whose plains were the fabled abode of the Amazons: proceeding along the coast we come to Cerasus (*Κερασινούρις*), the modern Kharesoun, where cherry-trees grow wild in great abundance on the hills (Tournefort, *Relat. d'un Voyage au Levant*, ii. p. 221); it was from this place that Lucullus first brought cherries into Italy on his return from the Mithridatic war. The word 'cherry' (*cerasus*) is said to be derived from the name of the place. Just upon the eastern boundary of Cappadocia on the Pontus stands Trapezus (*Τραπεζοῦς*), the modern Trebizond, originally a Greek city, a colony from Sinope (Xen. *Anab.* iv. 8. 22), where the Greeks met with an hospitable reception on their retreat after the battle of Cunaxa. Trapezus and Cerasus paid tribute to Sinop. (Xen. *Anab.* v. 5. 10.)

The chief towns inland were Amasia, Mazaca, Comana (in Pontus), the great emporium for the Armenian merchants (Strab. xii. p. 559), and Comana in Cappadocia the Great, the modern Bostan, which contained a great temple of Bellona. To the W. of Comana, near the bound-

dary of Lycaonia, was Tyana, or as Xenophon (*Anab.* i. 3, 20.) calls it, *Dap*, the limit of Cyrus's march in Cappadocia. The principal rivers of Cappadocia are the Halys (Kizil-Ermak) and the Iris (Yeshil-Ermak), both of which flow into the Euxine; and the Melas, which flows into the Euphrates. The Kizil-Ermak flows through a country abounding in salt-hills, and hence Strabo supposes the ancient name to have been derived (xii. p. 546, d.). Indeed in many parts of Cappadocia salt tracts are found of great extent. The Halys rises further to the E. than is represented in the ordinary maps, and runs for about half its course from W. to E. in a longitudinal valley. It then turns to the N. and cuts through the mountain-ranges, all of which have a general direction parallel to that of the Euxine coast. [ANATOLIA.] The Iris flows through Amasia.

Cappadocia abounded also in mines of iron and silver: Horace alludes to this fact. (*Epist.* i. 6. 33.) The iron mines in the N.E. of Pontus were worked by the Chalybes (*Chalybes*, Strab. xii. 549, d.; see Xen. *Anab.* v. 5. 1), the greater part of whom appear to have gained a livelihood by working in iron. On the same coast E. of Samsun (Amisus) at a place called Unich, rock alum still forms a considerable article of trade. There is said to be a silver mine at a place near Amasia, called now Hadji Kioi. Crystal, jasper, and onyx are said also to enrich this country. (Strab. p. 540, a.) Strabo speaks of a beautiful stone which was produced in Cappadocia, white like ivory; the handles of swords were made of it.

The Cappadocians were very generally known during the Roman occupation of their country for their unprincipled and vicious character; so much so that the word 'Cappadocian' was only another name for a villain.

The condition of Cappadocia before the period of the Persian rule is uncertain; possibly it belonged to the extensive kingdom of Lydia. At any rate both Cappadocia on the Pontus and Cappadocia on the Taurus appear to have formed one state. Darius Hystaspis is said to have first divided it into two satrapies. (Strab. xii. 534, c.) The satraps appear to have been kings of the countries tributary to the Persian monarch, and hence an hereditary succession is observed. The circumstance that Darius and his successors, in this, as in most other cases, left the government of the district with the native princes, is probably to be attributed more to their inability to prevent it than to any other reason.

The first king of Cappadocia, according to Strabo (xii. p. 534, a), was Ariarathes. But Aribæus, mentioned by Xenophon (*Cyrop.* ii. 1, 5), would appear to have preceded him. The following list has been drawn up in the *Universal History* (vol. x. p. 8)—Pharnaces, Smerdis, Atamnas, Anaphas, Anaphas II., Datames, Ariaramnes, Ariarathes I., Olophernes, Ariarathes II., Ariarathes III., Ariaramnes II., Ariarathes IV., Ariarathes V., Ariarathes VI., Ariarathes VII., Ariarathes VIII., Ariarathes IX. (the family of Pharnaces now extinct), Ariobarzanes I., Ariobarzanes II., Ariobarzanes III., Archelaus. On the death of Archelaus Cappadocia was reduced to a Roman province (Strabo, xii. p. 534), which it continued till it was invaded by the Turks.

On the division of Cappadocia by the Persians Pontus was given over to one of the ancestors of Mithridates, according to Justin and other writers. The following is a list of the kings as they have been mentioned in history:—Artabazus (an interval of perhaps 80 years then occurs), Rhodabates, Mithridates I., Ariobarzanes, Mithridates II., Mithridates III., Ariobarzanes II., Mithridates IV., Mithridates V., Pharnaces I., Mithridates VI., Mithridates VII., surnamed the Great, with whom the Romans waged the celebrated Mithridaticum Bellum (he died B. C. 64); Pharnaces II., Darius, Polemon I., Polemon II. Pontus was then reduced entirely to a Roman province (Tacit. *Hist.*, iii. 47), which it continued till the time of Alexius Comnenus, in whose family the empire remained till Mohammed II. reduced it to slavery.

(British Museum. Actual size. Silver. 61 grains.)

CAPPARIDACEÆ, a natural order of dicotyledonous polypetalous plants, having a superior fruit, parietal placentæ, an embryo curved upon itself without albumen, four petals and sepals, a great number of stamens, and an ovary elevated upon a long stalk. They are known from Cruciferae by their indefinite stamens and reniform seeds. All of them appear to be more or less acrid. They are bushes or herbs found all over the tropics, and not extending in many places beyond them. Egypt and the south of Europe, which are inhabited by *Capparis spinosa* and similar species, offer the greatest exceptions to the rule.

Some of the American species of *Capparidaceæ* are very poisonous; others act as vesicatories; and a few are merely stimulant. To the latter class belongs the *Capparis spinosa* of the south of Europe. This plant grows naturally upon rocks and ruins all over the south of France and Italy, rendering them inconceivably gay with its large white blossoms, from the centre of each of which there springs a long tassel of deep lilac stamens. The flower-buds constitute the capers of the shops, the quality of which depends exclusively upon the age at which they are gathered, the smallest and youngest being the dearest and most delicate, and the largest and oldest the coarsest and cheapest. On an average each plant of the Caper bush gives a pound of buds. The consumption of capers in this country is inconsiderable, not amounting to more than about 60,000 lbs. a-year.

[*Capparis spinosa*.]

1, an expanded flower; 2, a petal; 3, a calyx with the stalked ovary; 4, a horizontal section of the fruit; 5, a longitudinal section of the seed; 6, an embryo extracted from the seed-coat.

CAPRA. [GOAT]

CAPRELLA. [LEMNIFODA.]

CAPRE/OLUS, an old name for the tendril of a vine.

CAPRI, the Roman Capræ, a rocky but beautiful island in the Mediterranean, situated under the same meridian as the city of Naples, which it immediately faces. It stands at the southern entrance of the Neapolitan gulf; it is two miles and a half from Cape Campanella, which terminates the promontory of Sorrento; about ten miles from Cape Miseno, on the other side of the bay, and rather more than twenty from the city of Naples. It is composed of hard calcareous rocks, which are disposed in two masses with a considerable hollow between them. The highest of these two masses, which is to the W., rises between 1600 and 1700 feet above the sea. It is called Anacapri, and a pretty little town upon it bears the same name. The inhabitants of Anacapri communicate with the other town and all the

east of the island by means of a steep flight of 538 steps, which is carried down the face of a precipice in a very curious manner.

The other town, which is called Capri, or The Metropolis, stands much lower, on a shelving rock towards the eastern extremity of the island: it contains from 200 to 300 small but neat houses, five or six churches and chapels, and a confined piazza or square in the middle. In 1826 the population of the island, including the two towns and the villas, or very small villages scattered here and there on the face of the rock, but almost entirely on the eastern part, amounted to about 3000 souls; a considerable portion of this number being sailors, boat-men, shipwrights, &c., were absent a good part of the year. There were two or three schools established by government. By great industry the islanders have retained and secured patches of good soil on steep hill sides and in the midst of rocks and cliffs: the cultivable parts produce most kinds of vegetables and fruits, a small quantity of excellent oil, and a considerable quantity of a light but generous wine. This wine, which is much used at Naples, is of two sorts, Capri rosso and Capri bianco, or red and white Capri. Another important item of exports consists of quails, which are annually captured at their seasons of passage in vast numbers. In former times the revenue of the bishop of Capri was almost entirely derived from the quail trade: this see is now united to the bishoprick of Sorrento.

The whole circuit of the island does not exceed nine miles; but this narrow space is wonderfully crowded with a variety of scenic beauty, remains of antiquity, and histological recollections. Extensive ruins of the villa of Tiberius, who resided a long time at Capri, are still shown, near a bold perpendicular cliff at the eastern end of the island.

CAPRIC ACID, a peculiar acid occurring with the butyric and caproic acids in the milk of the cow and the goat: its name is derived from *capra*, goat. In order to procure capric acid, caprate of barytes is first obtained, and by a tedious process; 100 parts of it are then reduced to powder, and treated with 47.5 of sulphuric acid, mixed with its weight of water. The capric acid is thus separated after long digestion, and it is then to be distilled from chloride of calcium.

Capric acid crystallizes in small needles, which liquefy at about 65° Fahr.; its specific gravity at this temperature is 0.910; it distils without alteration at a temperature above 712°. Water at 68° dissolves only about 1/100 of its weight; but alcohol dissolves it in all proportions. Its smell resembles that of the goat.

The saline compounds of capric acid are called *caprates*; no one of them is applied to any use.

According to M. Chevreul, who discovered it, capric acid consists of—

39	Equivalents of carbon	1357.9	or 74.11
29	hydrogen	181.2	9.71 100
3	oxygen	300	16.15
1	anhydrous acid	1839.1	94.21
2	water	112.5	5.79
1	hydrated acid	1951.6	100

CAPRICORN, TROPIC OF. [TROPICS.]

CAPRICORNUS, the tenth constellation in the zodiac, as a constellation, but the part of the moveable ecliptic between 270° and 300° of longitude was also so designated. [ECLIPSE.] This constellation never rises in our latitude to a greater altitude than 25°, or thereabouts (we speak of the largest stars α and β , in the horn). Around it, in the visible portion of the heaven, are Aquarius, Equuleus, Delphinus, Aquila, and Sagittarius. The brightest stars, α and β , are on the meridian at midnight towards the end of July. A line drawn through the bright stars in Lyra and Aquila will, when lengthened, not pass far from the two brightest stars in Capricornus, α and β .

The lower half of Capricornus is that of a goat, and the lower half of the fish. In some of the Eastern zodiacs it is supposed to be an alligator or sea monster. According to Herodotus, the constellation in the heavens in appearance of a goat, was that of a goat who, when the gods were about to descend from the stars in the form of various animals, was the first to appear and half fish, and half goat.

The following are the principal stars

CAPRIFICATION, the process by which the maturation of the fig is accelerated in the Levant. It is well known that fruits which have been bitten by insects ripen sooner than others, the wound appearing to act as a stimulant to the local action of the parenchyma. This is turned to account by the Greeks in the following manner, which is called Caprifigation. When the cultivated fig is preparing for becoming ripe, a quantity of the branches of wild fig trees are brought into the fig orchards and placed upon the cultivated plants. The wild figs bring with them a great number of a small insect called *Cynips Pæones*, or *Diplolepis Ficus Curica*, which fly among the cultivated figs and pierce their fruit for the purpose of laying eggs. This not only brings about an earlier ripening of the fig crop than would otherwise be obtained, but enables the cultivator to obtain two harvests a year. It is, however, said that the practice deteriorates the quality of the fruit. Caprifigation has been artificially imitated by puncturing a fig with an awl, and introducing a little oil into the wound, for the purpose of preventing its healing too soon. (De Candolle, *Physiol. Végétale*, p. 580; and Treviranus in the *Linnaea* for 1828, p. 70, tab. 1, fig. 1 and 2, in which last place the insect is figured.) This kind of caprifigation must not be confounded with another sort, of very high antiquity, that is practised with the date palm, and which has been mentioned by Herodotus (i. 193). In this latter case the clusters of male flowers from wild date trees are brought and shaken over the clusters of cultivated females, which are thus fertilized and enabled to ripen. It is obvious that the

two cases are different, although under one common term. In the fig the *Cynips* brought by the wild branches, punctures the cultivated figs and accelerates their ripening: in the palm the pollen of the wild males is shed upon the stigmas of the cultivated females, and fecundates them.

CAPRIFOLIAEÆ, a natural order of Monopetalous Dicotyledons, having an inferior ovary, opposite leaves without stipules, and a small embryo lying in a considerable mass of horny albumen. The type of the order is the genus *Caprifolium*, or honeysuckle; the genera that are associated with it in part consist of dismemberments of *Lonicera*, and in part of plants having a resemblance to them in habit. The genera most dissimilar to *Caprifolium* are *Sambucus* and *Viburnum*; but their characters are more dependent for their dissimilitude upon the shortness of the tube of their corolla and the manner in which the flowers are arranged, than upon any actual differences of organization. *Caprifoliaceæ* differ from *Cinchonaceæ* in little except the want of stipules between the leaves, and consequently there is great resemblance in their sensible properties; their bark being often astringent, their leaves sometimes emetic, and the seeds of *Triosteum perfoliatum* similar to coffee. (Lindley's *Natural System of Botany*, ed. ii., p. 247.)

[*Caprifolium perfoliatum*.]

a, flower opened to show the insertion of the five stamens; b, front and back view of anthers; c, horizontal section of ovary; d, fruit; e, the same in section; f, seed; g, the same in section, showing the embryo; h, embryo.

CAPRIMULGIDÆ. [GOAT-SUCKERS.]

CAPROIC ACID is procured from milk, by decomposing the caprate of barytes: upon 100 parts of this salt there are to be poured 29.63 parts of sulphuric acid, diluted with an equal weight of water. The greater part of the caproic acid separates. A further quantity may be obtained by the addition of a fresh quantity of concentrated sulphuric acid, equal in weight to the first. The caproic acid separated is to be digested for forty-eight hours with chloride of calcium, and then distilled.

Caproic acid is a very fluid oil; it is colourless; very inflammable; its taste is acid and penetrating; its smell resembles that of acetic acid and perspiration. Its density at 26° Fahr. is .622; it does not congeal at 12°, and boils at 212°. It gradually vaporizes when exposed to the water at 45° scarcely dissolves 1.04 per cent.; but strong alcohol dissolves it in all proportions. Its salts, which are quite unimportant, are termed *caprouses*. M.

Chemist who discovered this acid, gives the following as its composition:

24	Equivalents of carbon	917.25	or 49.46
19	hydrogen	118.50	or 6.22
3	oxygen	300.00	or 16.32
1	anhydrous acid	1335.75	or 71.99
2	water	112.48	or 6.11
1	hydrated acid	1448.23	or 100

CAPROMYS. [MURIDÆ.]

CAPROS, a genus of fishes of the section *Acanthopterygii* and family *Scomberidae*.

But one species of this genus has yet been discovered; the *Capros aper* of Lacepède, and *Zeus aper* of Linnaeus.

The characters of the genus are—body short, somewhat ovate, much compressed, and covered with small serrated scales; mouth capable of considerable protrusion. Dorsal fin emarginated (as in the dorics), but no spines at the base, nor at the base of the anal fin.

Capros aper, or the *boar-fish*, in general appearance is not unlike the dory (to which it is in fact closely allied), but, independent of other characters, may be distinguished by its mouth being more attenuated and protractile, the body being covered with scales, and the want of long filaments to the dorsal spines.

This fish appears to be most generally about six inches in length, of a pale cinnamon colour above, and silvery-white beneath. The colour of the upper part extends more or less down the sides of the body, and sometimes several orange-coloured bands are observable extending from the back downwards. The lateral line is not readily seen, excepting in recent specimens, when it is said to have a crystalline appearance.

This fish is a native of the Mediterranean, and has been found on our own coast, but very rarely; a third specimen has recently been recorded as British.

An interesting account of this fish will be found in Yarrell's *History of British Fishes*.

CAPSA. [CONCHACEÆ.]

CAPSAICUM or bird-pepper, a genus of solanaceæ plants, with the shell of the fruit fleshy and coloured, and containing a pungent principle, which also exists in its seed in great activity. On this account both the fruit and seeds of different species of capsicum are in request as a condiment, and either in the unprepared state, or ground into Cayenne pepper, form a considerable part of the stimulating vegetables used by man. In Europe the capsicum enters largely into the seasoning of food, and the preparation of pickles; and in warmer countries it constitutes one of the first necessities of life, either green or ripe. The species from which the fresh capsicums used in Europe are principally obtained is the *Capsicum annuum*, a weedy plant found wild in South America and the West Indies. This species grows from one to two feet high, forming a dark green bush with ovate or ovate-lanceolate leaves; its flowers are small and white; its fruit is extremely variable in size, colour, position, and even in quality. Red and yellow are the prevailing colours; the oblong-conical is the ordinary figure; and to hang in a drooping position is the more usual direction of the fruit. But round, ovate, and even depressed fruit is known, and many varieties constantly bear their fruit in an erect position. Most of them are too pungent for European palates; but the large red bullock's heart and yellow tomato capsicums are mild enough to be sliced with salad.

A much hotter species is the *Capsicum frutescens* or goat-pepper, a native of the East Indies, which differs from the *Capsicum annuum* in being a shrub, and in its fruit being very small. There is also a kind cultivated by the Chinese, with black fruit; and botanists recognise many others, but they appear to be in many cases mere varieties of *C. annuum* or *frutescens*.

The acid principle of capsicum has been analysed by Braconnot (*Annales de Chimie*, vol. vi., p. 122), who found it not to be volatile, to dissolve readily in water, more freely in alcohol and ether, and that it is mixed with mucilage, wax, and resin.

The capsicum is easily cultivated in this country. Its seeds, when sown in the beginning of April, the young plants are transplanted like other tender annuals, and about the end of May they are planted in the

open air under a south wall. They will readily ripen their fruit in such a situation.

The fruit or pod of several species of Capsicum is used in different parts of the world, and under different names, as a stimulating condiment with food, or externally, as a rubefacient, or internally as a powerful excitant to the nerves of the part with which it comes in contact. The *C. annuum*, or Spanish pepper, the *C. frutescens*, or Chillies, called also Cayenne pepper, and the *C. baccatum*, or bird-pepper, are chiefly employed. They are natives of the East and West Indies, South America, &c., and are of great utility, along with different articles of food, in rousing the energies of the stomach when impaired by the heat of the climate, and thereby assisting digestion. Even birds have recourse to the seeds, and many parrots and other birds die during their voyage or soon after they reach Europe for want of this natural stimulant. The pods contain two distinct principles: the one capscin, an alkaloid; the other an ethereal oil, which is the stimulating principle: it resides chiefly in the external layers of the fruit and in the seeds.

The bruised pods, or Cayenne pepper, may be employed in the form of a cataplasm as a powerful rubefacient, which in many cases is preferable to common sinapisms. It is also of great service as a gargle, either alone or in conjunction with cinchona and serpentaria in the sore throat, when threatening to run into a state of mortification, or scarlatina maligna. It may also be given internally with the same adjuncts in the same disease. In fevers, both typhoid and intermittent, it is often a useful accompaniment to Peruvian bark; and in many cases of dropsy from debility, along with iron, it is of great benefit. But it is in dyspepsia, dependent upon atony of the stomach, that it is most serviceable. Vinegar, which has acquired its virtues (Chili vinegar) is the most suitable accompaniment to all kinds of fish at dinner.

CAPSULE, a vague name given by botanists to any kind of dry seed-vessel containing many cells and seeds. It usually opens by valves.

CAPTAIN (from the French *capitaine*, which comes from the Latin *caput*, a head), in the naval service, is an officer having the government of a ship of war, and, in the army, is one who commands a troop of cavalry or a company of infantry.

In military affairs the title of captain seems to have been originally applied, both in France and England, like that of General at present, to officers who were placed at the head of armies or of their principal divisions, or to the governors of fortified places. Père Daniel relates that it was at one time given to every military man of noble birth: and adds that, in the sense in which it is at present used, it originated when the French kings gave commissions to certain nobles to raise companies of men, in proof of which he quotes an ordinance of Charles V. This must have been before 1380, in which year that king died. In the English service the denomination of captain, in the same sense, appears to have been introduced about the reign of Henry VII., when it was borne by the officers commanding the yeomen of the guard, and the band of gentlemen pensioners. Grose's *Military Antiquities*, vol. i.

The established price of a captain's commission is, in the Life Guards, 3500*l.*; in the Dragoons, 3225*l.*; in the Foot Guards, with the rank of lieutenant-colonel, 4800*l.*, in the infantry of the line, 1800*l.*; and no officer can be promoted to the rank of captain until he has been two years an effective subaltern. The full pay of a captain in the Life and Foot Guards is 15*s.* per day; in the Dragoons 14*s.* 7*d.*; and in the Infantry of the Line is 11*s.* 7*d.* per day.

The duty of a captain is one of considerable importance, since that officer is responsible for the efficiency of his company in every qualification by which it is rendered fit for service: he has to attend all parades; to see that the clothing, arms, &c., of the men are in good order, and that their pay and allowances are duly supplied. When the army is encamped, one captain of each regiment is appointed as captain for the day; his duty is to superintend the camp, the parading of the regimental guards, to visit the hospital, to cause the roll to be called frequently, and at uncertain hours, and to report everything extraordinary to the senior officer.

A high degree of responsibility rests upon the commander of a ship of war, since to him is committed the care of a numerous crew, with whom he has to encounter the dangers of

and the chances of battle. And as the floating fortress, with its costly artillery and stores, when transferred to the enemy, increases by so much his naval strength, it is evident that nothing but utter inability to prevent him from getting possession can justify the commander in surrendering. In the old French service the captain was prohibited from abandoning his ship under pain of death: and in action he was bound under the same penalty to defend it to the last extremity: he was even to blow it up rather than suffer it to fall into the enemy's power.

The pay of a captain in the navy varies with the rate of the ship, from 61*l.* 7*s.* per month for a first-rate, to 20*l.* 17*s.* for a sixth-rate. Commanders of sloops have 23*l.*, and a captain of marines 14*l.* 14*s.* per month.

From the book of general regulations and orders it appears that lieutenants of his majesty's ships rank with captains of the army. Commanders (by courtesy entitled captains) rank with majors. Captains (formerly designated post-captains) with lieutenant-colonels; but after three years from the dates of their commissions they rank with full colonels.

The rank of post-captain was that at which when the commander of a ship of war had arrived, his subsequent promotion to a *flag* took place only in consequence of seniority, as colonels of the army obtain promotion to the rank of general officers. Such captain was then said to be *posted*; but this title does not now exist.

Several petty-officers in a ship bear the title of captains. Thus there is a captain of the fore-castle, a captain of the hold, captains of the main and fore-tops, of the mast, and of the after-guard.

CAPUA is finely situated in one of the richest parts of the Terra di Lavoro, in a plain on the left bank of the Volturno, a broad and rapid river which washes its walls. It is 15 miles N.W. of Naples, on the high road to Rome, about 12 miles from the embouchure of the Volturno, and 10 from the nearest part of the Mediterranean. Being the only fortress that covers the approach to Naples by land, it is irregularly and strongly fortified. Part of the town is very well built: its oldest buildings are of the middle ages, but many broken Roman inscriptions, fragments of columns, friezes, &c., mixed up in the walls of churches and houses, point to more remote and more civilized times. The present population is nearly 10,000.

The modern city does not stand upon the same ground as the ancient, but it occupies the site of a much inferior town, called by the Romans Casilinum; and Santa Maria di Capua, a larger, more industrious, and more prosperous town than Capua itself, covers part of the ground of the extensive and once powerful city of Capua. Santa Maria is on the same bank of the Volturno, but nearly two miles higher up the river: at that point the remains of ancient edifices are very considerable. Capua was one of the Etruscan cities founded on this coast, and its old name was Vulturium. (Livy, iv., 37.) When it fell into the hands of the Samnites it took the name of Capua, either, says Livy, from Capys their leader, or from its situation in a plain. Whatever may be the true explanation of the word, the adjective Campanus (Ager) is evidently formed from Capua. [CAM-PANIA.] Hannibal spent a winter in this town during his campaign in Italy. In the course of this war the Romans formed the siege of Capua, which adhered to the side of Hannibal (Livy, xxv., 20); when the place was taken by the consuls Fulvius and Appius Claudius, the senators were put to death, about 300 nobles were shut up in prison, and the bulk of the citizens sold for slaves. Capua at this time was probably a larger and wealthier city than Rome. There is an amphitheatre which resembles the colosseum of Rome in its form, and which, though far less gigantic, is not deficient in grandeur. From this fine ruin, Mons Tifata, often mentioned by Livy, and the somewhat more distant and much grander Taburnus, the olive-bearing mountain of Virgil, present themselves with admirable effect. At the roots of the Tifata, about three miles from the town of Santa Maria, there are some copious sources of hot mineral waters, which, though some scattered marbles seem to show that they were used by the ancient Campanians as baths, are now merely made use of to turn a few mills. European man is altogether curious, is called by the people of the district, *Aschi* (the three whistles). In the outfalls of cacao, cotton, and on the roads that branch off from, as at five miles, Caserta, Naples, and Nola, there are, displaying a variety of sepulchral for

CARACCI, or CARRACCI, LODOVICO, AGOSTINO, and ANNIBALE, three of the first painters of Italy, bigmen, fellow-students, and fellow-labourers, were natives of Bologna, and founders of the Bolognese School. Lodovico was born in 1555, and was placed at an early age with Prospero Fontana to study painting. He made such slow progress, that his master dissuaded him from the pursuit, upon which he left Fontana, and thenceforth studied the works only of the great masters, for which purpose he travelled to Venice (where he became acquainted with Tintoretto) and Parma. Returning to Bologna, he found his cousins Agostino and Annibale so well inclined to his profession, for which they had evinced an early taste by scribbling sketches in their school-books,—that he persuaded their father, a respectable tailor, to leave their education to him. Agostino, who was born in 1557, had been intended for one of the learned professions; but his inclination led him to seek employment with a goldsmith, whose business he attended to for a time. He learned engraving from Cornelius Cort, and attained to such excellence, that many of his engravings are only distinguishable from his master's by the superiority of the drawing: his works in that style are highly valued. His cousin placed him with P. Fontana, and afterwards with Passerotti. He never practised painting however with any constancy, but indulged a versatile ingenuity in various pursuits connected with literature and the liberal arts, working at his easel by fits and starts.

Lodovico retained Annibale with himself. Annibale exhibited a perfect contrast to the phlegmatic calmness of Lodovico, to the accomplished fickleness of Agostino, and to the amiable mildness of both: he was rude and impatient in temper, though of so open and generous a nature, that he is said to have kept his colours and his money in the same box, both of which were equally at the disposal of his scholars. He laboured in his vocation with an unwearied and enthusiastic devotion, and a singleness of purpose which has never been excelled, perhaps not equalled. He disliked all study but that of painting, and more than once burst out into complaints against the school-like refinements and the slow proceedings of his kinsmen in their pursuit of excellence. Like Lodovico he travelled about from place to place, improving himself by all that he saw, and aiming to combine in his own works the excellencies of the great works that he studied. The three opened an academy in Lodovico's studio, which became famous for the illustrious pupils whom it sent forth.

The fame of the Caracci reaching Rome, Annibale was invited by the Cardinal Odoardo Farnese to adorn his palace with paintings. He went, accompanied by Agostino, and the two brothers were delighted and exalted by the sight of the ancient works of art, and the labours of Michel Angelo and the divine Raphael. The usual dissensions however arose, and Annibale's intolerant devotion to labour drove away his more festive brother. The Farnese gallery occupied Annibale for eight years, for which he is said to have received only five hundred crowns; a meanness of remuneration, as La Fontaine justly observes, almost incredible. He died little after this, and died in 1609. He was buried, according to his own desire, by the side of Raphael. Agostino died in 1652: Lodovico lived until 1619.

The works of the three kinsmen are principally in Bologna and Rome. The Farnese Gallery is considered the greatest work of Annibale. The Louvre contains the 'St. John the Baptist' by Lodovico and the 'Communion of St. Jerome,' by Agostino, which are respectively reckoned their best works in oil. (Malvasia.) [BOLOGNESE SCHOOL.]

CARACCIOLI [NELSON, LORD]

CARYOTACUS. [BRITANNIA.]

CARAFFA, a distinguished Neapolitan family, divided into many branches, all descended from Filippo Caraffa, lord of Spinalonga, who died in 1220. The princes of La Roccella, Sanseverino and Belvedere, and the dukes of Mataloni, Mondragona, and Andria, are all branches of the Caraffa family. There have been in the family one pope (Paul IV.), many cardinals, archbishops and bishops, one grand master of the Order of Malta, &c.

CARAGANA, a genus of papilionaceous yellow-flowered shrubs, formerly comprehended in Robinia. Several species are cultivated in gardens, but they are not much valued. They are exclusively found in Asiatic Russia, Tartary, and the north of India; one of them, the *Caragana gerardiana*, is one of the plants called *Tartarian Horse* by travellers.

CARAMANIA or KARAMANIA, a large and important part of Turkey, comprising nearly the whole of the S. coast of Asia Minor, which is described under the general head of ANATOLIA, vol. i. and under that of ASIA, vol. ii. This extensive sea-board, which, measuring from the Gulf of Iskenderoon, or Scanderoon, to the Gulf of Makri, is upwards of 400 miles long, is divided into pashaliks or governments bearing different names, and, according to Captain Beaufort, the appellation 'Caramania' is neither used by the present inhabitants nor is recognised at the seat of government. The name is not classical, for in ancient times the provinces called Lycia, Pamphylia, the two Cilicias, with parts of Caria and Phrygia, occupied the country which we call Caramania. In the middle ages, however, a kingdom or state called Karamania, from the name of Karaman, the founder of it, did exist here, and comprised all the ancient provinces which we have mentioned; but after a struggle of two centuries it was conquered by the Osmanli Turks under Bajazet II., about 1465.

The fertile and beautiful district of Adana (the Cilicia Campestris of the ancients) was ceded by the Porte to the pasha of Egypt in the treaty of peace concluded between those powers on the 4th of May, 1833. This is the best-cultivated part of Caramania. Solitude, desertion, and wretchedness reign over nearly all the rest of the long line of coast, where the frequent and splendid ruins of Grecian and Roman cities indicate a prosperity and wealth that have long been past. (Captain Beaufort's *Surrey*, 8vo. London, 1817.)

CARANX, a genus of fishes of the order *Acanthopterygii* and family *Scomberoides*, distinguished chiefly by the lateral line of the body being furnished with a series of scaly plates. These plates are horizontally keeled (especially on the posterior half of the body), and frequently terminate in a spine, an angular projection, the point of which is directed backwards. The remainder of the body is covered with small scales. There are two distinct dorsal fins; the last rays of the posterior one are sometimes but slightly connected by a membrane, or separated into spurious fins. Some free spines are placed before the anal fin. The teeth are very minute.

Several species of this genus inhabit the seas of Europe, but we are aware of only one which has occurred off the British coast. The fish, well known by the name of *scad* or *horse-mackerel*, is frequently met with on various parts of the coasts both of England and Ireland, and at times occurs in such immense shoals, that the whole sea as far as the eye can see appears alive with them.*

The size of the mackerel, to which it comes near in affinity. The body is more even in width (i. e. less tapering towards the head and tail), and is of a dusky olive colour above, exhibiting in certain lights splendid hues of blue and green: the lower part of the body is silvery white, with the exception of the throat, which is black; there is also a black spot just above the pectoral fin.

This species, like many others found on our own coasts, occurs also on those of the Mediterranean.

In some of the species of the genus *caranx* the scaly plates are observable only on the posterior half of the lateral line, and the anterior part is furnished with small scales.

Caranx punctatus of Cuvier has but a single spurious dorsal and anal fin, whilst the *C. Rotleri* (*Scomber Rotleri* of Bloch) has several.

Scomber dentus (Bloch) and one or two other species now included in this genus are remarkable for having a single range of teeth and the body of a more elevated form.

C. carangus (*Scomber carangus* of Bloch), a large species of this genus from the Antilles, weighing from twenty to twenty-five pounds, is of a silvery hue, and has a black spot on the operculum; the body is compressed, and of a somewhat ovate form; the head is obtusely terminated. This fish is good eating, whilst the bastard *carangue* (*C.*

* Mr. Yarrell, in his 'History of British Fishes,' records an instance of this nature which occurred off the coast of Glamorganshire. The account which was communicated by Mr. Biehene, is as follows:—'They were first observed in the evening, and the whole sea, as far as we could command it with the eye, seemed in a state of fermentation with their numbers. Those who stood on some projecting rock had only to dip their hands into the water, and with a sudden jerk they might throw up three or four. The bathers felt them come against their bodies; and the sea, looked on from above, appeared one dark mass of fish. Every net was immediately put in requisition; and those which did not give way from the weight were drawn on shore, loaded with spoil.' . . . 'The quantity is very inadequately expressed by numbers,—they were caught by cart loads.' As these shoals were passing us for a week, with their heads directed up ahead, we had the opportunity of noticing that the feeding time was morning and evening. They were pursuing the fry of the herring, and I found their stomachs constantly full of them.'

Guaraterobra), another which closely resembles it, but wants the black spot, is not so prove poisonous.

CARANXO MORUS, a genus of fishes of the order *Acanthopterygii* and family *Scomberoides*. [*CORYPHÆNA*.]

CARAPUS, a genus of fishes belonging to the apodal *Malacopterygians*. [*Gymnotus*.]

CARAT, KARAT. The karatium (*καρατον*?) was originally the twenty-fourth part of the *marc*, or half-pound among the French, from whom the word came: so that three carats made an ounce. Eischschmidt cites a coin of Charles VII., of an ounce weight, bearing the legend—

*D'or fin suis, extrait de flucats
Et sus fut pesant trois karats.*

The carat was a small weight used for gold and jewels, and (*Plinctor*) varied greatly in different countries. But at last it went out of use, except only in the sense in which it still exists, namely, that a carat means the twenty-fourth part of any weight of gold or gold alloy. If such a weight be all gold, it is said to be twenty-four carats fine; if one-third only be gold, it is said to be eight carats fine.

The karath occurs (*Ducange*) in an old English charter as a measure of wine; but this is the *carrada* or *carrata* formerly used as a measure of liquids, and supposed to be the quantity which could be carried in a *carrus* or car.

CARAU'SIUS. [*AUREUS* and *BRITANNIA*.]

CARAVA'GGIO, MICHELANGELO AMERIGHI, or **MORIGI**, called **DA CARAVAGGIO**, from a town of that name in the Milanese, in which he was born about the year 1569. His father worked at Milan as a labouring builder. The son derived his first love of the art, together with such knowledge as he could pick up, in the service of certain artists as a colour-grinder. In course of time he managed to go to Venice, where he studied the works of Giorgione with great success, and some of his pictures in the style of that artist are much esteemed. He afterwards went to Rome, where finding difficulty in getting employment he engaged with a trafficking artist, called Arpino, for who he principally painted flowers and fruit. This style which he commenced painting in the unsentimental style which he over after pursued. He made a reputation to study no more from artificial models, but to adhere simply to nature, such as he found it in the streets and alleys of Rome. Neglecting his early studies at Venice, he assumed a manner characterized by dark and gloomy shadows, as if he painted in a scanty twilight, as if he painted in a quarrelled over some game with a companion, whom he killed; he fled to Naples: from Naples he went to Malta, where he was made a knight: but here, too, he quarrelled with a person of rank, and was thrown into prison. Though he made his escape to Sicily, vengeance pursued him, and he was assaulted by a party of armed men, and grievously wounded and disfigured. His friends having obtained a pardon from the pope for the murder, he set out for Rome, but unfortunately, on landing, he was taken into custody by mistake, and upon being released, could no longer find the vessel which had all his property on board. Exhausted with fruitless endeavours to find the vessel and his property, he endeavoured to make the best of his way to Rome. The heat, his yet unhealed wounds, and anxiety of mind, brought on so violent a fever, that he could barely reach the *Porta Ercolo*, where he sat down upon a bank and presently expired, at the age of forty, in the year 1609. Caravaggio was rude and negligent in his person and habits; he scarcely retained a friend, and he defied all rules of civility and decency.

The principal merit of his pictures consists in the colouring, which is pure and vigorous; the tints are few, but true to nature. Annibale Caracci said of him that he 'ground flesh' (and not colour). The obscurity in which he involves his design gives it a certain air of mysterious grandeur; but his figures are replete with the unredeemed vulgarity of the models from which he studied, and the extravagance of a self-taught conceit aggravated by abandoned habits. His principal works are a 'St. Sebastian,' in the Capitol at Rome, a 'Supper at Emmaus,' in the Borghese Palace, and the 'Entombment of Christ,' now in the Louvre, which in its original place in the Chiesa Nuova was considered to eclipse the rival altar-pieces by Barocci, Guido, and Rubens.

Among the numbers of his imitators, says Lanzi, there is not a single bad colourist: Guercino and Guido, and even Annibale Caracci, are said to have profited by the study of his works. (*Redi*.)

CARAVAN, a travelling body of merchants or pilgrims, who go in company for safety and convenience. The term, which is of Persian origin (*Cārūdā* in Persian having the same signification as Caravan in English), is confined to journeys in the East, and applies more particularly to those made in Arabia, Nubia, Syria, Persia, and Asia Minor, but the practice obtains, though mostly on a smaller scale, in many other countries where the roads are insecure, and where deserts or desolate tracts of land are to be crossed.

In the East the caravans have a commercial or a religious character, and very frequently both; the greatest of them all, or those which proceed annually to the holy city of Mecca, have always trade as well as prayers in view. These caravans are regularly organized by government, and placed under the direction of officers of high rank, who assign to the different travellers their proper place in the long line of march, and see that good order is maintained. Sixty thousand men and 20,000 camels sometimes arrive at Mecca with the Hadji or pilgrim caravans. But this amount is insignificant, compared with the numbers that flocked to the holy city in other ages. It is said that when the mother of Motasem b. Ilah, the last of the Abbasides, performed the pilgrimage, in the year 631 of the Hegira (A.D. 1234), her caravan was composed of 120,000 camels. In our times, the Syrian caravan, as it is called, though it first starts from Turkey, has been the most numerous and the best regulated; yet, according to Burchardt, who saw it at Mecca in 1814, it did not consist of more than 15,000 camels. This caravan sets out from Constantinople, or rather from the Asiatic suburb Scutari, and collects pilgrims and traders all through Anatolia and Syria. During this part of the route great care is taken for the safety and comfort of the travellers: the armed forces of different pashas and local governors escort them from town to town, and the munificence of former sultans has amply provided caravan sprais (caravan-ians) and fountains of pure water by the roadsides. On arriving at Damascus, the caravan is under the protection of the pasha of Damascus, who derives both honour and profit from the charge. At this pleasant city it generally remains three or four weeks, in order to prepare for a journey of thirty days across the desert. Here also the camels are changed, the Anatolian camel not being considered fit for such a journey. When all is ready, the pasha, Damascus, or one of his chief officers, puts himself at the head of the caravan, which he accompanies to Mecca. The signal for encamping and starting is the firing of a musket. On its route across the desert, where marauding Arabs are always on the look out, a troop of horse ride in front, and another in the rear to bring up the stragglers. The different parties of travellers, who are distinguished by their province or town, keep close together, and each party knows its proper station. The usual arrangement of the hadjis is to contract with a mekowem, a man who specializes in the furnishing of animals and provisions, has his camels, tents, servants, meat, coffee, &c., and who takes upon himself all the trouble and expense for a given sum.

The Egyptian pilgrim caravan, which starts from Cairo, is regulated in much the same manner; but it is not so large, and its route, by the head of the Red Sea, and through a country where fierce Beduin Arabs are plentiful, and wells of water very scarce, is much more dangerous.

The Persian caravan to Mecca, which used to come by Bagdad through Mesopotamia and Syria, and the Mogrebim (or Moorish) caravan, which, starting from Morocco, used to travel all through Northern Africa, have both become very irregular, though many Persians, Moors, and negroes find their way to Jidda, the port of Mecca, by sea. Considerable troops of Mohammedan Indians also visit Mecca. The great Indian caravan, which started from Muscat and travelled by Nejd to Mecca, has long been given up.

When the caravans arrive at Mecca, bringing with them goods from so many parts of the world, that city presents the appearance of a vast fair. In former times there was a second great pilgrimage and fair at Medina. A caravan of many hundred merchants, all mounted on dromedaries (this was called a 'light caravan'), and preceded by their goods on the slower camels (the heavy caravan), went from Mecca to Medina; but this caravan also is on the decline.

Besides these large annual caravans, others on a smaller scale are constantly occurring in the East, where merchants and travellers going the same road wait for one another until they can form a caravan, when they generally

appoint one of their voluntary association to regulate the order of march. For further information, see Burchard's *Travels in Syria*, p. 241. Id. *Travels in Arabia*, vol. ii. from p. 1 to p. 38. In the *Faithful Account of the Religion and Manners of the Mahomedans*, &c., written about a century ago, by Joseph Pitts, an English sailor, who went from Algiers to Mecca and Medina, are several good descriptions of the caravans.

But the caravan trade is not limited to Southern Asia. The great trade between China and Russia is a caravan trade. The road runs from Peking through the great wall to Chinggan, where the goods are taken from horses and put upon camels, which are kept and let out for this purpose by the Kalka-Mongols. From Chalgan the route lies through part of the desert of Kobi to Kiachta, the great border-market for the barter of Chinese and European articles: the journey is from 70 to 90 days. Other similar lines of route exist in Russia and the countries to the east of the Caspian Sea.

Among the knights of Malta, in whose history it is continually used, the word caravan had a very different meaning. It signified a troop or corps of knights appointed by the Order to serve in any garrison, and also the crew or the crew of any of their galleys against the Turks; for such crews were called caravans, and every knight was bound by the laws of his society to make so many caravans, or, in other words, so many sea-voyages.

CARAWAYS, the ripe fruit of *Carum Carui*, an umbelliferous, weedy, European plant, of annual or biennial duration, with finely-divided aromatic leaves, white small flowers, and a fusiform root, not unlike that of a small parsnip. The seeds, as they are vulgarly called, are the furrowed halves of the ripe fruit, have a peculiar aromatic flavour, and are used as an agreeable carminative by confectioners; the roots themselves are eaten in the north of Europe.

Caraways are used in medicine as a carminative, and more extensively by the confectioners, and by the brewers' druggists to give flavour to the beer. The chief English cultivation of the plant is in Essex and Suffolk, upon old ground broken up for the purpose. As it is a biennial, it is generally sown with another plant of the same tribe called comander; and sometimes a crop of teazles (*Carduus arvensis*) is raised on the same land; the three give a very valuable return during two or three years.

Mr. Young, in his 'Agricultural Survey of Essex,' describes this mode of cultivation minutely. Some old pasture land is ploughed up in spring; if the soil is a strong loam or clay so much the better. Ten pounds of caraway seed, ten pounds of coriander, and twelve pounds of teazel seed are sown together on the newly turned-up soil, and harrowed in. As the plants appear they are carefully freed from all weeds, by repeatedly hoeing the land. The coriander is fit to be cut in July, and is threshed out on a cloth in the field. The produce is frequently twenty-four cwt. worth on an average 16s. per cwt. The next year the caraway is reaped about the same time, and produces twenty cwt. worth 12s. per cwt. In the autumn of the same year the teazles are fit to be cut. The produce of these is very various; sometimes a load is obtained worth 12s., at other times only a quarter of a load. The caraway and the teazles continue to produce for several years, provided they are kept clear of weeds; but after the third crop the return is not sufficient to be an inducement to continue them longer on the ground. The land, which would have been too rich for corn when first broken up, is now reduced to a moderate state of fertility. From this it is evident that it is only under peculiar circumstances that this profitable cultivation can be adopted.

CARBAZOTIC ACID. This acid, which has also been called nitropicric acid, results from the action of nitric acid upon a great number of vegetable and animal substances. The largest quantity is furnished by indigo: one part of this substance reduced to coarse powder is to be gently heated with eight or ten times its weight of moderately strong nitric acid. The indigo dissolves with the evolution of much nitric oxide gas. As soon as the effervescence is over, the liquor is to be boiled, and nitric acid added from time to time till the evolution of nitric oxide ceases: on cooling crystals of carbazotic acid are obtained, which are of a brilliant yellow colour; they are to be washed with cold water, dissolved in boiling water, and re-crystallized.

The pure acid is said to crystallize in equilateral triangular

lamine, the primary form being an octahedron with a rhombic base: it reddens litmus paper, and has a very bitter taste, and on this account it has long been called *baie of indigo*; when heated it fuses and softens without decomposing. If it be rapidly heated in the air, it burns without explosion, leaving charcoal: this acid is completely soluble in cold water, but much more so in hot; the solution is of an intense yellow colour; alcohol and ether dissolve it readily; chlorine and iodine do not act upon this acid, even when it is fused in these substances in the elastic state, neither nitric nor muriatic acid, nor aqua regia act upon this acid: it contains no water, and is said to be poisonous.

According to Liebig, this acid is composed of—

Carbon . . .	36.081 or 15 equivalents
Nitrogen . . .	16.714
Oxygen . . .	47.205 14

100.

The saline compounds of this acid are called *carbazotates* or *nitropicrates*. An account of them may be seen in Berzelius's *Traité de Chimie*, tome vi., p. 386.

CARBO. [CORMORANT.]

CARBO, CNEIUS PAPIRIUS, son of Carbo the Roman orator. (Cic. *De Clur. Orat.* 27, 43, &c.) He espoused the party of Marius, and was consul three times; A. U. C. 669 he was colleague with Cinna. Cinna had the administration of Italy, while Carbo took the command in Gaul. When Cinna died Carbo remained sole consul, and opposed Sulla in Italy. He procured from the senate and people a decree declaring all who joined the cause of Sulla enemies to the state. Carbo was afterwards defeated by Pompey, and was at last taken prisoner in Sicily, and brought before his tribunal. Pompey pronounced a violent invective upon him, and ordered him to be led to execution, A. U. C. 671. (Appian, *de Bell. Civ.* vol. i. p. 410.) The ingratitude of Pompey in thus treating a man who had so ably defended him in his youth, when his father's property was going to be confiscated, has been deservedly condemned by Valerius Maximus (v. 3, 5).

CARBON. This element and its combinations, act an important part in the mineral constitution of our earth. Following the system of Berzelius, the substances containing it are arranged in three groups, the first consisting of the mineral forms of pure carbon, the second of the carbonates, and the third of those carboniferous masses in which the elements are combined according to the principles of organic chemistry, and which have resulted from vegetable matter.

The first group consists only of two essentially different varieties, namely, the crystallized and the amorphous carbon. The former, as might be expected, is the purer, and is the well known gem, the **DIAMOND**, under which name it is described: the latter is always mixed with more or less foreign matter, which gives rise to varieties known as graphite or coal-blende, anthracite, and fossil coal.

The second group, the carbonates, present us with a numerous mineralogical family of the highest interest, both in a scientific and in an economical point of view. For the purpose of studying them with the greatest facility the carbonate of lime may be taken as a type, to which the whole family may be conveniently referred. This substance possesses the peculiarity of dimorphism; that is to say, it occurs in forms belonging to two different systems of crystallization, namely, the rhombohedral and the prismatic, and is called, when its crystals belong to the former, **CALCAREOUS SPAR**, and when to the latter **ARRAGONITE**, under which terms they have been already described. The chemical composition of these minerals is that of a neutral salt, being one atom of carbonic acid united with one atom of the oxide of calcium, or lime, and therefore the chemical composition of either is denoted by the symbol Ca C . But the oxide of calcium is isomorphous with the similarly constituted oxides of magnesium, barium, strontium, iron, manganese, zinc, cerium, lead, and copper; and each of these oxides occurs combined with carbonic acid in the proportion of atom to atom, some of them producing crystals isomorphous with calc spar, and others on the contrary with arragonite. But in addition to the mineral species produced by the combination of any one of these oxides with carbonic acid, an endless variety of isomorphous crystals is formed by the combination of two or more of the above carbonates, which are capable, according to the laws of isomorphism, of uniting in

any proportion, as may be seen in the varieties of calc-spar, which are known as brown-spar, bitter-spar, dolomite, where portions of the oxide of calcium are constantly replaced by the oxides of magnesium, iron, and manganese. None of the carbonates of these oxides are found however, like the carbonate of lime, to be dimorphous, and to occur crystallized both in the rhombohedral and the prismatic system; they may be divided therefore into two isomorphous groups, the one headed by calc-spar, and the other by arragonite; and it is only among the oxides of the same group that it is usual to find the one oxide substituted for the other.

The first group crystallized in the rhombohedral system consist of

Calc-spar	$\text{Ca } \bar{\text{C}}$
Magnesian or talc-spar	$\text{Mg } \bar{\text{C}}$
Manganese-spar	$\text{Mn } \bar{\text{C}}$
Iron-spar	$\text{Fe } \bar{\text{C}}$
Zinc-spar	$\text{Zn } \bar{\text{C}}$
Bitter-spar	$\text{Ca } \bar{\text{C}} + \text{Mg } \bar{\text{C}}$
Brown-spar	$(\text{Ca, Mg, Mn, Fe}) \bar{\text{C}}$

The second group crystallized in the prismatic system consists of

Arragonite	$\text{Ca } \bar{\bar{\text{C}}}$
Strontianite	$\text{Sr } \bar{\bar{\text{C}}}$
Wetherite	$\text{Ba } \bar{\bar{\text{C}}}$
White lead	$\text{Pb } \bar{\bar{\text{C}}}$

But although the minerals of these groups are classified together as being isomorphous, this word cannot be used in its strictest sense, and as denoting an exact identity of the angles of inclination between corresponding planes in the different species, as those when measured at the ordinary temperature are found to differ from each other by small but nevertheless very perceptible magnitudes. The following table of the angles in the terminal edges of the ground-forms of the principal species of the first group, and parallel to the faces of which the cleavage planes of each occur, will best show this difference. According to the most careful measurements the angles are,

For Calc-spar	105° 5'
„ Bitter-spar	106 15
„ Manganese-spar	106 51
„ Iron-spar	107 0
„ Talc-spar	107 25
„ Zinc-spar	107 40

The three angles of calc-spar, bitter spar, and talc-spar, when the chemical composition of these minerals is considered, present a very interesting and striking relation, the angle of bitter-spar being the arithmetical mean between those of the pure carbonates of lime and magnesia, while its chemical composition may be considered also as the mean of the other two, being composed of an atom of carbonate of lime united with an atom of carbonate of magnesia. That this is a particular instance of a more general law, that the increment of the angle in any compound over that of calc-spar is to the whole difference of the angles of the pure minerals, or 2° 20', in the proportion of the number of atoms of carbonate of magnesia to the total number of atoms in the compound, appears to be established by the analysis and measurements of the French mineralogist, M. Beudant, who has made several experiments for the purpose of ascertaining this fact. An example will at once render this clear. Suppose on measuring the angle of a compound of carbonate of lime and magnesia we find it to be 105° 40', which gives an increase over 105° 5' equal to $\frac{1}{2}$ of 2° 20'; according to the experiments of Beudant we should be justified in concluding that the compound consisted of three atoms of carbonate of lime to one of carbonate of magnesia.

In addition to the carbonates above mentioned, four others are known, namely, the native soda, Gay-Lussite, lazare or blue copper, and malachite, which, although containing elements isomorphous with the former, are nevertheless differently crystallized, as they are of a different chemical composition, containing water of crystallization.

The third class, all of which contain more or less evidence of their vegetable origin, with the exception of lignite, or honey-stone, are amorphous. The distinction from other mineral bodies by their combustion being usually accompanied by it may be divided into the four principal groups

mineral resins, mineral oils, mineral pitches, &c. bituminous bodies. The principal varieties are distinguished by and are described under the names of peat, coal and its varieties, brown coal, &c.; amber, honey-stone, rosins, asphaltum, naphtha, petroleum, mineral pitch, asphaltum.

CARBON, a non-metallic elementary solid body, which is widely diffused throughout nature. The purest, and at the same time the rarest form in which it occurs, is that of the diamond [**DIAMOND**]; the more common states in which it is met with are those of anthracite, graphite, and coal; but in these cases it is not free from admixture.

Another well-known form of carbon, but still impure, is charcoal, obtained from the decomposition of wood by heat.

The diamond differs so entirely in its obvious and physical properties from carbon in its more common states, that nothing less than the most decisive evidence of the identity of their chemical nature could have allowed of their being arranged together: the proof of their similarity is stated in the article **CARBONIC ACID**. According to the circumstances under which carbon occurs naturally or is artificially procured, it possesses different properties and characters: we shall therefore first briefly mention some of these forms.

ANTHRACITE (which see), consists almost entirely of carbon in the black state in which it exists in charcoal. Kilkenny coal, which is one of the varieties, leaves when burnt about 4 per cent. of ashes; a variety of anthracite found in Pennsylvania yielded—

Carbon	90
Water	6
Silica	1
Alumina	1
Oxide of iron and manganese	0.2
	99.2

The small portion of substances with which the carbon in the anthracite is mixed is to be regarded as accidental, and it is to be considered as mineral carbon nearly pure.

Graphite [**GRAPHITE**], or as it is sometimes called plumbago and black lead, is another variety of mineral carbon, and is sometimes almost pure: it contains variable quantities of oxide of iron in a state of mixture; in some cases scarcely amounting to more than 0.05 per cent.

Most of the varieties of coal differ from anthracite in containing azote and hydrogen in addition to earthy and metallic impurity; still, however, they all consist principally of carbon. [**COAL**.]

The proof that they contain the gaseous elements alluded to is, that they furnish ammonia by distillation.

There are various other mineral products which contain carbon, as bitumen, naphtha, petroleum, amber, &c., but although it exists in them in large proportions, they also contain a considerable portion of other elements, as already stated with respect to coal. Another state in which carbon occurs very largely is that of combination with oxygen, forming **CARBONIC ACID**. This acid enters into the composition of chalk, limestone, marbles, some other earthy, and also some metallic carbonates.

Charcoal has already been mentioned as carbon procured from the decomposition of wood by burning. This operation is generally conducted in pits made in the ground; sometimes however it is carried on in iron cylinders. Wood is essentially composed of carbon, oxygen, and hydrogen; by the action of the heat it is decomposed, the oxygen and hydrogen are expelled, and uniting in certain proportions form water, and also with carbon various gaseous and other compounds are formed. Among the latter are acetic acid, sometimes called pyroligneous acid, and a peculiar inflammable fluid, known by the name of pyroxylic spirit, and tar.

The remaining charcoal has the following properties: it is black, lighter than water, and full of pores, occasioned by the expulsion of the bodies volatilized. The heavier the wood from which the charcoal is obtained, the denser it is.

Charcoal, from whatever source procured, is absolutely infusible by any degree of heat however great; neither that of a mirror, the oxyhydrogen blow-pipe, nor the voltaic discharge, being sufficient to produce fusion. In its common state it is one of the worst conductors of heat known, but its power is increased after being strongly heated. Charcoal is a conductor of electricity, which is so far from being the case with the diamond, that it may be rendered electrical by friction.

Charcoal is tasteless, inodorous, and insoluble in water. It possesses the property of destroying colouring matter, especially the charcoal procured by burning bones, which is usually called animal charcoal; it is largely used for this purpose in sugar-refining.

Charcoal, in common with other porous bodies, has the power of condensing gaseous bodies; but to a greater degree than most, or perhaps any other substances: graphite, on account of its compactness, does not possess this quality.

Saussure performed experiments to ascertain these facts by plunging a piece of red hot charcoal under mercury, and introducing it when cool into the gas. He found that box-wood charcoal absorbed in 24 to 36 hours the annexed quantities of the following gases:—

Hydrogen	1.75 times its volume.
Azote	7.5 "
Oxygen	9.25 "
Carbonic oxide	9.12 "
Olefiant gas	35. "
Carbonic acid	35. "
Nitrous oxide	40. "
Sulphuretted hydrogen	55. "
Sulphurous acid	65. "
Muriatic acid	85. "
Ammoniacal gas	90. "

These effects appear to depend entirely upon the mechanical action of the pores of the charcoal, for the gases are not at all absorbed in the ratio of their affinity for carbon, but generally according to the facility with which they are condensed; and thus it is that charcoal absorbs vapours more readily than gases, and liquids than either.

Charcoal is highly combustible; it burns in the air when strongly heated, though not very rapidly; during this combustion carbonic acid is formed by the union of the oxygen of the air with carbon.

It has been mentioned that charcoal is not pure carbon, and when a quantity is burnt there always remains a portion of ashes containing a considerable quantity of carbonate of potash and some other alkaline and earthy salts, which have been taken up from the soil in which the tree grew that furnished the charcoal.

Charcoal is used not merely for combustion, but also for the important purpose of making gunpowder. It is also applied to other various well-known uses. Carbon unites with all the elementary gases to form highly-curious and interesting bodies. Its compounds with oxygen are treated of under CARBONIC ACID, CARBONIC OXIDE, and OXALIC ACID; those which it forms with hydrogen under the head of HYDROGEN; with chlorine, CHLORIDES OF CARBON; and with azote, CYANOGEN. It combines also with sulphur to form sulphuret of carbon, and it enters into the composition of several ternary compounds.

Carbon, in an impure state, or charcoal, is employed medicinally, both internally and externally. Its power of absorbing gases and moisture renders it useful in some cases, while in other cases it seems to act by some power exerted on the vital energies of the system. A few grains of vegetable charcoal taken into the stomach cause a feeling of warmth and comfort in that organ, followed by a slight increase of the heat of the body generally. A considerably large dose will occasion vomiting, and even diarrhoea. Charcoal, especially animal charcoal, possesses the power of destroying the colour, smell, and taste of a great variety of vegetable and animal substances, particularly of mucilages and oils, and of matters in which *extractive* abounds. Allowed to remain in contact with valerian, galbanum, balsam of Peru, or musk, it destroys their characteristic odour and properties.

Meat and game, too far decomposed, may be restored to a condition fit for use by the employment of finely-powdered charcoal, assisted by sulphuric acid. Water also may be restored from a tainted state by filtering it through charcoal. The interior of water-casks is charred in order to preserve the water in a pure state. Leeches, fish, &c., live better in water kept in charred vessels than in those of any other kind.

Charcoal, both from its antiseptic and vital properties, is useful in many forms of fever, especially the bilious, remittent, and intermittent fevers of warm climates, given during the interval of the vomiting of the black matter; and in yellow and typhoid fevers. It is also serviceable in dyspepsia,

accompanied with fetid breath and eructations. It is sometimes of service in ulcerations of the tongue and fauces, connected with depraved digestion. It is likewise useful in obstinate constipation, given in doses of two or three dessert-spoonsful every half-hour, or each hour, for a period of perhaps eighteen hours. In smaller doses it has been found useful in dysentery, where the motions are acid and very offensive. Externally it is a beneficial application to foul ulcers, applied either in the form of fine powder, or as a cataplasm. Persons who are troubled with excessive and strong-smelling perspirations of the feet find the inconvenience lessened by sprinkling the inside of their stockings with fine-powdered recently-prepared charcoal. Finely-powdered charcoal may also be employed as a styptic. Charcoal, especially that procured from the coco-nut farms, along with either prepared chalk, rhatany-root, kino, or catechu, perhaps the best tooth-powder which can be employed when the gums are spongy and the breath fetid. A liniment of charcoal is sometimes useful in herpes, ring-worm of the scalp, and other cutaneous diseases.

Animal charcoal, particularly that prepared from the flesh and bones of calves, given in the dose of a few grains, three or four times a day, is said to be very efficacious in removing chronic enlargements of the glands.

CARBONATE, a salt composed of carbonic acid and a base. The carbonates are an important class of salts: some of them, as the carbonates of lime and magnesia, and the metallic carbonates, are decomposed by heat; but the carbonates of potash and of soda do not suffer any alteration by exposure to it. For the various carbonates see the different alkaline, earthy, and metallic bases.

CARBONIC ACID. There are three compounds of carbon and oxygen, viz., carbonic oxide, consisting of one equivalent of each of its elements, or six parts of carbon and eight of oxygen; carbonic acid, formed of one equivalent of carbon and two equivalents of oxygen; and oxalic acid, containing two equivalents of carbon and three equivalents of oxygen.

Carbonic acid was long known and observed to exist in various forms, and to be produced in different circumstances, before its nature was understood and its composition ascertained. Van Helmont recognised it as a peculiar matter, and called it *gas sylvestre*; Hales supposed it to be spoilt common air; Black gave it the name of *fired air*, and made many curious and original experiments upon some of its compounds, showing that the causticity of the alkalis and lime depended upon its absence; Bergmann proved that it was an acid, and called it *aerial acid*; but Lavoisier first pointed out its true nature, and in consequence of his discovery it received the name of carbonic acid, which it still retains.

Carbonic acid exists largely in nature. It is in comparatively small quantity in the gaseous state in the atmosphere; it is in solution in most spring water, and in some called mineral waters to a considerable degree; but it is in solid combination that it is found in the largest quantity, forming nearly 44-100ths of all limestones and marbles, besides occurring in less quantity united with other earths and metallic oxides.

Carbon and oxygen do not appear to combine, or, if at all, very slowly at common temperatures, by direct action; but certain compounds which contain carbon, when undergoing the process of fermentation, yield a large quantity of carbonic acid. [FERMENTATION.]

It is also produced during the process of respiration; by animal and vegetable putrefaction; and by combustion, whether of oil, wax, tallow, vegetable matter, or coal.

It appears therefore that carbonic acid may be formed by the mere combustion of any substance containing carbon; but the method of forming it in purity is to ignite and burn either charcoal or the diamond in oxygen gas; and it is found, that when 100 cubic inches of oxygen have combined with as much carbon or diamond as this quantity of gas is capable of taking up by combustion, there remains precisely as much in volume of carbonic acid gas as there was of oxygen employed. Thus 100 cubic inches of oxygen, weighing 34.4 grains, combine with 12.9 grains of carbon without any alteration of volume, and consequently 100 cubic inches of this gas weigh 47.3 grains, or its density is to that of atmospheric air as 1.526 to 1. By some chemists it is hypothetically regarded as composed of one volume of oxygen gas and one volume of the vapour of carbon, condensed into one volume. By weight it consists of

2 equivalents of oxygen = 16
 1 " " carbon = 6
 Equivalent

It contains twice as much oxygen as the bases which it saturates to form neutral carbonates.

When carbonic acid is required for experiment, it is usual to evolve it by decomposing a carbonate, rather than to form it by the combination of its elements, as above described. For this purpose, carbonate of lime, or chalk, or marble, may be put into a retort, and dilute muriatic acid being poured upon it, carbonic acid is plentifully given out; and although this gas is to a certain extent soluble in water, it may be received in jars filled with and inverted in water.

Carbonic acid gas is colourless and transparent, and therefore invisible; it has an acid and slightly astringent taste; it reddens litmus paper, but the blue colour returns as the acid volatilizes. It extinguishes burning bodies, and is fatal to animals. On account of its great density, it diffuses slowly in the air, and hence it is apt to remain long in fermenting vats, old wells, &c., and has frequently produced fatal effects upon persons descending into them. Atmospheric air may however contain 1-20th of its volume of this gas, and be respired without becoming hurtful. On account of its great weight, it may be poured from vessel to vessel, as is shown by its extinguishing a taper repeatedly.

Carbonic acid, though gaseous at common temperatures and pressures, may be compressed into a liquid state, as shown by Mr. Faraday; and by the more recent experiments of M. Thilorier, it appears to have been rendered even solid. Mr. Faraday's method of operating may be seen in the *Phil. Trans.* for 1823. The liquid carbonic acid produced is limpid, colourless, extremely fluid, and refracts light less than water does. At 32° it requires a pressure of thirty-six atmospheres to retain it in a liquid state; in endeavours to open the tubes at one end, they always burst into fragments with a powerful explosion. M. Thilorier found that a jet of liquid carbonic acid received in a glass vial expanded to about 400 times its own volume, and by this produced so great a degree of cold, that one part of the carbonic acid congealed into a white powder, adhered to the glass, and retained its solidity for some minutes without pressure. It has already been mentioned that carbonic acid gas is soluble in water, and various contrivances have been adopted for impregnating water and saline solutions with it, to imitate natural mineral waters. Among these, Dr. North's apparatus is well known, and is described in most works on chemistry. At the average temperature and pressure, water takes up its own volume of carbonic acid gas, and under a pressure of two atmospheres it dissolves twice its volume and so on. The water thus impregnated becomes brisk and tart, and reddens litmus paper; when the water is boiled, the carbonic acid is expelled. Carbonic acid is detected by the properties of extinguishing flame, proving fatal to animals, reddening litmus paper, but not permanently, and giving a precipitate with lime water; this precipitate is carbonate of lime, which is re-dissolved by an excess of carbonic acid, and re-appears when that excess is expelled by heat.

Carbonic acid, though in small quantity, always exists in the atmosphere, as may be shown by exposing lime-water to the air; the proportion does not usually exceed about one 2000th of the volume of the air; it is produced by the processes of respiration, combustion, and animal and vegetable decomposition, as already alluded to.

Carbonic Acid Gas, in a state of concentration, acts upon the human system as a powerful sedative poison. Unless largely diluted with atmospheric air, it cannot be breathed, as it stimulates the glottis, or entrance to the windpipe, to contraction, which causes the person exposed to this gas to die of suffocation. But even when so far diluted as to be able to pass the glottis, and enter the lungs, it acts as a poison; and also when brought in contact with the skin (pure atmospheric air being breathed at the same time), or with the mucous membrane of the stomach. A variable quantity of carbonic acid gas exists at all times in the air, as essential to the respiration and the life of plants; but any considerable increase of this quantity is deleterious, and destructive to the life both of animals and vegetables, though plants will flourish in an atmosphere containing nine or ten per cent. of carbonic acid gas, provided they are exposed to the direct solar light, for this quantity is

poisonous to them in the shade. (Sausure.) The cause of the absence of vegetation in the celebrated poison valley of Java is the existence of a subterranean source of carbonic acid gas, and not the shade of the upas-tree, as is popularly believed.

Carbonic acid gas is evolved from the combustion of fuel, namely charcoal, and during the process of fermentation; from the coloured parts of the flowers of plants, both by night and day, and from the green parts of plants during the night; from the calcination of lime, and it is apt to be formed and accumulate in mines, particularly coal-mines, where it is termed *choke-damp*; and in old draw-wells. It also is formed or extricated by the respiration of animals, and becomes the source of disease and death when many human beings are crowded together in close, ill-ventilated rooms.

When in such a state of concentration as not to pass the glottis, it produces instant suffocation, and if the person be not immediately removed from the noxious atmosphere, death ensues. But where it is diluted with atmospheric or other respirable air in sufficient quantity to be inhaled for a considerable time, symptoms closely resembling apoplexy are produced. This last casualty is most apt to occur from sleeping in a room with a charcoal fire, which has not a proper outlet for the gas, or in a green-house with plants, or even with a few flowers in a bed-room.

When from any of these causes an individual has fallen into a state of stupor or insensibility, he is to be removed as speedily as possible into the pure fresh air, cold water should be dashed upon the face, ammonia may be rubbed upon the chest, and, if conveniences exist, he may be caused to breathe oxygen gas. Blood, but in moderate quantity, should be attempted to be procured from the arm or jugular vein, and efforts to effect this may be persevered in for hours with ultimate success.

Carbonic acid, diluted with a proper quantity of atmospheric air, has been advantageously employed, applied to limited portions of the body. Largely diluted, it has been recommended to be inhaled in the latter stages of phthisis pulmonalis, or consumption, to lessen the irritability, and remove the factor of the breath arising from the morbid expectoration. It is in such cases merely a palliative. When brought in contact with the mucous membrane of the stomach, it is often very serviceable, but if too strong, or its use is too long continued, it may give rise to alarming or unpleasant symptoms. The more speedy intoxication and headache which follow the use of the effervescing wines is due to the great quantity of carbonic acid gas which they contain. Even soda-water, if drunk in large quantity, may produce intoxication or headache. The usual form of administering carbonic acid gas is either in some of the natural mineral waters, such as Seltzer, or by disengaging it from its combination with some alkaline base, such as carbonate of soda or potash; any acid given at the same time, by combining with the alkali, will liberate the gas. A vegetable acid, either the citric, in the state of lemon-juice, or tartaric acid, is commonly employed for this purpose; but in many instances sulphuric acid is preferable. Whenever great debility, or the phosphatic diathesis, as indicated by the state of the urine, exists, the use of a vegetable acid for the object above mentioned is prejudicial. (Prout, *On Diseases of the Urinary Organs*.)

The gas thus disengaged is of great utility in allaying irritability and spasmodic states of the stomach; thus it frequently checks vomiting, either simple, or even of blood.

In the irritable state of the kidneys and bladder which prevails in a phosphatic condition of the urine, water charged with a large portion of carbonic acid gas (but without any alkali) is of double utility, both from its sedative effect and its chemical properties of dissolving and holding suspended the phosphate of lime, and preventing it being deposited in the bladder. Externally water charged with carbonic acid gas has been employed as a wash or bath in many cutaneous diseases with good effect. The yeast poultice owes its soothing influence over irritable ulcers to the carbonic acid gas which is disengaged from it. A stream of carbonic acid gas has been proposed to be directed upon cancerous sores to allay the pain, and also upon burnt surfaces. But its employment in such cases requires caution.

CARBONIC OXIDE, commonly called also oxide of carbon, was first obtained by Dr. Priestley; but its nature and composition were determined by Mr. Cruikshank. Carbonic oxide may be prepared in various modes: first, by

direct action; if charcoal be made red hot in a gun-barrel, and oxygen gas from bladders be repeatedly passed over it, the oxygen is converted into oxide of carbon. Dr. Priestley procured it by heating together chalk and iron filings; in this case the iron takes half the oxygen from the carbonic acid of the chalk, and from a compound of two equivalents of oxygen and one equivalent of carbon, the residual gas, which is carbonic oxide, is constituted of one equivalent of each.

Another mode of obtaining it, by which it is procured with the greatest facility, is to heat oxalic acid in a retort with sulphuric acid. Oxalic acid is a compound of three equivalents of oxygen and two of carbon: by the action of the sulphuric acid, it is separated into carbonic acid and carbonic oxide, which are both evolved in the gaseous state: the acid being soluble in water is dissolved, and the carbonic oxide remains nearly pure. The properties of this gas are, that it is colourless and insipid; it is but slightly dissolved by water; it is fatal to animals, and extinguishes a taper if immersed in it; but when it meets with oxygen gas it burns, and is converted, by combining with it, into carbonic acid. It has no action upon blue vegetable colours; and unlike carbonic acid also, it does not occasion any precipitation in lime water.

Carbonic oxide is composed of

1 equivalent of oxygen =
1 " carbon =

equivalent = 14

It is hypothetically considered as constituted of 100 volumes of the vapour of carbon, and 50 volumes of oxygen gas, condensed into 100 volumes. One hundred cubic inches weigh 30.1 grains: its density is therefore to that of atmospheric air as .971 to 1. When electric sparks are passed through carbonic acid gas, confined over mercury, a portion of it is converted into carbonic oxide and oxygen gases.

CARBURET, a term designating a compound of carbon with certain other bodies, as azote, and some of the metals, &c.

CARBURET OF AZOTE. [CYANOGEN.]

CARBURET OF IRON. [STEEL.]

CARBURETS OF HYDROGEN. [HYDROGEN.]

CARCASS, a shell, or hollow ball of iron, perforated in three places at equal distances from each other, within one hemisphere of the shell, and filled with a composition which burns with violence during eight or ten minutes. When discharged from a mortar or howitzer the flames issuing from the perforations or fuze-holes set fire to any building on which the carcass may happen to fall.

For the dimensions of this kind of shell, and the nature of the composition, see Spearman's *British Gunner*.

CARCASSONNE, or **CARCASSONE**, a city in the South of France, capital of the department of Aude, on the river which gives name to the department, in 43° 15' N. lat. and 2° 22' E. long., 387 miles in a direct line due S. from Paris, or 495 miles by the road through Orléans, Limoges, and Toulouse.

Carcassonne is a very antient place, having been built before the time of Cæsar, who speaks of it as one of the *ciuitates* in townships of *Gallia Ulterior* (taking that province in the limited extent which it had before he entered upon his command). What the town itself was at that time we have no information; the township is mentioned as having, in conjunction with Tolosa and Narbo (Toulouse and Narbonne), furnished several brave soldiers for the army of P. Crassus, Cæsar's lieutenant in his war with the Aquitani (*Cæs. de Bel. Gal.*, lib. vi., c. 20). Pliny and Ptolemy notice it as one of the towns of the *Volæci Tectosages*; in the Itinerary from Burdigala (Bordeaux) to Hierusalem (Jerusalem) it is mentioned as *Castellum*, a military post, a designation which perhaps indicates decay from its former prosperity. Upon the downfall of the Roman empire, it passed successively into the hands of the Visigoths, the Saracens, and the Franks. Under the last it was for some time governed by counts of its own, who contrived to render their power hereditary. Its last count ceded his states to the then King of France, Louis IX., or Saint Louis, about the middle of the thirteenth century. Before this cession, the town had suffered severely in the wars against the Albigeois, or Albigenses, for whom it was held.

Carcassonne at present consists of two parts, separated by the river Aude, over which is a good bridge. The upper

town or *cité* is on the right bank of the river, and is the most antient part. It is encircled by the old walls; its narrow and deserted streets and ill-built houses give to it a gloomy appearance. It has a castle, now in ruins (the erection of which is ascribed by some to the Visigoths), and the cathedral dedicated to St. Nazarius. This was erected about the end of the eleventh century; it is small, but handsome; the stained glass windows are admired for the beauty of the colours. The tomb of Simon de Montfort, the general of the crusade against the Albigeois, which was in this church, has been broken.

The lower town, on the left bank of the Aude, is regularly laid out with straight streets, crossing at right angles, and watered by streams of water from the river. The houses are well-built, and there are a great number of shops, many of which are handsome. The *Grande Place* is an oblong square, surrounded by regularly-built houses, and having in the middle a fountain, the design of which is sufficiently magnificent, but the execution poor; and the neglected and filthy state of which, when visited by M. Millin, formed a contrast with the general neatness and cleanliness of the city. The *Halles*, or covered market-places, are large and airy. The *Hôtel de Ville* is a building of good architecture, the theatre is handsome, the office of the prefect has magnificent gardens, and there are fine barracks and some other public buildings. The conventual buildings (we know not to what uses they have been applied since the suppression of monasteries) and the churches are also handsome.

By the census of 1832, Carcassonne had 14,872 inhabitants; the whole commune contained 17,394. The chief manufacture of the place is that of fine woollen cloths, which is carried on with great diligence. This manufacture existed here as early as the time of Louis XI. It was much increased by the patronage of Colbert, who established a manufactory in one of the suburbs of the town. The building still remains, but the establishment has been discontinued, and the manufacture is now in the hands of private capitalists. The wool is chiefly brought from Spain or from Narbonne, or Beziers; it is carded, spun, and woven in the town, and the cloths are sent to the Levant. The trade of Carcassonne is much promoted by a navigable branch from the great canal of Languedoc, or *du Midi*. Wine, brandy, and fruit are among the other chief articles of trade. Some marble quarries are wrought in the neighbourhood of the town: the marble is of various colours; that veined with red is particularly beautiful. The quay is adorned with handsome promenades, and presents a constant scene of activity. There are at Carcassonne two libraries, a high school, and a museum.

The episcopal see of this town cannot be traced higher than the sixth century with any certainty; the assertions that there were bishops here about the end of the third or the beginning of the fourth century is very disputable. The diocese comprehends now the department of Aude, and the bishop is a suffragan of the Archbishop of Toulouse, and Narbonne. The *arrondissement* of Carcassonne comprehends a population of 90,658 persons.

The district of which Carcassonne was formerly the capital took from the town the designation *Carcasséz*. Notwithstanding the heat of the climate, and the consequent desirableness of shade, there are few trees except along the banks of the canal of Languedoc; the inhabitants allege the value of the land as a reason for their unwillingness to plant trees, or even allow them to remain. Fabre d'Églantine, member of the convention, guillotined at Paris in 1793, was a native of this town.

In the neighbourhood of the town is the relic of a column of greyish stone, bearing an inscription to M. Numerius Numerianus Cæsar; but as the whole of the inscription has not been certainly interpreted, it is not known by whom or on what occasion it was erected. There is also a remarkable aqueduct-bridge of three arches, by which the Canal de Languedoc is carried over the river Fresquel, which runs to Castelnaudary. M. Malte Bran seems to have confounded these two structures, making of them a triumphal arch on the banks of the Fresquel to the honour of the Emperor Numerian.

CARCHARIAs, a genus of fishes of the shark tribe. [SQUALIDÆ.]

CARCINUS. [CRAB.]

CARDAMOMS, the aromatic capsules of different species of *AMOMUM*. The sorts known in the shops of

Europe are the large, the middle-sized, and small, the clustered or Malabar cardamoms, and the grains of paradise, or Mellagetta or Malagueta pepper.

Large cardamoms are supposed to be the seeds of *Anomum angustifolium*, a Madagascar plant, with a remarkably strong, but pleasant and aromatic odour.

Middle-sized and small cardamoms are believed by Fée to be both produced by *Anomum cardamomum*, a native of Sumatra, and other islands to the eastward of the Bay of Bengal.

Malabar cardamoms, which are the best sort, and those in the most extensive use, are produced by *Anomum repens*, the *Eleitaria* of Maton, and the *Alpinia cardamomum* of Roxburgh. This is a native of the mountainous part of the coast of Malabar, especially among the western mountains of Wynad, where it is called by the natives the *Ailum* shrub. For its cultivation, see Roxburgh's *Flora Indica*, vol. i, p. 72; and the *Transactions of the Linnean Society*. It is believed to be the *anomum* of Theophrastus, and constitutes at the present day the most esteemed of the condiments employed by the Turks, Persians, and other eastern nations, entering into all their sauces, pillaus, curries, &c.

Grains of paradise, called also Mellagetta or Malagueta pepper, are the fruit of *Anomum granum paradisi*, a native of Ceylon and Madagascar. Its qualities are similar to those of ordinary cardamoms, but inferior. It is probable that the seeds of some other species of *anomum* would also serve as substitutes for cardamoms, but they have not been much inquired into. *Anomum aromaticum* is mentioned by Roxburgh as being so employed by the natives of the eastern frontier of Bengal; *Anomum maximum* also yields a coarse description of the drug.

CARDAN, JEROME. To give any great detail of the life and writings of this singular union of genius and folly would require considerable space. We must therefore confine ourselves for the most part to those circumstances in regard to which his name is principally mentioned in modern writings.

On the life of Cardan the authorities most in use are—1. His own treatise *De Vita Propria*. Works, vol. i.—2. G. Naudæus 'Judicium de Cardano,' 1643. The most accessible accounts of these are in 'Bayle's Dictionary,' article 'Cardan'; and in Teissier, 'Eloges des Hommes Savans,' vol. iv, p. 97.

The works of Cardan were collected under the title of 'Hieronymi Cardani Opera omnia, curâ Caroli Spornii, Lyons, 1663, in ten volumes, folio. The following list of works, so long as it may appear, is perhaps the shortest mode of touching on many points which require only the briefest notice. In all, the date begins the title.

1539. Card. Cassilionei Practica Arithmetica, &c. Milan.—1541. Aphorismi astronomici. Ulm.—1542. De Consolatione. Venice.—1544. De Judicis Genturum exemplis illustratum. Nuremberg.—1545. Ars Magna, &c. Nuremberg.—1545. De Malo recent. Medic. medendi usu. Venice.—1545. De Animi Immortalitate. Venice.—1547. De Supplemento Almanach. Nuremberg.—1547. De Genitura, Revolutionibus, &c. Nuremberg.—1550. De Rerum Subtilitate. Nuremberg, (again in 1557.)—1553. An Baln. Articulari Morbo competat. Venice.—1454. In quadripart. Cl. Ptolemæi. Ejusdem Genturum xii. Basle.—1557. De Rerum Varietate, lib. xviii, folio. Basle.—1559. In Hippocratem de Aere, &c. Oratio de Medic. Insectis. Basle.—1559. Opusc. Artem Med. exercent. utilissimæ. Basle.—1561. De Utilitate ex Rebus Adversis capiendâ. Basle.—1562. II. Card. Somniorum Synesiorum, libri iv. Basle.—1563. De Providentiâ ex Anni Constitutione. Bologna.—1561. Comm. in vii. Particulas Aphorism. Hippocratis. Basle.—1564. Ars Curandi parva. Basle.—1565. De Simpl. Medicament. Noxâ. Paris.—1566. De Methodo Medendi. Paris.—1566. Anti-Gorgias. Basle.—1570. H. Card. &c. de Proportionibus Numerorum, Motuum, &c.... Præterea Artis Magnæ sive de regulis Algebra, liber unus, &c.... Item, de Alizâ Regulâ liber. Basle.—1573. Examen 22 Aegrotorum Hippocratis. Rome.

We have chosen this list as containing all we can certainly ascertain to have been published during his lifetime. We have found the dates mostly in old catalogues, and it is very possible that several may be reprints. The list of his works is of considerable length; but many were not published until after his death; and some not till the collection in ten volumes, already mentioned, was

published. He states of himself that he had printed 126 books, had written 40 more, and that 60 authors had cited him.

Jerome Cardan was born at Pavia in the autumn of 1501: his father was a physician and lawyer at Milan. From two circumstances mentioned by himself, namely, that his mother and father did not live together, and also that the former endeavoured to procure a miscarriage, it is presumed that he was illegitimate. At twenty years of age he studied in the university of Pavia; at twenty-two he taught Euclid in the same place. He went to Padua in 1524, and was there received doctor in medicine in 1525. He was successively professor of mathematics or of medicine at Milan, Pavia, and Bologna, and was imprisoned in the latter place (but for what offence is not stated) in 1570. Having obtained his liberty, he left Bologna in September, 1571, and went to Rome, where he was admitted into the college of physicians, and received a pension from pope Pius V. He died after Oct. 1, 1576, and probably not long after, but when is not well known. He was unfortunate in his family, which consisted of two sons and a daughter. The elder poisoned his wife, and died by the hands of the law; Cardan protested against the sentence, and rested his son's justification upon the conduct of the wife, who, he affirms, had made his son believe she was a woman of good fame and fortune, being neither. It is an evidence of the extreme vanity of his character, that, not denying the fact for which his son suffered, he left on record his belief that the judges, in passing the sentence, had no other object than to deprive him of life or reason. The younger son turned out badly, and was disinherited by his father. His daughter, according to his own account, never caused him any other vexation than the payment of her marriage portion. The treatise 'De Utilitate,' &c. was written on the death of his eldest son.

If Cardan had left nothing but writings on astrology, mathematics, medicine, or morals, he would have passed among the rest as an eccentric genius, with a full share of all the folly and mysticism which pervaded the philosophy of his day. It is to his own account of himself that we are indebted for the quantity of description and speculation relative to his personal character which is found in all biographies. There may be in this production a touch of the insanity which delights in accusing itself of crimes, or in exaggerating its foibles: as it is, and taking the character of Cardan as he has given it himself, we see a man—of unequalled self-conceit, as when he says his book of logic (written in seven days, but hardly to be understood by any one else in a year) has not a letter either of omission or superfluous; and that he is born to deliver the world from a multitude of errors: of little benevolence, as when he avows that his greatest delight in conversation is to say things which he knows will be disagreeable to his hearers: of no veracity, as witness his assertion that he acquired a perfect knowledge of Greek, Latin, French, and Spanish in twenty-four hours from an edition of Apuleius: of violent temper, instanced by his striking one in the face with a dagger whom he discovered to be cheating him at play; and of little honesty, as evidenced by his justification of his refusal to return a pledge, namely, that it was deposited in presence of no witness. He was also a superstitious free-thinker; attached to his religion, but disposed to treat it in his own way, to an extent which made a worthy divine who claimed, we suppose, to be the adjutant-general of heretics, call him the 'chief of the hidden Atheists of the second class.' His refusal to accept an advantageous settlement in Denmark, on condition of apostatizing, ought to establish his right to some principle. His four gifts—1. the power of throwing his soul out of his body (for his words can mean nothing less)—2. his faculty of seeing whatever he pleased with his eyes, 'oculis, non vi mentis'—3. his dreams, which uniformly and on every occasion foretold what was to happen to him; and—4. his finger nails, which did the same thing; to say nothing of his astrology, his good demon, &c. &c.—establish his claim to be the chief of the visionaries 'of the first class.' Bayle has drawn the distinction between him and other men of equal talent with some point: he says that 'nullum magnum ingenium sine mixturâ dementiæ' is not a maxim which includes Cardan; for that with him the folly is improved by talent, not the talent adulterated by folly.

It would hardly have been worth while to have entered into the preceding detail, if Cardan had been a common

man. As a physician, his reputation extended through Europe, both as a practitioner and a writer. In 1552 he went to Scotland to the assistance of Hamilton, archbishop of St. Andrew's, whom he cured: in the memoirs of Melvil the fact is stated, and Cardan is mentioned by name, with the addition that he was an Italian magician. His medical writings have procured him no lasting reputation; those who follow such pursuits seem to have tacitly consented that Cardan shall be left to the mathematicians; and it is to his discoveries in algebra that he must be considered as entitled to a prominent place in biography. Before proceeding to consider him in this character, we shall only state that De Thou, who knew him personally, and records that he always dressed in a different manner from the rest of the world, says that it was commonly believed his end arose from starvation, voluntarily undergone, that he might not outlive the time which he had predicted for his own death. This story has been frequently copied, as if the fact had been positively asserted by the historian, whereas he only speaks of a rumour.

The *Ars Magna*, published in 1545, contains the extensions which Cardan made in the solution of equations. Algebra was then an art contained not in formulæ but in rules, and extended no farther than the methods of solving numerical equations of the second degree. We shall not here enter into the celebrated dispute between Cardan and Tartaglia, further than to specify the part taken by the former. When he was informed of the solution of cubic equations, which Tartaglia had discovered, he applied to the latter, March 25, 1539, and requested he would communicate his method, which Tartaglia declined, intending to reserve the same for the work which he published afterwards in 1554. Cardan then swore 'upon the Holy Gospels, and the faith of a gentleman,' that he would not only not divulge the secret, but would engage to write it in such a cipher as no one should be able to read, in case of his death. Tartaglia, upon this assurance, communicated his method. This detail rests upon the authority of Tartaglia himself (*Questi et Inventioni*, folio 120), but is amply confirmed by Cardan's subsequent letters, and was never denied by him. Notwithstanding his word thus pledged, Cardan published these methods in his *Ars Magna* (1545), giving the credit of them, indeed, to Tartaglia, but concealing the promise he had made.

The communication made to Cardan amounted to the solution, without demonstration, of $x^3 + ax + b = 0$, in the cases where a and b are, one or both, negative. Cardan himself supplied the demonstrations, showed how to reduce all equations of the third degree to the preceding form, and how to extract the cube root of the binomial surd quantities which the well known solution involves. He may be said to have arrived, in detached and isolated theorems, at as much, relative to equations of the third degree, as could afterwards be established, in the time of Des Cartes, for equations of all degrees. He was the first who considered negative roots, and comprehended the nature of the connexion between them and the positive roots of other equations; and he even gave the first idea of a method of approximation.

The algebra of Cardan, owing to the want of general symbols, is difficult to read; and Montucla, biassed perhaps in favour of his countryman Vieta, has somewhat underrated his merits. On the other hand we have Cossali (*Origine, &c. dell' Algebra*, Parma, 1797), whose object it seems to be to discover something like modern and symbolic analysis in the obscure and verbal rules of the Italians of the sixteenth century. If this learned and estimable writer be considered as holding a bribe for Tartaglia, Cardan, and Bombelli, his work may be highly useful. For instance, when he shows, by collecting the various cases propounded by Cardan, that the latter had all the elements, which, if put together, would have been the celebrated rule of signs of Descartes, and thence claims that Cardan was in possession of that rule so far as equations of the third degree were concerned, he forgets that Cardan neither did nor could put those elements together. And when he attributes a symbolic (or as it was technically called, a specious) notation to Cardan, because the latter sometimes uses a letter to stand for a number in his general enunciations, he does not remember that Euclid has a prior claim, if in that circumstance merely, consists the leading feature of the method of Vieta.

There is in the algebra of Cardan considerable power of

developing the details of his subject, and of explaining the modifications presented by solutions, but not much inventive sagacity. He states himself, that he was originally prevented from attempting the solution of cubic equations by the simple assertion of Lucas di Borgo, in his work on algebra, that the solution was impossible, though Cossali has shown that, had he even read that author with attention, he would have seen that the assertion was not meant to apply to more than algebra as it then existed. In the case of biquadratic equations, he attempted nothing himself, but requested his pupil, Ludovico Ferrari, to undertake the investigation; who accordingly produced the reduction now known by his name, and which was published by Cardan. But if we take the whole extent of the *Ars Magna*, it is sufficiently obvious that Cardan would have been an analyst of considerable power, if he had lived after Vieta.

There is in the second volume of Dr. Hutton's *Tracts* an account of the *Ars Magna*, the most complete of which we know in English.

CARDIGAN, a sea-port and borough town, the capital of Cardiganshire, is about 200 miles direct distance W.N.W. of London, and 234 miles by the roads. It is called Aberteifi by the Welsh, from its standing upon the banks of the river Teifi; about three miles from its mouth. Cardigan, in conjunction with Aberystwith, Lampeter, and Adpar, returns one member to parliament. Adpar, a small village once disfranchised, has been restored as a contributory borough. The limits of the borough of Cardigan, formerly co-extensive with the parish of St. Mary, were extended by the Reform Act: they now include the whole of the old borough, together with Bridgend Hamlet and Abbey Hamlet, in the parish of St. Dogmaels in Pembrokeshire. By the same act the limits of the other contributory boroughs were enlarged. In a charter granted to Cardigan by Henry VI. several previous grants and charters are recited, the oldest of which is in the reign of Richard I. Cardigan first rose into a town about the time of the Norman conquest. The foundation of its castle is ascribed to Gilbert de Clare, about 1160. The first fortifications lasted only a short time, as the continual struggles between the Welsh and their Norman invaders for the possession of this post, which the mouth of the river rendered important, and the various success that attended the contest [CARDIGANSHIRE] caused the frequent damage or destruction of the castle, which was however always restored by the victors soon after they had obtained possession of it. The two towers and the wall now standing are probably the remains of the fortifications erected by Gilbert Marshall, about the year 1110. Edward I. resided here for a month while settling the affairs of South Wales.

The castle stands in a commanding position above the river, which is here crossed by an ancient bridge. Giraldus Cambrensis states the Teifi to have been the last British river in which beavers were to be found. There was a priory here, which is stated by Leland to have contained eleven black monks, and to have been a cell to Chertsey. A small but strong camp, called Hen Castel, is situated on the banks of the Teifi, a little below the town. The local government is administered by four aldermen, one of whom is mayor, two bailiffs, and twelve common councilmen. All the streets are narrow excepting one, the principal thoroughfare of the town, at the end of which stands the county gaol, which was erected by Mr. Nash in 1793. A handsome county hall was built here in 1764. The church, whose tower at the west end is of more modern date than the chancel, is dedicated to St. Mary. The supply of water in this town was extremely deficient, until a reservoir was built by subscription in the upper part of the town, from which the requisite pipes have been laid. Coal is imported coastwise, and peat is used by the lower classes of inhabitants.

Cardigan contains the chief custom-house for the port of Cardigan, which extends four to five miles beyond Fishguard on the S., and about twenty-four miles to the N., so as to include Aberayron. The harbour is greatly obstructed by a bar, and is dangerous in winter. Ships of 300 to 400 tons can come up to the bridge in spring tides; but the general trade is confined to vessels of from 20 to 100 tons. The registry of vessels in this port is considerable. At present (1836) there are 280 ships of every description, from 20 to 270 tons, their average being about 60 tons; these are employed in the Irish, foreign, and coasting trade. The imports are chiefly coal, culm, limestone and deals; the

exports, oats, butter, and slates. No manufacture of any importance is carried on here. The population in 1831 was 1149 males; 1516 females; total 2795; 273 families employed in trade and handicraft; 20 families employed in agriculture.

The number of inhabited houses was 560; the town seems to be

with 214. 10s. 6d., in 1793, by Lady Aber Marles; it now contains about thirty children. There is a national school, with about eighty scholars; a girls' charity-school, supported by voluntary contributions, contains near fifty, and commercial schools about sixty pupils.

termined, amounted to 2267. 12s. The poor's expenses of the year ending Easter, 1835, were 9047. 8s. 9d.

CARDIGANSHIRE, a maritime county of South Wales, bounded on the N. by the counties of Merioneth and Montgomery, on the E. by Radnorshire and Brecknockshire, which are for the most part separated from it by the rivers Claerwen and Towy, on the S. by Pembrokeshire and Carmarthenshire, from which in three-fourths of its length it is divided by the river Teify, and in part by a stream called the Dorthie. The Irish sea forms its boundary on the W. Its greatest length from N.E. to S.W. is about forty-six, and greatest breadth from E. to W. near thirty-five miles. The length of sea-coast is about forty-two miles. The area is 675 square miles. In 1831 its population was 64,780, being an increase of 21,424, or about one in three during the thirty previous years.

The S.W. district of Cardiganshire is level, as also is the neighbourhood of Aberayron, and several other tracts near the coast; in general, however, the surface is mountainous, especially in the northern and eastern parts. The highest lands are rugged, bleak, and barren; covered with ling, rushes, and heather, where the peat is not too wet, or the ground too stony to suffer them to grow: those that are somewhat lower afford pasture for the little hardy sheep of the country, the property of the small farmers, whose dwellings are, for the sake of shelter, placed in the narrow valleys beneath. The proportion of unenclosed to inclosed lands is very large. An anecdote related by Mr Malkin in his account of Cardiganshire is an apt illustration of the condition of its surface. An auctioneer who was endeavouring to sell a considerable estate, after having explained the value, &c., of the property, thus addressed the company:—"And, gentlemen, there are 10,000 acres not mentioned in the particulars of the estate, which will be thrown into the bargain to the purchaser." It has been calculated that the area of the inclosed lands does not exceed that of the uninclosed by more than 25,000 acres.

A part of Plinlimmon is situated in the N.E. part of the county: this mountain and Tregaron Down, Talsarn, and Capel Cynon are the most elevated summits in Cardiganshire. Their heights are—Plinlimmon, 2463 feet; Talsarn, 1143; Tregaron Down, 1747; Capel Cynon, 1046. The sea-coast, in its N. and S. extremities, is flat and sandy; towards the centre of its line the hills terminate abruptly, and the beach, from which, on account of its shelving rapidly, the sea retreats but little at low tide, is chiefly formed of shingle. The principal rivers are the Teify, which rises in Llyn Teify, a small lake on the eastern border, and abounds with salmon, of which a large quantity is carried to distant markets: the Towy, the Claerwen, the Ystwith, and the Rhydol, which rises in Plinlimmon. The two latter fall into the sea at Aberystwith. The Arth, the Ayrn, the Wirral, and the Lery are also considerable streams. The roads (which carry the whole traffic of the county, for there is neither canal nor rail-road in this district) have of late years been much improved. An entirely new line of communication with Radnorshire, which in part of its length is used by travellers to Llanidloes and Newtown, has been of great benefit to Aberystwith. A mail was established in 1835 from Aberystwith along this road to Rhayader, and thence to Hereford and Cheltenham, which has accelerated the delivery of London letters in a large part of Cardiganshire nearly twelve hours. The other principal roads lead from Aberystwith to Machynlleth, from the same place to Cardigan and Lampeter, and that from Tregaron through Lampeter and Newcastle Emlyn to Cardigan. At a few miles N.E. of Tregaron are situated several small mountain-

lakes, which are abundantly stored with fish. The chief are Llyn Teify, Llyn Gynon, Llyn Egnant, and Llyn-rudon-vawr; these have much wild beauty, which is however far exceeded by the celebrated water-falls of the Mynach at the Devil's bridge, the falls of the Rhydol at Hayad, and the rapids higher up that stream, in the neighbourhood of Pont Erwydd. The climate of this county is in winter very rough, the winds are violent, and the snow frequently remains on the mountains till late in the spring; in summer however and in autumn there is a light dry wholesome air, which is extremely pleasant.

The county of Cardigan chiefly consists of hard slaty strata, belonging to the transition series, and destitute of organic remains. They lie immediately under the lowest member of the Silurian system, recently described by Mr. Murchison as occupying the neighbouring counties. No coal is known to exist in this district, nor can it be expected that any will ever be found in strata belonging to so early a geological period; neither is any limestone found within the county.

The soil of this county is for the most part unfavourable to cultivation; in the mountainous districts it is thin and cold, and yields a small produce of oats, barley, and potatoes; rye is also sown in small quantities. Near the sea-coast, especially on the flat loamy tract between Aberayron and Llanrysted, wheat is cultivated successfully; large crops of barley are raised on lands manured with sea-weed, and potatoes are grown in abundance.

The system of husbandry, as well as the rude implements that are used, admit of considerable improvement.

The prevailing breed of cattle is small and hardy, in colour for the most part black or brindle; dairy-farming is not uncommon, and butter is made in considerable quantities. The horses are small but compact, and though frequently supplied with only scanty fare, are capable of drawing considerable weights in one-horse carts, which throughout the county are in general use, waggon being seldom if ever seen. The sheep are neither well-formed nor fine in the fleece; but their endurance and constitution adapt them admirably to the exposed hills on which they pasture, and from which they are seldom driven down, the ewes in the yearning season excepted. They do not fatten readily, and are so small as frequently not to weigh more than 10 lbs. a quarter: the mutton is excellent both in grain and flavour. A considerable quantity of pigs and poultry is reared, and eggs in great numbers are collected from the cottages and farm-houses, by persons who convey them weekly to distant markets.

The farms are let on a yearly tenure, at from 12. 10s. to 37. an acre near the principal towns, about 17. 1s. on many parts of the coast, and from 6s. to 15s. in the more mountainous parts. With nearly all farms is let a right of pasturage on the hills for a given number of sheep, which often forms the principal source of profit. Their size varies from 40 to 150 acres; in the best districts some are yet larger. The farmers too frequently rent more land than their capital enables them to cultivate properly, and it is not unusual for them to exhaust the land and employ insufficient labour. The fences are frequently made with alternate layers of turf and stones, built up as walls, without bushes growing upon them. The cottages are generally very bad; it is usual to whitewash their roofs as well as the walls.

Cardiganshire is divided into five hundreds—Genewr Glynn, Ilar, Moyddyn, Penarth, and Troedyraur. Cardigan Island, an extra-parochial tract of pasturage of about forty acres extent, situated at a short distance from the mainland, at the mouth of the Teify, forms a part of Troedyraur hundred.

There is an accepted tradition that there was formerly, in addition to these five hundreds, a sixth, called Gwaelod, or 'the Low Land,' which has been encroached upon by the sea. Portions of trees are found at a considerable distance from the shore, a fact which, combined with the circumstance that the rocks run in a serpentine direction about twenty-two miles from the Merionethshire coast, between Harlech and Barmouth, tends to confirm the above opinion. These hundreds are divided into sixty-eight parishes, which contain five mark & towns—Aberystwith, a seaport in Genewr Glynn hundred; Lampeter, in Moyddyn; Cardigan and Newcastle-Emlyn, in Troedyraur; and Tregaron, in Penarth. Of these Cardigan and Newcastle-Emlyn are on the river Teify, and Tregaron and Lampeter within a short distance of its banks. Cardigan, Lampeter, Aberystwith,

and Adpar are corporate towns. Next in size to the market-towns are the villages of Llanbadarn Fawr, Llanarth, Llanrysted, Aberporth, and Abera. The benefices throughout the county are of very small value; nearly all are below 200*l.* a year, and a large proportion below 100*l.* The chief residences are Havod, belonging to the Duke of Newcastle; Gogerddau, Nantcoes, and Crosswood, the property of Lord Lisburn.

The mines, which in former times were both extensively and profitably worked, are now of comparatively small value. At Talbont the ore is nearly exhausted; at Cwynystwith the lead mines are not productive, and the copper ores have ceased altogether to be worked. Four persons only are enumerated as smelters in the population returns of 1831. There are several slate quarries in the neighbourhood of Aberystwith, but the slate is not of good quality. As there is no coal in the county, peat, being abundant, is the fuel chiefly consumed. The manufactures of this district are unimportant, being confined to the weaving of a small quantity of flannel and coarse woollen stuffs. Gloves are also made in the neighbourhood of Aberystwith and Tregaron. Oats, butter, and slates are exported. The decks of some of the vessels engaged during the summer in bringing lime or limestone from Pembrokeshire, or otherwise in the coasting trade, are taken off in autumn, and they are used as fishing-boats. The principal imports are coal from Liverpool, culm from South Wales, Pembroke limestone, and Menai and American deals. The harbours are extremely exposed, and the bars at Cardigan and Aberystwith are great impediments to navigation. The supply of fish is variable, for except in fair weather the boats do not venture out to sea.

Cardiganshire is wholly in the province of Canterbury and diocese of St. David's. One member is returned to parliament for the county, another for the contributory boroughs. The assizes are held at Cardigan, where the judge named for the South Welsh circuit comes the third in rotation on his way from Pembroke to Carmarthen. The county polling places are Cardigan, Lampeter, Aberystwith, and Tregaron. The Easter quarter-sessions are held at Lampeter, at other times at Cardigan or Aberystwith.

The name Cardigan is derived from 'Caredigion,' which signifies the territory of Caredig, the first king of this district, who was succeeded by a long line of princes of whom little is known until the reign of Rodri Mawr, or Roderick the Great, who in the year 843 became by inheritance and marriage the king of all Wales. At his death Roderick divided his dominions into three parts, in each of which he had built a palace, and bequeathing to each of his sons a share, appointed the third prince umpire over the quarrels of any other two. Cardiganshire became the property of Cadell, who shortly after his father's death seized upon his brother Merfyn's portion, which caused the eldest brother, Anarawd, to lay waste the county of Cardigan. Cadell died in 900. After his time Cardigan became a lordship under the princes of South Wales. Gwaethvoed Vawr, its first lord, was succeeded in 950 by his son Cedivor. In 952 Cardiganshire was again laid waste by two North Welsh princes, who claimed it as their possession. Cedivor was probably a tributary to Owain, son of Howell Dda, who became governor of Cardiganshire at his father's death. The lords of Cardigan cannot be traced regularly after this period. In 986 Meredith usurped the territory, but in 987 was much harassed by the Danes, who destroyed St. David's, Llanbadarn, Llanrysted, and several other religious places. Edwin, the lawful heir, in 989 procured an army of English and Danes, and obliged the inhabitants to own him their sovereign. In 1038 Gruffydd, prince of North Wales, came into Cardiganshire, burnt Llanbadarn Fawr, and afterwards compelled all South Wales to swear allegiance to him. In 1071 Cardiganshire was again plundered by the Danes. About 1092 the Normans landed here, and Roger Montgomery, earl of Arundel, did homage to William Rufus for the lordships of Cardigan and Powis; but when King William returned to Normandy, the Welsh, commanded by the princes both of North and South Wales, entered Cardiganshire, and destroyed the Normans, their castles, and fortifications. In 1097 Cadwgan, who had been deprived of his possessions in South Wales, regained Cardiganshire, with part of Powis. Upon a dispute with Cadwgan Henry I. gave permission to Gilbert Strongbow, earl of Strigill, to seize his territories. Gilbert raised a strong force, soon reduced Cardiganshire, and built the castles of Aberystwith

and Cilgerran. In 1114 Gruffydd, the son of Rhys ap Ieudor, having gained many victories over the Normans, the inhabitants of Cardiganshire, fearing that his next expedition might be against them, offered the government of their country; this was accepted by Gruffydd, who with his whole army was soon after cut to pieces by Gilbert Strongbow and the Normans. To the joy of the Welsh, Gilbert did not long survive him. In 1135 Cadwalader and Owen Gwynedd, the sons of the prince of North Wales, with 6000 foot and 2000 horse, being joined by two chieftains from the South, determined to extirpate the Normans. They overran the country as far as Cardigan, and were victorious in an engagement with Stephen, the governor of the place, whose army, composed of Normans, Flemings, and English, lost more than 3000 men. About the year 1137 Owen Gwynedd a second time invaded Cardiganshire, which it seems then belonged to his brother Cadwalader. He entered it a third time, and burnt Aberystwith Castle in 1142. There were repeated engagements between the Welsh and Normans in 1144; and in 1148 Cadwalader built a castle at Llanrysted, which afterwards sustained an obstinate siege. The disturbances among the Welsh continued with little intermission until 1171, when King Henry II. gave Cardiganshire with other territories to Prince Rhys, the last prince of this district. In 1176 Rhys gave a great entertainment at Christmas in his castle of Cardigan; several hundreds of English, Normans, and others were there. All the bards of Wales were present, answering each other in rhyme. Gruffydd Rhys's son became lord of this county in 1196; he was soon involved in a dispute with his brother Maelgwyn, who seized his territory, and threw him into prison. In 1207 this cruel usurper, fearing an attack from Llewelyn ap Iorwerth, prince of North Wales, demolished his castles of Aberystwith, Ystradmeiric, and Dmeith; nevertheless Llewelyn entered Cardiganshire, and having rebuilt Aberystwith Castle gave it to Rhys and Owen, the sons of Gruffydd ap Rhys, and nephews of Maelgwyn. Maelgwyn swore allegiance to the English, and procuring by these base means a large army of English and Normans, gave battle to his nephews, but was conquered and slain. King John having already subdued the rest of Wales, compelled Rhys and Owen to give up their lands, and do homage to him; he also fortified and garrisoned Aberystwith Castle, but did not long retain his possession. In 1215 Llewelyn entered Cardiganshire and took Cardigan Castle, and in the following year partitioned out and gave South Wales to different chieftains, who acknowledged his superiority. Llewelyn afterwards seized Aberystwith Castle in addition to that of Cardigan, where he sustained sieges from, and in his turn besieged, the English, who having obtained possession were in 1231 conquered by Maelgwyn the younger.

In 1238 Llewelyn summoned all the Welsh lords and barons to Ystradflur, where each swore fealty to him; and did homage to his son David, whom he named his successor. But David was not to enjoy tranquillity; Gilbert Marshall, earl of Pembroke, besieged, took, and garrisoned the castle of Cardigan. In 1270 Maeloe did homage to Llewelyn ap Gruffydd as lord of Cardigan, agreeably to the charter granted by the king of England, which confirmed to Llewelyn the title of Prince of Wales. King Edward I. in 1277, obtained great advantages over Llewelyn, and dictated hard conditions of peace, to enforce which he built and garrisoned a castle at Aberystwith. Edward now divided Wales into counties, and annexed it to England in 1284; and the better to settle his affairs, soon afterwards made a progress through Cardiganshire, the history of which must from this time be considered in connexion with that of England. We will only mention that, in 1404, Owen Glendower took Aberystwith castle, which was recovered by Prince Henry in 1407. The earl of Richmond (afterwards Henry VII.) passed through Cardiganshire in his way from Milford to Bosworth field in 1485. A curious privilege was granted by Charles I. to Mr. Bushel, then proprietor of many mines in Cardiganshire—the permission to coin the metal that he raised. A mint was established by him in Aberystwith castle, and afterwards removed to Shrewsbury. The money coined by him, of which some has within a few years been dug up at Aberystwith, was distinguished by a plume of feathers on the reverse.

Cardiganshire abounds with antiquities. There are, besides many Druidical remains, a Roman station at Llanio, and a Roman road traversing the county in a N. and S.

direction from that place. Remains of castles are either standing, or it is evident that such fortifications have existed at Cardigan, Aberystwith, Lampeter, Ystradmeirch, Glyn-nin, Llanysted, Dyarth, Moyddyn, Aberinon, Penwedic, Castell Gwallter, Castell Cadwyn, Hen Castell, Castell Flenis, &c. There were also religious houses at Cardigan, Lampeter, Llanysted, Llandewi Brevi, and Strata Florida. The abbey last mentioned, of which a fine Saxon arch and some walls now stand, is situated about five miles from Tregaron. It was the depository of part of the records of the principality, and the burial-place of many Welsh princes and celebrated bards. Rhys Gruffydd founded the first abbey in 1164; this building however was destroyed, and a new one erected two miles distant from the original site. We also find that Edward I. granted 7s. to the abbey of Strata Florida for damages sustained during the late war and conflagration.

In 1822 a college for the education of the Welsh clergy was founded at Lampeter: this institution, which at a cheap

rate affords for better instruction than the old collegiate schools, is of great public utility. The students reside within the college, which is well conducted by a principal, a vice-principal, and professors of Greek, Hebrew, Welsh, divinity, &c. The bishop of the diocese, who is visitor, ordains no one who has not graduated at Oxford, Cambridge, or Lampeter.

Statistics.—Population. Cardiganshire has no manufacture of any importance. According to the census of 1831 it appears that of 14,598 males twenty years old and upwards residing in this county 8686 were engaged in agriculture, and 248 in manufactures or in making manufacturing machinery. Of the latter number about 240 were employed in weaving flannel and other light woollen goods, the yarn for the purpose being spun by cottagers residing in the county.

The following summary of the population for May, 1831, shows the number of inhabitants and their occupations in each hundred of the county.

HUNDREDS, &c.	HOUSES.				OCCUPATIONS.			PERSONS.			Males twenty years of age.
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	All other families not included in the two preceding classes.	Males.	Females.	Total of persons.

Troedysaur . . .	2,471	2,515	18	42	1562	527	426	5,746	6,306	12,054	2,687
Cardigan (borough) .	560	688	10	6	20	213	455	1,749	1,646	2,795	546
Totals . . .	13,045	13,652	115	324	7246	3243	3163	30,868	33,912	64,780	14,598

The population of Cardiganshire at each time of the census being taken in this century was:—

	Males.	Females.	Total.	Inc. per Cent.
1801	42,956	..
1811	50,260	17
1821 . . .	27,898	29,886	57,784	14.97
1831 . . .	30,868	33,912	64,780	12.10

Showing an increase between the first and last periods of 21,824 persons, or little more than 50½ per cent., which is below the general rate of increase throughout England.

County Expenses, Crime, &c.—The sums expended for the relief of the poor at the three periods of

1811 were £ 12,386	equal to	4s. 11d.	for each inhabit-
1821 .. 14,886	..	5s. 1d.	ant.
1831 .. 17,591	..	5s. 5d.	

The expenses for the same purpose in the year ending 25th March, 1834, was 18,624l. 18s.; and assuming that the population has increased for the last three years in the same uniform ratio as during the ten preceding years, the above sum averages 5s. 2½d. for each inhabitant. All these averages are below those for the whole of England and Wales.

The sum raised in this county for poor's rate, county rate, and other local purposes, in the year ending 25th March, 1833, was 23,242l. 11s., of which was expended—

	£.	s.
For the relief of the poor . . .	18,821	7
For suits of law, removal of paupers, &c. . .	745	19
For other purposes . . .	3,637	5
	£ 23,204	11

The descriptions of property assessed for local purposes are not distinguished in the returns made up for the year ending March, 1834. The total amount levied in that year was 23,683l. 17s., and the expenditure was as follows:—

	£.	s.
For the relief of the poor . . .	18,624	18
In suits of law, removal of paupers, &c. . .	637	7
For other purposes . . .	3,136	5
Total . . .	£ 22,448	10

There has therefore been a saving in the expenditure for

the relief of the poor in 1834, as compared with the preceding year, of not 1 per cent. The other expenses were however less in 1834, and consequently the whole amount of saving is raised to about 3½ per cent.

The number of turnpike trusts in Cardiganshire, as ascertained in 1829, was 2; the number of miles of roads under the charge of the trustees was 250; the annual income arising from the tolls and parish composition was 1752l.; the annual expenditure 1662l.

The county expenditure for various purposes, exclusive of the relief of the poor, was as follows in 1833:—

	£.	s.	d.
Bridges and roads leading to them . . .	378	12	0
Gaols . . .	0	8	0
Expenses of criminal trials at			
quarter-sessions . . .	102	7	0
circuits . . .	39	18	2
bridge-master and			
county surveyor . . .	31	10	0
sheriff and under			
sheriff . . .	4	6	6
coroners . . .	47	9	6
militia . . .	21	0	0
county elections . . .	29	13	10
shire halls . . .	10	13	4

The sum levied for county rate in 1833 was 1500l.

The number of persons charged with criminal offences in Cardiganshire, in the three septennial periods ending with 1820, 1827, and 1834, were 72, 58, and 63 respectively, making an average of 10 annually in the first, of 8 in the second, and of 9 in the last period.

The number of persons tried at quarter-sessions in 1831, 1832, and 1833, were 9, 4, and 2, respectively: of these there were committed for—

	1831.	1832.	1833.
Felonies . . .	8	1	2
Misdemeanors . . .	1	3	0
	9		2
The number convicted was . . .	4	0	2
acquitted . . .	4	2	0
Discharged by proclamation . . .	1	2	0

At the assizes and sessions in 1835, there were only 16 persons in this county charged with crimes; out of this number 1 was tried for housebreaking, 11 were tried for simple larceny, 1 for sheep-stealing, 1 for larceny from the person, and 1 for riot. Of these offenders 8 were convicted; of whom were sentenced—1 to transportation for 7 years, and 6 to imprisonment for various periods between 2 years and under 6 months; the remaining 1 was discharged on sureties. Two out of the 15 offenders were females convicted of simple larceny, 1 of these was between 16 and 21 years of age, the other above 60 years. The ages of the males were 2 aged 12 years or under, 1 aged 16 years and above 15, 3 aged between 21 and 16, 2 between 21 and 30, 3 between 30 and 40, 1 between 40 and 50, and 1 between 50 and 60. In the whole number 9 could read and write, 1 could read only, and 3 could neither read nor write, the degree of instruction of the remaining 2 was not ascertained. The proportion of the offenders to the population was 1 in 4318. The centesimal proportions in which the various crimes were committed were as follows:

Offences against property committed with violence	6.67
Offences against property committed without violence	86.66
Riot	6.67
	100

Cardiganshire has one savings-bank; the number of depositors and amount of deposits in the three years ending 1834 were respectively as follow:

	1832	1833.	1834.
Number of depositors	671	683	321
Amount of deposits	£15,506	15,973	9589

The various sums placed in the savings-bank in 1834, and the number of depositors, are thus distinguished into classes:—

£.	Depositors.	Deposits.
Not exceeding 20	153	2183
" 50	123	3691
" 100	34	2766
" 150	9	1038
" 200	2	311
	321	£ 9589

Education—The following statements are taken from an abstract of the inquiry on education made by order of parliament in the session of 1835:—

	Schools	Scholars	Total
Infant Schools	3		
Number of infants at such schools, aged from 4 to 7 years:—			
Males		40	
Females		30	
			70
Daily Schools	92		
Number of children at such Schools, aged from 4 to 14 years:—			
Males		1239	
Females		669	
Sex not specified		2174	
			4082
Total number of Schools	95		
Total of children under daily instruction		4152	
Sunday Schools	175		
Number of children and others at such Schools, aged from 4 to 90 years:—			
Males		3,425	
Females		3,284	
Sex not specified		11,940	
			-18,649

Schools established by Dissenters, included in the above statement:—

	Schools.	Scholars.
Daily Schools	5	267
Sunday Schools	109	14,621

Schools established since the year

1818:		
Infant and other daily schools	26	2,041
Sunday Schools	149	16,985

There appear from the return to be 3 boarding schools in Cardiganshire, which are included in the daily schools. Most of the Sunday schools are attended by adults and aged persons, as well as children: it is said many continue in them to their death. Thirty-two of the Sunday schools are returned from places where no other schools exist; and the persons who attend them, 2897 in number, cannot be supposed to receive instruction in any other school; but with this exception, it is probable that many of the scholars in the daily schools likewise attend the Sunday schools.

Calculating the average annual rate of increase in the population of the county as being the same from 1831 to 1834 as in the preceding ten years, the approximate number of inhabitants between the ages of 2 and 15 at present living in Cardiganshire is 24,521. The number of persons receiving education is 22,801; and for the reasons just stated (many of these being adults and many twice enumerated), we find that there must be a considerable proportion of the young population not receiving education in this county. There is a lending library of books attached to one of the schools.

CARDINAL, the highest dignity in the Roman church and court next to the pope. The cardinals are the electors of the pope, and his councillors.

In the early times of the church this title was given to the incumbents of the parishes of the city of Rome, and also of other great cities. The term is derived from the Latin adjective 'cardinalis,' which means 'principal,' or from the substantive 'cardo,' which means a 'hinge,' the cardinals being the hinges or supports of the church, and the pillars of the Roman clergy. There were also cardinal deacons, who had the charge of the hospitals for the poor, and who ranked above the other deacons. The cardinal priests of Rome attended the pope on solemn occasions. Leo IV., in the council of Rome, 853, styled them 'presbyteros sui cardinis.' Afterwards the title of cardinal was given also to the seven bishops suburbicarij, or suffragan of the pope, who took their title from places in the neighbourhood of Rome, namely, Ostia, Porto, Santa Rufina, Sabina, Palestrina, Albano, and Frascati. These bishops were called hebdomadarij, because they attended the pope for a week each in his turn. The cardinals took part with the rest of the Roman clergy in the election of the pope, who was often chosen from among their number. About the beginning of the twelfth century, the popes having organized a regular court, bestowed the rank of cardinal priest or deacon on any individual of the clergy or even lay that they thought proper, whether Roman or foreign, giving to each the title of some particular church of Rome, without any obligatory service being attached to it. The churches which give titles are, however, even yet, under the complete jurisdiction of their respective titulars. Thus they made the cardinals a separate body elected for life; and the officiating priests of the Roman parishes were by degrees deprived of the title of cardinals. Nicholas II., in 1159, issued a decree, limiting the right of election exclusively to the cardinals thus appointed by the pope, leaving however to the rest of the clergy and the people of Rome the right of approving of the election of the new pope, and to the emperor that of confirming it. In course of time however both these last prerogatives became disused. Alexander III., in 1179, issued a decree, requiring the unanimous vote of two-thirds of the cardinals to make an election valid. For a long time the bishops in the great councils of the church continued to take precedence of the cardinals. In France, Louis XIII., in the sitting of the parliament of Paris of the 2nd October, 1614, first adjudged to the cardinals the precedence over the ecclesiastical peers or bishops, and abbots. This precedence however has been often contested. Pius V., in 1567, forbade any clergyman to assume the title of cardinal except those appointed by the pope. Sixtus V., in 1587, fixed the number of cardinals at seventy, namely, the six bishops suburbicarij above-mentioned (the title of Santa Rufina being joined to that of Porto, and that

of Velletri to Ostia), fifty cardinal priests, and fourteen deacons. Most of the cardinals, both priests and deacons, bear the title of a church of the city of Rome. Several of the cardinal priests are bishops of some particular diocese at the same time; still they bear the title of the particular church of Rome under which they were made cardinals. The body of the cardinals is styled the Sacred College. The number of seventy is seldom complete, the pope generally leaving some vacancies for extraordinary cases. Most of the cardinals who reside at Rome either enjoy ecclesiastical benefices, or are employed in the administration either spiritual or temporal; others belong to wealthy families, and provide for their own support; and those who have not the same means receive an allowance from the government of about 800*l.* per ann., on which a deduction is made of 10 per cent. Several of the cardinals belong to monastic orders, some of whom, even after their promotion, continue to reside in their respective convents. The establishment of a cardinal is generally respectable, but moderate: a carriage and livery-servants are however an obligatory part of it. They generally dress in a suit of black, after the garb of clergymen, but with red stockings, and a hat bordered with red. On public occasions their costume is splendid, consisting of a red tunic and mantle, a 'rochet' or surplice of fine lace, and a red cap, or a red three-cornered hat, when going out. Members of religious orders, if created cardinals, continue to wear the colour of their monastic habit, and never use silk. The present pope, being a Camaldolese monk, was always, when a cardinal, dressed in white. This costume began to be adopted in the thirteenth century. When the pope promotes a foreign prelate to the rank of cardinal, he sends him a messenger bearing the cap: the hat can only be received from the pope's own hands; the only exception is in favour of members of royal houses to whom the hat is sent. Urban VIII., in 1630, gave to the cardinals the title of Eminence, which was shared with them by the grand master of the order of Malta, and the ecclesiastical electors of the German or Roman empire only. The pope often employs cardinals as his ambassadors to foreign courts, and the individual thus employed is styled Legate *a Latere*. A cardinal legate is the governor of a province, known by the name of a Legation, whereof, till the late revolution, 1830, there were four. The chief secretary of state, the camerlengo or minister of finances, the vicar of Rome, and other leading official persons, are chosen from among the cardinals.

The Council of Cardinals, when assembled under the presidency of the pope to discuss matters of church or state, is called 'Consistorium.' There are public consistories, held on some great occasions, which correspond to the levees of other sovereigns, and private or secret consistories, which are the privy council of the pope. With regard to the forms of the election of a pope, see CONCLAVE.

In Moreri's Dictionary, art. 'Cardinal,' is a list of all the cardinals elected from 1119 till 1721, their names, countries, titles, and other dignities, the date of their election, and that of their death, which may be found useful for historical reference.

CARDINAL POINTS. [COMPASS.]

CARDING. [WOOL.]

CARDITA. [SUBMYTILACEA.]

CARDITIS, inflammation of the heart. When this term is used in its strict sense, it denotes inflammation of the muscular substance of the heart. True inflammation affecting the muscular substance of the heart, and restricted to its fleshy fibres, is a rare disease. But little is known of the symptoms of this malady during life; and perhaps the only unequivocal evidence of its existence afforded by examination of the organ after death, is the presence of pus infiltrated among the muscular fibres. [HEART, DISEASES OF.]

Carditis, or inflammation of the heart, is a disease oftener observed in the horse than in any other domesticated animal. Its symptoms are very characteristic. The pulse is quickened to a considerable degree; but it is also peculiarly bounding and violent. The beatings of the heart may be seen to shake the whole of the frame, and may be heard at a distance of several feet, while the countenance expresses unusual excitement, and there is an unwonted energy attending every motion.

The remedy is simple, and generally effectual. The horse should be bled, until the action of the heart is materially subdued, and the bleeding should be repeated if the bounding pulse threatens to return. A strong dose of physic should be given, and digitalis administered in large and frequent doses.

If the disease is suffered to proceed, the inflammation will speedily extend to the pericardium; and the consequence of inflammation of this membrane will be, the effusion of serous fluid into the bag of the heart, impeding, and at length arresting its pulsation. The approach of this termination of carditis will be indicated by the weakened intermittent pulse roused to a fluttering action by the least disturbance, and by the obscure struggling of the heart as heard when the ear is applied to the left side.

CARDOON, a kind of artichoke, the *Cynara cardunculus* of botanists, a Spanish plant, the thick, fleshy stalks and ribs of whose leaves are blanched and eaten as an excellent vegetable. They are usually stewed or dressed with marrow, and have been reckoned to possess aphrodisiacal properties. In this country they are not much esteemed, but they form an important object in the Paris market. They are cultivated somewhat in the manner of celery. The seeds are sown in a hot-bed, and when the plants that they produce have become well established after two or three successive pottings, they are finally planted from three to four feet apart. When they are half-grown, in August, either the stems are earthed up, or they are blanched by having bay-bands turned round them. They are fit for the kitchen by the middle of November. The finest variety is that called the Cardon de Tours.

CARDUELIS. [FRINGILLIDÆ.]

CARIAMA or **SARIAMA** (zoology): the name by which the *Palamedea cristata* of Gmelin, *Dicholophus cristatus* of Hager, *Microdactylus* of Geoffroy, the *Saria* of the Guarani of Paraguay, and the *Seriemia* or *Cerema* of the Brazilian natives, is known to the Portuguese colonists of Brazil.

Marcgrave, Piso, D'Azara, Geoffroy, and the Prince de Wied, have entered into a detailed history of this bird, which has always attracted the notice of zoologists on account of the curious relations which its structure indicates to the *Grallatores* (waders), the gallinaceous birds, and even the *Struthionidæ*.

Locality.—The great solitary mountain-plains, surrounded by the forests which extend over so large a proportion of Brazil, and where its sonorous voice often breaks the silence of the desert. It is also found in Paraguay, but is said to occur there more rarely.

Food.—In a state of nature lizards, insects, and molluscos animals, and not improbably small seeds occasionally.

Habits.—The habits of the wild Cariama are of the most retired description. A tenant of the vast solitudes that form its wide spreading home, it flies from the face of man; and being almost always on the watch, is very difficult of approach. Stalking slowly on the plain its eye instantly notes the distant intruder, and, after a moment's hesitation, it decides either to stay or fly, according to the circumstances. Those who have had the best opportunities of observing them in their native wilds state that the hunters, though surrounded by these birds, cannot, without considerable labour, obtain them. As soon as the bird perceives that it is pursued, it sets off with great rapidity; the pursuer follows on horseback, but it is not till after a sharp and tedious course, with all its turns and windings, that the Cariama, wearied out, either crouches on the ground, or alights on some bush or tree. Till this happens the horseman in vain seeks for an opportunity to throw his lasso or pull his trigger.

But wild as the bird is in its natural state, it is easily domesticated, and will live sociably with the other tenants of the poultry-yard. In this state they will eat little pieces of meat, but are said to refuse maize, though it is probable that other kinds of grain may not be disagreeable to them. When thus tamed they will walk about the hamlet or village where they have been brought up, and even return after taking short trips in the fields like the poultry. The flesh is described as very good food; the Brazilians however do not hunt it for the game-bag.

Nest, &c. composed of dry sticks and branches, covered with cow-dung, and placed upon a low or a moderately high tree. The eggs are generally two in number and white.

Description.—Neck covered with long, loose, barbed feathers, floating and silky upon the nape somewhat like those of the bittern: when the bird is excited or frightened it can raise them. A light crest consisting of a few disunited feathers forms an ornamental tuft on the front, and advances upon the base of the bill which it overhangs, reminding the observer of the crests of the *Rupicolæ* (cocks of the rock) in its disposition. Space round the eyes naked, the nakedness, which is bluish, reaching to the bill. The

upper eye-lid fringed with long dark eye-lashes, and slender, and the toes very short, whence name. *Tail* rounded, and of moderate length.

The general colour of the *Gariama* is an earthy-brown on the upper parts, while the lower parts are whitish. All the neck feathers are finely rayed with zig-zags of darker brown than that which forms the general ground colour of the plumage. The two middle feathers of the tail are brown: the others for the most part black, with white extremities, and marbled with black upon a white ground at their insertion. The wing-feathers are blackish and traversed by white bands dotted with blackish. There are delicate zig-zags of a clear brown on the feathers of the front of the neck, the ground colour of these feathers being whitish. The feathers of the breast and belly are longitudinally rayed with white in the direction of the shafts. The naked part of the leg, the feet, and the toes are of an orange-red. The bill, which is of a bright coral red in the adult, is blackish or marbled with black and reddish in the younger birds. The iris is yellow.

D'Azara gives thirty inches as the length of the young bird described by him; that of the Prince de Wied was half an inch more, and the adult male of the museum of the Pays Bas, from which Temminck's figure was taken, measures, according to him, thirty-two inches.

Nestlings.—Covered with down, and with the iris of a very lively yellow. They are very soon able to run.

[*Dicholophus cristatus*.]

Temminck, after observing that the *Gariama* at first view seems to offer some resemblance to the secretary bird of Africa (*Gypogeranus serpentarius*), remarks that this resemblance vanishes upon a closer inspection, and that, if it be permitted to form any judgment from the forms solely, it would seem probable that the skeleton of the *Gariama*, which was not known when he wrote, ought to have some relationship with that of the common bittorn (*Botaurus stellatus*), of the Agouti (*Psophia crepitans*), and the *Grallatores* generally. There is now a skeleton of a female in the museum of the Zoological Society of London, presented by the earl of Derby, in whose possession the bird died, and as the form is a very peculiar and interesting one, we subjoin Mr. Martin's description of it in 'The Proceedings' of the Society:—

In its general aspect, the skeleton of the *Gariama* is very remarkable. The comparative shortness of the neck, the compactness of the chest and stoutness of the ribs, together with the abbreviated condition of the wings, appear as if

long out of harmony with the length of the limbs, especially of the *tibia* and *tarsus*, while the toes concluding this length of limb are short, the hinder one being situated high and not touching the ground.

The skull, as in the cranes, is arched above, but rises on the vertex to a more abrupt elevation, the arch in the Stanley crane being a regular sweep from the base of the upper mandible to the occiput. The orbits are large and separated by a bony septum, with a central and posterior perforation, and a slight superior fissure. In the Stanley crane the central perforation is large and continuous with the posterior; the superior fissure being also more decided. The supra-orbital process of the lacrymal bone is large, prominent, and directed backwards, as it is in the Stanley crane. There is also a large posterior orbital process, forming part of the rim of the orbit; and before the *os quadratum* there projects forwards and downwards a process of the temporal bone, analogous, I suspect, to the zygomatic process, for the long bone stretching to the upper mandible from the *os quadratum*, which in the present bird is remarkably slender, cannot be called a true zygoma. Between these two processes is the depression for the temporal muscle. The nostrils are large, wide, ovoid, and open.

In the lower jaw there is nothing remarkable. It may be observed however that a slit or a long foramen marks the union of the basal to the anterior portion of the bone, instead of a simple suture. The coronoid process is very small.

The vertebrae are short and stout, and more resemble those of a gallinaceous bird than of a crane; in fact, they differ little from those of the crested curassow. Their number is as follows:—

Cervical	13
Dorsal	7
Sacral	12 apparently
Caudal	8

But that a rib arises on each side from it, the last or seventh dorsal vertebra is so completely consolidated to the sacrum that it cannot be distinguished from that portion of the column; this is also the case in the black crested curassow, with the last dorsal vertebra, and in the Stanley crane with the two last.

The sternum differs considerably in figure from that of the Stanley crane. For independently of the absence of a channel in the anterior edge of the keel for the reception of the trachea, the keel is neither so deep, nor is its anterior apex even in contact with the point of the *os furcatum* (there being a firm consolidation in the Stanley crane), while its posterior edge is narrow and prolonged as in gallinaceous birds, whereas in the Stanley crane it is broad and squared. The total length of the sternum is 4½ inches. The greatest depth of the keel 1½. The keel does not arise abruptly from the body of the sternum, but the latter merges gradually into it.

The *os furcatum* is very slender and depressed towards the coracoid bones, its figure is triangular, and the apex does not reach the keel of the sternum by nearly half an inch. The *Gariama* is a bird of feeble powers of flight, very different from the crane in this respect, and exhibiting an according modification of the osseous parts connected with aerial progression.

The ribs, seven in number on each side, are short and strong; the first two are false: in the Stanley crane I can only find one false rib on each side; while all the rest are long, somewhat slender, and extend nearly two inches beyond the posterior margin of the sternum; whereas in the *Gariama* the posterior sternal apex extends beyond the ribs, which here make a very obtuse angle at their junction with the cartilages, or rather bones of sternal attachment.

The clavicles offer nothing remarkable.

The bones of the wings are short, the fore arm and humerus being of equal length—4½ inches; the hand consists of the usual bones in birds, and is about 3½ inches in length.

The femur, as in the crane, is short and strong, measuring 3½ inches. The tibia is slender, measuring 6½ inches in length, the projecting crista before its upper articulating surface is very bold; as in the crane, there is a large internal plate and an external pointed process, with a deep hollow between them, occupying the front of the upper end of the tibia. The fibula is, as usual, a slender stylet, and 3 inches long. The tarsus is 6½ inches long, of a squared form towards its upper extremity, with an anterior and posterior groove very strongly marked, and a slighter groove

on each side. The accessory the base of the hind toe, an inch from the lower extremity of the tarsus. The toes are short and stout, but consist of the usual number of phalanges.

Though the Gariama, in its osseous structure, exhibits but little resemblance to the birds of the Raptorial order, it approaches that order very remarkably in the structure of the eye, which is surrounded by a firm consolidated osseous ring. This ring departs materially in its formation from what obtains among the *Grallatores* generally, where it is imbricated, and slight, and indeed scarcely merits the name of osseous.

Our limits will not permit us to enter at large into the anatomy of the bird, for which we refer the reader to Mr. Martin's paper, but we may observe that, according to Mr. Martin, in the whole of the visceral arrangement a close affinity may be observed to the *Grus* tribe. In the Stanley crane (*Anthropoides paradiseus*, Bechst.) the intestines are similarly disposed in folds or loops, and the two *cæca*, given off 6 inches from the anus, are 4 inches long. In the Stanley crane however the muscular coat of the gizzard is thicker than in the Gariama, being in some parts an inch across, while in the latter bird it is about $\frac{1}{2}$ of an inch; hence is there in this point an index of a less vegetable regimen. In the Stanley crane, the total length of the intestines is 5 feet 3 inches. In the Gariama, it is 3 feet $5\frac{1}{2}$ inches.

CARIBS, or CARIBBEES, is the name given by the first European navigators to one of the aboriginal tribes of South America, and which has been adopted by all European nations, though they call themselves Carina, Calina, and Callinago.

At the time of the arrival of the Europeans in America the Caribs were in possession of the smaller islands of the West Indies which lie between Puerto Rico and the Gulf of Paria. The Caribs made stout resistance against the European intruders; but at last they were compelled to yield and to abandon the islands after the greater part of them had fallen in continually repeated conflicts. A small number still exist on the Islands of Trinidad, St. Vincent, and Dominica. On St. Vincent they were formerly more numerous, but on their rebellion in 1796 they were transplanted by the English to the Island of Roatan, in the Bay of Honduras, whence, in 1797, they were removed by the Spaniards to the neighbourhood of Truxillo in Guatemala, where they still live; but a considerable number of them have lately been destroyed by the government, on account of their turbulent and rebellious character.

Though the Caribs have been nearly extirpated from the islands, there still exists a considerable number on the continent of South America. They are principally found on the banks of the Lower Orinoco and of the Caroni, one of its principal tributaries; but they extend also farther S., and a few of them are met with in the settlement of Demerara and in French Guiana. Those who live within the republic of Venezuela are partly settled in the missions along the Caroni and Orinoco, but a considerable number are still independent under their own caciques, to whom they pay great respect.

The Caribs are distinguished from the other native tribes of America by their athletic stature and their great courage and firmness of purpose. They speak of other savages with contempt and disdain, and think themselves a privileged race. They are also evidently gifted with mental powers superior to those of the other tribes. The Caribs have been accused of cannibalism.

Humboldt is of opinion that the Galibes in Cayenne and the Tuapocas and Cunaguaras, on the coast of Cumana, and the Jaci in Trinidad and the province of Cumana, and perhaps also the Guarivas, are tribes of the great Caribbean nation. Their language differs from those of their neighbours: there is indeed a frequent analogy between the words and the grammatical structure in the languages of these tribes; but still their language must, to some extent, be considered as different, since they are unable to understand. (Humboldt; Haefkens, &c.)

ISLANDS, THE, have received their name

By this denomination are understood the whole series of islands, which on the N. begin with the Virgin Islands, and on the S. terminate with Trinidad.

[AMILLAS.]

CARICA, a remarkable tree found in various parts of

South America, with a simple unbranched erect trunk, from twelve to twenty feet high, abounding in a milky juice, having broad, ensiform leaves, a foot at least long, and unisexual flowers, the males of which are monopetalous, with ten short stamens inserted in the mouth of the corolla; the females polypetalous, with a single ovary having a starry sort of stigma. The fruit is thus described in the 'Botanical Magazine': 'The corolla falls away, and the germen in coming to maturity becomes pendent; the tree, too, advancing in height casts its lower leaves from below the flowers, and the fruit constituting a large oblong kind of berry, or more correctly speaking pepo, rests suspended upon the leafless part of the trunk, much in the same way as that of the Artocarpus or bread-fruit. The surface, when the fruit is ripe, is a pale and rather dingy orange-yellow, obscurely furrowed, and often rough with little elevated points. The flesh is very thick, coloured, but paler than the outside, and there passes through it longitudinally five bundles of vessels. In the centre is a considerable cavity, with five longitudinal ridges, and these are thickly clothed with numerous seeds.'

This fruit is called the *papaw*, and is accounted of considerable interest in the tropical part of the world. An excellent history of its uses is compiled in the work already quoted, from which we borrow the following: 'The papaw tree is of rapid growth. St. Pierre probably spoke from his own knowledge, when he described Virginia as having planted a seed, which in three years time produced a trunk twenty feet high, with its upper part loaded with ripe fruit. It is for the sake of this fruit, mainly, that the plant is cultivated; but if the flavour were not better than that yielded by what ripened in our stove, I cannot recommend it as at all agreeable. Browne, in his "Natural History of Jamaica," tells us, that "it has a pleasant sweetish taste, and is much liked by many people; that while young it is commonly used for sauce; and when boiled and mixed with lime juice and sugar is not unlike, or much inferior, to that made of real apples, for which it is commonly substituted." In the opinion of Sloane it is not a very pleasant fruit, even when helped with pepper and sugar; and the more ordinary use, he adds, of this fruit is before it is ripe, when, as large as one's fist, it is cut into slices, soaked in water till the milky juice is out, and then boiled and eaten as turnips, or baked as apples. The juice of the pulp, according to Descourtilz, in the "Flora Médicale des Antilles," is used as a cosmetic, to remove freckles on the skin caused by the sun; and the negroes in the French colonies employ the leaves to wash their linen instead of soap. As a medicinal plant the papaw tree is particularly deserving of notice. Hernandez long ago spoke of the milky juice of the unripe fruit as a powerful vermifuge; which has been confirmed by M. Charpentier Cossigni, as mentioned in the "Asiatic Researches" by Dr. Fleming (vol. ii., p. 182). A single dose, that gentleman says, is sufficient to cure the disease, however abundant the worms may be. Another French writer (Poupoé Desportes) recommends the use of the seed instead of the juice. But the most extraordinary property of the papaw tree is that which is related, first I believe by Browne, in his "Natural History of Jamaica," namely, that "water impregnated with the milky juice of this tree is thought to make all sorts of meat washed in it very tender; but eight or ten minutes' steeping, it is said, will make it so soft that it will drop in pieces from the spit before it is well roasted, or turn soon to rags in the boiling." Mr. Neill mentioned this circumstance more fully in his interesting "Horticultural Tour through Holland and the Netherlands;" and it has repeatedly been confirmed to me by gentlemen of this country who have been long resident in the West Indies, and who speak of the employment of the juice for such a purpose as of quite general occurrence; and more, that old hogs and old poultry which are fed upon the leaves and fruit, however tough the meat they afford might otherwise be, are thus rendered perfectly tender, and good too, if eaten as soon as killed, but that the flesh very soon passes into a state of putridity. The juice causes a separation of the muscular fibres. Nay, the very vapour of the tree serves the purpose; hence many people suspend the joints of meat, fowls, &c., in the upper part of the tree, in order to prepare them for the table. Such is the effect upon hogs that feed upon the fruit, that the good housewives reject the flesh of such if it is destined for salting, well knowing that it is not sufficiently firm for that purpose.

Whether this power of hastening the decay of meat be attributable to the animal matter or fibre contained in the

juice of the Papaw or not, I will not pretend to say; but the presence of such is a fact scarcely less wonderful than the property just alluded to. Two specimens of the juice were brought from the Isle of France; in the one it had been evaporated to dryness, and was in the state of an extract; in the other, the juice was preserved by being mixed with an equal bulk of rum. Both were subjected to analysis by Vanquelin. The first was of a yellowish-white colour, and semi-transparent. Its taste was sweetish. It had no smell, and was pretty solid; but attracted moisture when kept in a damp place. The second was reddish-brown, and had the smell and taste of boiled beef. When the first specimen was macerated in cold water, the greatest part of it dissolved; the solution frothed with soap. The addition of nitric acid coagulated it, and rendered it white; and when boiled, it threw down abundance of white flakes. When the juice of the Papaw is treated with water, the greatest part dissolves; but there remains a substance insoluble, which has a greasy appearance. It softens in the air, and becomes viscid, brown, and semi-transparent. When thrown on burning coals it melted, let drops of grease exude, emitted the noise of meat roasting, and produced a smoke which had the odour of fat volatilized. It left behind it no residue. The substance was fibrine. The resemblance between the juice of the Papaw and animal meat is so close, that one would be tempted to suspect some imposition, were not the evidence that it is really the juice of a tree quite unquestionable. This fibrine had been supposed, previously, to belong exclusively to the animal kingdom; but it has since been found in other vegetables, especially in Fungi.

CARIESFORT, a decayed borough in the barony of Ballinacor and county of Wicklow in Ireland; it formerly returned two members to the Irish parliament, for which John Earl of Cariesfort received 15,000*l.* compensation at the Union. The only object of interest connected with Cariesfort is the charter-school established 4th Charles I. by 53 Geo. III. c. 107, vested in the commissioners of education in Ireland, and subsequently regulated along with the other royal charter-schools of Ireland by acts of Geo. IV. and Will. IV. There are now about 361 acres of land belonging to the school, which educates 110 scholars, and on which 500*l.* have been lately expended. The town is a miserable village, and is now known by its ancient name of Moyereedin. (*Reports of Commissioners.*)

CARILLON. [CHIMES.]

CARINA, in botany, the two oblique front petals of a papilionaceous flower, united by their contiguous edges into an organ having a figure something like that of the keel of a boat.

CARINARIA (zoology), the name of a genus of molluscous animals arranged by Cuvier under his fifth order of Gastropods (Lamarck's Heteropoda) as the type of that order, and by De Blainville under the first family (Neritopoda) of his order Nucleobranchiata. The shells of this genus were formerly known to collectors under the name of 'Venus's Slipper' and 'Glass Nautilus'; indeed one of the species is the *Argentata vitreus* of Gmelin.

M. Verany's description published in the 'Zoological Journal,' vol. V. p. 325, in French, is tolerably accurate, with the exception of his having mistaken the back for the belly of the animal, and *vice versa*. The error arose, no doubt, from the habit of the animal, which swims upon its back, and thus M. Verany, without adverting to the situation of the brain and the relative position of the other parts, appears to have been led to describe the side that floated uppermost as the back, whereas that part, which is analogous to the belly in the Gastropods, occupies that position not only when the animal is in motion, but most probably when it is at rest.

The body is subcylindrical, elongated, transparent, dotted with elevated points, prolonged posteriorly, and furnished towards the upper part of its posterior extremity with a sort of fin which performs the part of a rudder. A reddish, thin, compressed, subcircular fin, beautifully reticulated by decussating muscular fibres, furnished with a sort of acetabulum or sucker, rises from the belly nearly opposite to the point on the back occupied by the shell. With the aid of this fin it floats along. M. Verany says that notwithstanding the greatest possible attention he has not been able to discover the use of the sucker, or rather suctorial disk, in the ventral fin; but there can be little doubt that it is analogous to the foot in gastropods, and that the animal avails itself of its powers of adhesion by sticking to rocks or other

submarine bodies, and thus lying at anchor, as it were, in repose, with the frail shell that protects the circulating and respiratory organs together with the liver and generative gland lowermost, the same position occupied by it when the animal is in motion.

The head is capable of contraction within the body, and is provided with a sort of retractile proboscis. There are two tentacula of some length and of a subconical shape placed laterally at the insertion of the head; and there are two eyes situated at the base of the tentacula. The mouth is furnished with a circular jaw, armed with four rows of teeth, of which the two internal ones are fixed and small.

Organs of respiration, &c.—These, together with the heart and vent, are protected by a delicate transparent shell, somewhat compressed, without a spine, but with a summit a little recurved backwards, and the opening wide, entire and oval. The vent is under the edge of the mantle which envelops the organs above mentioned, and lines the shell.

The scales, according to M. Verany, are separated as in the *Firola* (*Pterotrachea*); the sexual organ of the male being placed a little anteriorly on the right side under the subventral belly fin, that of the female is near the vent.

Digestive organs.—These consist of a retractile tube furnished within with a horny rasp, and a short oesophagus, opening into a slightly dilated stomach which is continued into an intestinal tube passing straight towards the shell into which it enters and, making a convolution, terminates in the vent.

Nervous System.—There is between the eyes a ganglion from which many nerves are given off, and of these six are directed forwards and four backwards. Of the six directed forwards two go towards the mouth, and appear to provide for the action of the probosces, two belong to the tentacula, and two to the eyes. Of the four directed backwards two go directly to the nucleus in the shell, and the other two unite under the fin from whence they ramify into five branches, three of which are appropriated to the belly-fin, and two go towards the tail.

Example. Carinaria Mediterranea.—M. Verany states that it is to be found all the year on the coasts (in the neighbourhood of Nice), but that it is sufficiently abundant in the months of May, June, and July. He further observes that it is rare to find it with the shell entire, that it feeds on gelatinous bodies and on very small fishes, such as *Atherina nona* (the dwarf Atherine), and that he has often found in the stomach the remains of other *carinariae*, which satisfies him that the species is mutually destructive.

Delle Chaze, who has placed the animal in its proper position with relation to the brain, has given a careful and detailed account of its organization in his 'Memorie sulla Storia e Natura degli Animali senza Vertebre del Regno di Napoli,' vol. d. p. 214, illustrated in his plates 14 and 15. Delle Chaze makes the spermathecal canals rise at the posterior base or insert of the ventral fin and proceed to the genital organ, near the origin of what we have termed the rudder fin; but he gives no external view of the apparatus so conspicuous in M. Verany's figure.

[*Carinaria Mediterranea*, wale.]

a, situation of the ganglion or brain; b, eye; c, head; d, retractile tube; e, tentaculum; f, digestive tube; g, shell containing the organs of respiration, heart, &c.; h, the posterior or rudder fin; i, ventral fin; k, the sucker; l, l, nerves. The figure, with slight modification, is taken from Verany's.

We had an opportunity of comparing together a specimen of *Carinaria* from the Mediterranean and one captured by Mr. George Bennett in the Indian Ocean, 33° S. lat., and 22° W. long., but the comparison did not present any perceptible difference between the specimens. *Carinaria Me-*

diterranea, then, may afford another instance of the inconvenience of a specific name adopted from the locality where a specimen has been taken. Lamarck's *Carinaria cymbium* (if indeed it be a *Carinaria*, see the figure referred to in Quallieri, tab. 13, fig. D.) is microscopic, no bigger than a grain of sand, *de la taille d'un grain de sable*.

Geographical Distribution of the Genus.—*Carinaria* has never yet been taken in any other than warm latitudes. Three species, *C. vitrea*, *C. fragilis*, and *C. Mediterranea*, are recorded without reckoning Lamarck's *C. cymbium*.

The above is copied from the *Iconographie de Cuvier's Animal Kingdom*, and represents the *Carinaria* with its back uppermost. It is denominated *Carinaria cymbium*, but there can be no doubt that it is *Carinaria Mediterranea*.

We have little doubt that the animal of Argonauta will be found to bear a strong resemblance to *Carinaria*. [CERPHALOPODA. PAPER NAUTILUS.]

CARINTHIA (in German, *Kärnten*), a duchy of the Austrian empire, constitutes the northern part of the government of Laibach, and is comprehended in two of its subdivisions, the circles of Klagenfurt, formerly Lower Carinthia, and Villach, formerly Upper Carinthia. On the E. and N.E. it is bounded by Styria, on the N.W. by Salzburg, on the W. by the Tyrol, and on the S. by the Friaul and the circle of Laibach. It is situated between 46° and 48° N. lat., and 12° and 15° E. long., and occupies an area of 3180 square miles. Its northern and southern districts, between which the valley of the Drave runs from W. to E., are Alpine regions; the land enclosed between these enormous masses does not enjoy the light and heat which are indispensable to successful cultivation, and the produce of the soil is insufficient for the population. The valleys between the mountains contain, however, a deep soil of sand and clay intermixed, and are very productive. Of the two mountain chains which encompass this duchy, the formation is wholly dissimilar: the northern, in its whole length, is composed of granite, gneiss, and other primitive rocks, which are not unfrequently traversed by beds and strata of quartz, sulphate of barytes, and various species of ores. This chain also contains the most elevated summits in Carinthia: the 'Glockner,' which is close to the point where its border meets the boundaries of Salzburg and the Tyrol, and has an elevation of 12,980 feet, is the highest of the Carinthian mountains. The eastern districts are bounded by the Carniolan Alps, which are much inferior in height not only to the north range but to that part of the Alps which form the bulwark of Carinthia in the south. The most remarkable feature in these Carniolan Alps is that portion called the 'Dobratsch,' or Villach Alps, whose elevation averages about 7500 feet, along the side of which runs a fine plateau. The vegetation of the highest points in this chain is confined to stunted grass, Iceland moss, and other plants resembling the vegetation of the most northerly parts of Europe.

Carinthia is richly supplied with streams. The Drave, which receives most of the rivers, enters the duchy from the Tyrol and flows for about 140 miles from W. to E., through Carinthia. The other large rivers which water it are the Gail, Möll, Liser, Gurk, Glan, and Lavant. Carinthia is full of mountain streams, such as the Loibl, Feistritz, Missling, and Fella, which flow northwards into the Drave. The duchy abounds in lakes, among which are the Worthsee near Klagenfurt, the Ossachersee, and Mühlstadtersee, both of which issue from the Drave; the Weissensee, the Faakersee, and lesser Raiblsee.

The natural disadvantages under which Carinthia labours cripple its agricultural industry. The arable land scarcely exceeds 200,000 acres, and the produce is not estimated at more than 35,000 quarters of wheat, 120,500 of rye, 48,800 of barley, and 67,300 of oats. But the land is proportion-

much richer in meadows and pastures, the former estimated at 371,430 acres, and the latter at 521,428. A of animals when last taken amounted to 15,956 horses, 38,482 oxen, 77,726 cows, and 129,120 sheep. The breed of horses is much finer in Upper than in Lower Carinthia, but in the latter the breed of horned cattle is superior. The wool is of an ordinary description. Swine and goats are reared in most parts. So small a portion of the soil is laid out in garden-ground that the whole quantity is not calculated at more than about 3000 acres; and that occupied as vineyards, which are confined to Lower Carinthia, does not amount to more than about 320 acres, or exceed an average annual produce of 20,000 gallons of very inferior wine. The woods and forests cover about 570,000 acres; but until of late years they have been so much neglected that they have not yielded sufficient for the consumption of the country.

The mines of Carinthia constitute its chief wealth. The main chain of the Alps contains various metals in combination with ores, earths, sulphur, &c., and is more particularly rich in copper and iron. The circle of Klagenfurt abounds in lead and zinc. The mines of Fragant in Upper Carinthia contain inexhaustible supplies of copper; but, owing to the hardness of the stone from which it is necessary to extract it, and the scarcity of fuel in the vicinity of the mines, the yearly produce is not more than about 800 cwt. This metal is also raised at Kerschdorf in the circle of Villach, and on Mount Lumberch, in that of Klagenfurt. Iron ore occurs through the whole length of the Alpine chain, from the confines of the Tyrol in the W. to those of Styria in the E.; but the same natural impediments which occur with regard to copper circumscribe the value of the resources which Carinthia possesses in its iron. The principal mines at work are at Döllach, Gmünd, Freisch, Hüttenberg, where there are 18 high-blast furnaces, Waldenstein, and St. Gertaud; the produce of the whole duchy however is computed not to exceed 13,000 or 14,000 tons. In all the Austrian dominions there are no lead-works so extensive and productive as those of the 'Ore-mountain' (Erzberg), close to the Lead-mountain (Bleyberg), at no great distance from Villach in Upper Carinthia; they yield a yearly supply of between 16,500 and 17,000 tons of pure lead; the mines on the Raibl produce about 500 tons annually, and there are others in the same circle, but on a smaller scale, on the Kellerberg, at Döllach, &c. In Lower Carinthia (or Klagenfurt), the mines at Ebnach, Schwanbach, and Windisch-Bleyberg produce about 500 tons per annum. The produce of the whole duchy is about 25,000 tons. The largest zinc and calamine works are situated on the Raibl in the southern part of Upper Carinthia; these and some minor works in the duchy yield about 400 tons of ore yearly. Some silver was formerly obtained at Menselding near Strassburg, and quicksilver at Windisch-Capel and Döllach; on the Raibl, and in the iron strata at Hüttenberg, antimony is found. Immense beds of coal exist in Carinthia, but Gottaring and St. Leonhard are the only spots where they have been much turned to account. Large quantities of turf or peat are dug at Feldkirchen and at Loretto on the Worthsee. Carinthia abounds in stones of various kinds, some of which are valuable. It contains quartz, jasper, semi-opal, garnet, beryl, &c., as well as various kinds of clay, talc, limestone, &c. There are marble quarries at Velden, Uppervillach and Wasserleonburg in Upper, and at Sittersdorf, &c., in Lower Carinthia.

The population of this duchy is estimated at about 290,000 souls, of whom 124,000 in Upper Carinthia (1494 square miles) and 166,000 in Lower Carinthia (1086 square miles.) They are of two distinct extractions, the German and the Wend or Vandal; the proportion of the former to the latter is as 172 to 95, and their dialects are totally dissimilar. The increase in the number of inhabitants has not been very rapid, for, in 1816, they amounted to 267,015; in 1820 to 271,946; and in 1825 to 287,342.

The operative industry of this duchy is mostly limited to the working up of the raw materials which it produces; the manufacture of iron and iron ware holds the first place. Besides the 18 furnaces at Hüttenberg, there are 2 high-blast furnaces in Upper Carinthia; in the two circles there are likewise 61 flating-mills, and steel and iron-plate works, &c. The whole quantity of iron and steel made in the duchy is estimated at 130,600 cwt., of which about 37,500 are of steel. The other manufactures

consist of two manufactories of woollens, one of silk stuff and fine cotton prints, several of ribands, and cottons, and a white-lead work; the greater part at Klagenfurt, the capital of Carinthia. Independently of what has been enumerated, the duchy has few products to export, beyond horned cattle. Its internal communications are much facilitated by good roads, among which there is a skilfully constructed one across the steep and rocky Loibl into Carniola.

Carinthia possesses 11 towns, 25 market-towns, 2763 villages, and about 47,000 houses. It has been considered as one of the German possessions of the Austrian crown ever since it became an appendage of that crown in the middle of the fourteenth century. It has states of its own, consisting of four sections, namely, the bishops and dignitaries of the church, the aristocracy, the equestrian order, and the representatives of towns and places with markets. The executive power, immediately dependent upon the central government in Vienna, is exercised by the chief board of administration (*Gubernium*, literally government) at Laibach, and the head administrative authorities in the duchy itself are the provincial boards at Klagenfurt and Villach. Subordinate to the latter are 70 district commissionerships in Lower, and 14 in Upper Carinthia. The majority of the inhabitants profess the Roman Catholic religion, and the bishops of Gurk (at Klagenfurt), and of Lavant (at St. Andrä), are superintendents of all ecclesiastical affairs. The Lutherans, whose numbers amount to about 20,000, chiefly inhabit Upper Carinthia, and are within the secular jurisdiction of the consistory at Vienna.

CARINUS, MARCUS AURELIUS, succeeded to the throne conjointly with his brother Numerianus, after the death of their father Carus, at the beginning of A. D. 284. (Crevier, *Histoire des Empereurs Romains*.) His conduct at Rome during the absence of his father had been marked by licentiousness, cruelty, and extravagance. His brother Numerianus, whose character was good and mild, having been murdered by Aper on his return from Persia, the soldiers elected Diocletian, a soldier of fortune, who immediately put Aper to death. Diocletian then marched against Carinus. Carinus collected the troops that were in Italy, and went to meet Diocletian. The two armies met in the plains of Mœsia, near Margum and Viminacum. Carinus had at first the advantage, but many of his own officers, who detested him for his brutal conduct, rose against him, and killed him during the action. The two armies then ceased the fight, and proclaimed Diocletian sole emperor, A. D. 285.

Coin of Carinus.

[Brit. Museum. Actual Size. Silver. 29 grains.]

CARLI, GIOVANNI RINALDO, was born in 1720, of a noble family at Capo d'Istria, in the Venetian territory. He studied first at home, and afterwards at Flambro in the Friuli, where he applied especially to the mathematical sciences. At the age of twenty-four he was appointed by the Venetian senate professor of a new chair of astronomy and navigation established at Padua. He invented several improvements in ship-building for the Venetian navy, and had the superintendence of the naval school at Venice. After seven years he resigned his chair and returned to Istria, to attend to the management of his private affairs. During this time he visited the antiquities of Pola, which he afterwards detailed at length in his work on Italian antiquities. He had for a companion in his researches the naturalist Vitaliano Donati, whose work on the natural history of the Adriatic was edited by Carli after the author's death: 'Saggio della Storia Naturale Marina dell' Adriatico,' 4to., Venezia, 1750. In 1754 Carli published the first volume of his great work, 'Delle Monete e della Istituzione delle Zecche d' Italia' (On the History of the Coins and Currency), and on the Institution of the Mints of Italy). The second volume appeared in 1757, and the third and fourth in 1760. Carli employed nine years in the completion of this work, during which he inspected the cabinets of medals and the archives of Milan, Turin, Tuscany, &c. A new edition, with corrections and additions by the

author, was published at Milan in 1765, in 7 vols. 4to. Carli begins the monetary history of Italy with the mint of Odoscar at Ravenna, after the fall of the Western Empire, and comes down as far as the seventeenth century, describing and illustrating the numerous coins, national and foreign, which were current in Italy during the intervening ages; their weight, title, legends, and relative value, and also their value compared with the price of provisions at different epochs. He treats also of the commerce of bullion, and of the frequent alterations and deteriorations which took place in the weight and intrinsic value of the currency; he considers the whole subject both in its economical and legal aspect. Carli demonstrates, among other things, that the quantity of the precious metals in Italy was considerably greater in the fifteenth century, before the discovery of America, than in the eighteenth, and that the real price of provisions was proportionately higher; an assertion which appeared quite novel at the time, because the nominal price of provisions appeared higher at the latter period, owing to the intrinsic value of the coin being much lower than it had been formerly. In the fifteenth century every petty state of Italy had its mint at work; the mint of Venice alone, under the Doge Mocenigo, coined yearly 1,000,000 of gold sequins, besides 200,000 sequins in silver coins. All this is explained by the fact, that Italy was then the most commercial country in Europe; and it serves to confirm the accounts of the prodigious wealth of Italy previous to the French and Spanish invasions in the beginning of the sixteenth century, of which wealth the innumerable palaces, churches, paintings, and other monuments of splendour and luxury still remaining in that country are sufficient evidence.

In his 'Ragionamento sopra i Bilanci economici delle Nazioni,' Carli asserted, against the then received opinion of the economists, that the balance of trade between nation and nation proved little or nothing as to the real prosperity of each. He was also at variance with the economists in his dissertation 'Sul libero Commercio dei Grani,' addressed to Pompeo Nero in 1771, in which he combated the general application of the principle of the freedom of the corn trade under all circumstances. He considered it as a question more of administration than of commerce. He quoted the example of Poland, Hungary, Sicily, Apulia, Egypt, &c., which countries produce and export enormous quantities of corn, and yet always remain poor. Another interesting work of Carli is his 'Relazione sul Censimento dello Stato di Milano.' The censimento or catasto was a survey and valuation of all the lands of Lombardy, effected under Maria Theresa, and completed in 1759 for the purpose of equalizing the land-tax and other public burthens. The plan was afterwards imitated in Prussia under Frederick II., in France under Napoleon, and in other countries. At the same time a liberal municipal system was established in Lombardy, by which every commune had its council consisting of all the proprietors inscribed in the censimento, which council deliberated upon communal affairs, made out the yearly budget, and appointed five deputies or administrators of the communal property. This system has continued in Lombardy to this day.

Carli was appointed president of the new council of commerce and public economy established at Milan as well as of the board of public studies. In these capacities he repaired to Vienna in 1765 to confer with the minister Kaunitz, and was received at court with great distinction. When Joseph II. went to Milan in 1769 he appointed Carli his privy councillor, and it was at Carli's suggestion that the emperor finally abolished the tribunal of the Inquisition, which had existed at Milan for centuries. In 1771 Carli was made president of the new council of finances, which made useful reforms in that branch of administration. His labours having seriously impaired his health, he resigned the presidency of the council of commerce, and devoted his time chiefly to complete his 'Antichità Italiane,' which appeared in 1788, 5 vols. 4to. Notwithstanding its general name the work is chiefly engrossed by the antiquities of Istria. Carli being now old and infirm, the emperor Leopold II. restored to him the whole of the emoluments which he had enjoyed when in the full exercise of his office. He lived some years longer, and died in February, 1795, leaving behind him the reputation of an enlightened economist, a learned archaeologist, and a virtuous magistrate. He published many other works, among which are 'Lettere Americane,' in which he investigates the antiquities of America, and refutes Pauw's assertions in disparagement of

the natives. In his *L'Uomo Libero* (1838) he combats the doctrine of natural liberty: this is perhaps the best illustration of the *Contrat Social*. He wrote also *Storia della Letteratura Italiana*, *Della Patria degli Italiani*, *Indole del Popolo Italiano*, besides many dissertations on classical subjects, on the tritoxism of the Argonauts, on Hesiod's Theogony, on the geography of the antients, &c. He wrote also a defence of Paolo Vergerio, bishop of Capo d'Istria, who was condemned as a heretic by Pope Paul III.; a refutation of Tartarotti, who even in Carl's time asserted the existence of sorcery; several poetical compositions, and a letter on the gout, in which he describes a new remedy which he had discovered for that disease. Carl's works were published in 19 vols. 8vo. Milan, 1784-94, exclusive of his *Italian Antiquities*. He left also many works in MS. (*Ugoni, Storia della Letteratura Italiana*; *Pencina, Storia dell'Economia pubblica in Italia*; *Bossi, Elogio Storico di Gian Rinaldo Carli*.)

CARLISLE, an ancient city, parliamentary and municipal borough, and port, in Cumberland, 260 miles N.W. by N. from London direct distance, or 302 by the road. Carlisle is supposed to be of British origin, and there is reason to conclude that it was a Roman station, the *Luguvallum* of the *Itinerary of Antoninus*. Its modern name is said to be derived from the word *Luel*, a Saxon corruption of *Luguvallum*, to which the British word *Caer* is prefixed. It appears to have been first fortified about the time, probably, of Agricola. The Danes destroyed it about the end of the ninth century; and it remained desolate till after the Norman conquest. Its restoration, and the erection of the castle, are attributed to William Rufus. The subsequent history of Carlisle, down to the junction of the two kingdoms, is intimately connected with the wars between England and Scotland, and the history of the border feuds and forays. Carlisle was taken by David I. king of Scots, and besieged afterwards by William, called the Lion, who did not succeed in his attempt. It suffered repeated damage by fire during subsequent sieges. It was occupied on different occasions by Edward I., who, in 1306-7, held a Parliament here, at which was passed the act printed amongst the statutes of the realm under the title of 'the Statute of Carlisle.' Mary, Queen of Scotland, stopped in her flight after the battle of Langside at Carlisle, from which period commenced her long imprisonment in England. It suffered severe privations during the civil wars, having declared for Charles I. In 1745 the garrison surrendered to Charles Stuart, the mayor and corporation presenting him with the keys of the city on their knees, and afterwards proclaiming him King of Great Britain. On the city being re-taken by the Duke of Cumberland, the principal actors on this occasion suffered, some of them death, others severities little short of it.

Carlisle, as an important border-town, was early endowed with peculiar privileges: but down to the year 1745, no trade or manufacture was carried on in it of the smallest importance. Being a fortified city, and a place of retreat to the surrounding inhabitants, it was, at different periods in its early history, very populous; but after the junction of England and Scotland, under James I., it sunk into decay, from which it has only begun to recover since the commencement of the present century. The population in 1763 was about 4158; in 1780, 6299; in 1801, 10,221; in 1831, the total population amounted to 19,069.

Carlisle is divided into the ancient city and the suburbs, which make together the city popularly so called. The ancient city was formerly the parliamentary borough; but under the Reform Act, a large portion of the suburbs was included. The number of voters on the registry at the last general election (1834) was 946. The suburbs contain a larger population than the ancient city, and about an equal number of houses. Under the Municipal Reform Act the town is divided into five wards, with ten aldermen and thirty councillors. Carlisle has returned two members to Parliament since the time of Edward I.

The principal business of Carlisle consists in its manufactures of cotton goods and gingham, and in a coasting trade. Some traffic arises also from its lying on the great western road from London to Edinburgh and Glasgow. In 1823 a steamboat was completed from Carlisle to Bowness, on the Solway Firth, a distance of eleven miles, by means of which vessels of 20 and 40 tons can come up to the town. There is now frequent communication between Carlisle and

steam-vessels. Considerable expectations of traffic are entertained from a rail-road now in progress between Newcastle and Carlisle, which was opened between Newcastle and Blenkinsop, in July, 1846. The following is a statement of the amount of tonnage of the port of Carlisle in three different years:—

	Coastwise		Foreign	
	Inwards.	Outwards.	Inwards.	Outwards.
1823	14,220	7,908	2,159	719
1828	23,384	18,440	2,666	384
1832	22,820	23,392	2,739	741

The increase of late years in Carlisle has been considerable: the new streets are comparatively wide and hand some, and the roads approaching the place are excellent. The town is very healthy. The mean quantity of rain at Carl. for 24 years, 1801—1824, was 30.571 inches. The mean height of the barometer for 24 years, 29.839 inches. The mean temperature for ditto, 47.453°.

Carlisle is pleasantly situated on an eminence, nearly enclosed by three streams. The largest of these, the Eden, runs past the city in a N.W. direction into the Solway Frith; the other two, the Caldew and the Pettrel, fall into the Eden on the W. and E. sides of the city respectively. A handsome elliptical bridge of five arches, and of white freestone, was erected over the Eden in 1812, at an expense of 70,000*l*. Two stone bridges, of one arch each, are thrown over the Caldew, and one over the Pettrel of three arches, about a mile from the town.

Before the Reformation, there were several ecclesiastical establishments in the city. In the year 1133 Henry I. erected Carlisle into a see, giving its bishop jurisdiction over a large portion of Cumberland and Westmoreland. In the third Report of the Church Commissioners (May, 1836) amongst other alterations suggested respecting the see, it is proposed that the bishopric of Sodor and Man should be united to that of Carlisle. There is but one archdeaconry in the see. Dr. Paley was archdeacon of Carlisle, and published some of his most popular works while residing in the city. He is buried in the cathedral, where a monument has been recently erected to his memory. The cathedral is an ancient building of red freestone, displaying specimens of different styles of architecture, some parts of which are assigned to the Saxon times. In addition to the cathedral and St. Mary's, there are three other churches,—St. Cuthbert's, Trinity, and Christ Church.

An earldom of Carlisle was created shortly after the Norman conquest. It has become three times extinct, by surrender, attainer, and death without issue. The present earldom was revived in 1661, and is held by a branch of the Howard family.

The castle of Carlisle lies between the city and the Eden, on a slight eminence overlooking the river. It is still maintained as a garrison-fortress. Scarcely any portion of the old walls and bulwarks of the ancient city now remains: a great part of the city walls, and the English, Scotch, and Irish gates, recently removed to promote the health and convenience of the inhabitants. There is no city gaol. The county gaol and county house of correction are within the city; they were finished in 1827.

There is an endowed grammar-school in Carlisle, founded by Henry VIII.; the number of other schools, as given in the Education Returns for 1835, is 47.

The city also contains a number of charities and benevolent institutions: among which are an Infirmary, lately erected, a Fever Hospital, a Dispensary, and a Humane Society. There are also two literary institutions.

The market-days are Wednesdays and Saturdays. There are fairs held in August and September, persons attending which were antiently exempted from all arrest. (*Communications from Carlisle, &c.*)

CARLOS, DON. [PHILIP II.] CARLOVITZ (Carlovacze, Hungary), a well-built town which extends from the E. foot of the mountains which surround it to the banks of the Danube, a little to the S.E. of Peterwardein; it lies in what is termed the Captancy or Military Frontiers of Sclavonia. It is the seat of the archbishop or metropolitan of the Greek church in Hungary, and of a Greek consistory and chapter. The only quarter of Carlovitz which has the appearance of a town is that part which adjoins the archiepiscopal palace; the larger portion of it stretches, like a lengthened regularly laid out village, along the banks of the Danube. It contains a cathedral, three churches, a Greek theological seminary, a

lyceum in much repute, a Roman Catholic academy, and an hospital. The number of houses is about 500, and of inhabitants about 5900; in 1805 the population was 4841, and in 1816, 5797. The archbishop is the only Greek prelate of that rank in the Austrian dominions, and the whole of the Greek clergy within them are subject to his jurisdiction. The church of Mariatried on an adjacent eminence is built upon the spot on which the treaty of 1699, between Leopold II. and his Polish and Venetian allies and Mustapha II. of Turkey, was concluded. The traffic of the place is derived from its fisheries and transit trade, as well as the export of the wines, which the environs produce in considerable quantity; this has in some years amounted to 1,800,000 gallons. 45° 10' N. lat., 20° 10' E. long.

CARLOW, an inland county of the province of Leinster and diocese of Leighlin in Ireland, bounded on the E. and S.E. by the counties of Wicklow and Wexford, which separate it from the Irish Channel; on the S.W. and W. by the county of Kilkenny, and on the N.W. and N. by Queen's County and the county of Kildare. Its greatest length from N. to S. is 29 English miles; breadth, E. to W., 20½ do.; area, 346 square miles, or 211,410 statute acres; gross population, 1821, 78,952; in 1832, 81,649.

The county of Carlow (the smallest county, excepting Louth, in Ireland) is in form nearly triangular, the directions of the angles being N.N.E., W.S.W., and S. respectively. The whole county may be considered as an extension of the great central plain of Ireland, running S. to a point between the Wicklow and Wexford Mountains on the E., and the high grounds known as the ridge of Leinster on the W., and traversed in a direction nearly parallel to its E. side by the Barrow, which after cutting off the barony of Idrone West, changes its course from S. to S.S.E., and constitutes the W. boundary of the county, until it leaves it at its meeting with Kilkenny and Wexford. The Barrow has been made navigable through its whole course in Carlow, and affords the means of a considerable export trade to Carlow, the assize town, which is situated near this river's entrance into the county. The great S. road from Dublin to Kilkenny passes through Carlow in a direction nearly parallel to the Barrow, which it crosses at Leighlin Bridge. The roads, which are numerous and mostly in good repair, are kept up by county presentments, and, excepting the above line, have no turnpikes. A railroad has been projected nearly in the line of the chief S. road which connects Carlow with Dublin and Kilkenny. At present Carlow derives its chief facilities of transport from the Barrow navigation, which affords a water-carriage S. to Waterford, and N. by the Grand Canal, a branch of which meets it at Athy, to Dublin and the Shannon. The great plain, of which the county of Carlow may be considered as an extension, consists of limestone, which occurs along the basin of the Barrow and occupies the greater portion of the W. baronies. On the extreme W. of the county however the coal formation of the Castlecomer district occupies a segment near Old Leighlin, while the E. portion of the county is a field of granite, extending from the great granite chain of Wicklow and Wexford. A tongue of the old red sandstone formation of the Waterford Mountains is intruded between the limestone and granite, and crosses the bed of the Barrow about the point where it becomes the county boundary, striking N. towards Bagenalstown. In the limestone district the soil is gravelly but warm; it is lighter and more peaty in the granite district. The limestone is dark, close-grained, and well adapted for the purposes of building; and the granite is celebrated for its whiteness, durability, and easy working under the hammer. From the facility also of splitting this stone with the wedge, lintels of granite are commonly employed in cases where bars of wood are used elsewhere, and a common fence in the county of Carlow is a granite paling, the square lintels resting on their angles in notches on the tops of granite uprights: the weight of the stone keeps it in its place without any further fastening, and its hardness renders it the most lasting of all inclosures.

With the advantages of a good soil and the most uniformly resident proprietary in Ireland (the rental of the proprietary is estimated at 130,000*l.* per annum), Carlow has long held a corresponding position as an agricultural and productive county. The crops generally raised are potatoes, wheat, barley, and oats, the proportion of each being pretty much in the order in which they are here enumerated. The usual rotation is potatoes succeeded by wheat; that

again by oats or barley, with grass-seed and clover, to be kept for mow and grazing, for a longer or shorter time as may be convenient to the holder. The system of farming in a great part of Carlow may be said to be good, particularly in the neighbourhood of Carlow, Leighlin Bridge, and Bagenalstown; and a decided improvement has latterly taken place throughout the county, that part of it bordering on Wexford and the lower part of Kilkenny being the most backward. In the first-named districts turnips and other green crops are freely cultivated, and the practice of ploughing in the second crop of clover is generally pursued. On the whole, the county is a rich one, and the farmers, whether on a large scale or not, are, for their stations, generally comfortable. The land is chiefly held in fee, averaging 15*s.* per acre to proprietors, and 40*s.* per acre to occupiers.

Carlow is divided into six baronies, viz., Rathvilly and Carlow on the N.; Forth, Idrone East, and Idrone West in the centre, and St. Mullins on the S. The chief towns are, in Carlow, Carlow, the assize town of the county; in Rathvilly, Tullow and Hacketstown; in Forth, Clonegal; in Idrone East, Leighlin Bridge, Bagenalstown, and Borris; in Idrone West, Old Leighlin. None of these are of any importance as towns, except Carlow; Leighlin Bridge however is a place of considerable interest to the antiquary, with a population of upwards of 2000; and Bagenalstown is likely to become one of the most flourishing villages in Ireland. The only corporate towns in the county are Carlow and Old Leighlin, which formerly returned two members to the Irish parliament. The latter place is now a hamlet of some twenty cabins.

The manufacture of coarse woollens was at one time carried on to some extent in Carlow, but the trade is now altogether gone, and neither linen nor cotton spinning has yet been introduced. The county is essentially an agricultural one, and its staple is the raising and manufacture of provisions—especially corn, butter, flour, and oatmeal. The export of corn from this county may be judged of by the tables given under BARROW. The export of butter from Carlow town alone has varied, within the last ten years, from 25,000 to 35,000 firkins, averaging 70 lbs. weight of butter each, to which may be added 10,000 firkins more for the remainder of the county, shipped annually by way of Waterford. On the Barrow navigation there is a fall of rather more than one foot per mile, which gives a great water-power, available for mill sites, at almost every weir; the number of corn-mills along the line is accordingly very great, and, with one or two exceptions, these establishments lie within the limits of this county. Corn-mills in Ireland are generally large edifices, and many of those in the county of Carlow belong to the first class of such buildings. Along the Carlow bank of the Barrow (with the above exception) it is calculated that not less than 200,000 barrels of wheat (producing 350,000 cwt. of flour, at an average price of 13*s.*) and 100,000 barrels of oats (producing 100,000 cwt. of oatmeal, at an average price of 11*s.*) are annually manufactured; an amount nearly double that effected by the same power ten years ago. The increase is chiefly owing to the great improvements in milling machinery which have taken place within that time. The provision trade consists chiefly in bacon for the home market. Large quantities of barley are malted by the resident maltsters and distillers. The value of the landed produce of Carlow has been estimated at 1,038,000*l.* per annum.

The first event of historical interest connected with this county took place A.D. 630, when a synod was held at Old Leighlin to adjust a dispute which had arisen between the Irish ecclesiastics and the see of Rome regarding the fit time of celebrating Easter. Of this discussion the life of St. Munnu, quoted by Ware, furnishes the following characteristic anecdote:—Lasarian, abbot of Leighlin, who presided over 1500 monks, defended the new (*i.e.* the Roman) order: while others adhered to the ancient (*i.e.* the Irish) form. * * * Then St. Munnu (Lasarian's opponent) said—"You have three options given you, O Lasarian: let two monks, one of the old order and another of the new, be cast into the fire, and let us see which of them shall escape from the flames. Or let two monks, one of yours and another of mine, be shut up in the same house, and let the house be set on fire, and we shall see which of them shall escape unhurt. Or let us both go to the sepulchre of a dead monk and raise him up to life, and he will show us which order we ought to observe in the celebration of

Easter. To which Lasegan answered—"We will not proceed to judgment with you; because we know that if you command *Mount-Murgh* (*Shumargy*, near Carlow) to be changed into the *White-Field* (Leighlin), and the *White-Field* to be removed to the place where *Mount-Murgh* now stands, that on account of your infinite labours and great charity God would immediately do this for your sake." Afterwards the people returned every one to their own homes. The synod ended by decreeing a deputation to Rome, where after diligent inquiry the Irish ecclesiastics became satisfied of the correctness of the Roman computation, and, returning, introduced it universally in Ireland. The civil history of the county up to the arrival of the English possesses little or no interest. On the arrival of the English this part of the country was known as comprehending the territories of Hy-Drone and Hy-Cavanagh, being the northern portion of the territory of Hy-Kinsellagh, the patrimony of Dermot Mac Murrough, king of Leinster, the inviter of Strongbow. Isabel, daughter of Strongbow by Eva, daughter of Dermot, married (1189) William Earl Marshal, one of the invading nobles, who in her right succeeded to the principality of Leinster. This William, who was Lord Justice of Ireland, granted the first charter to the inhabitants of Catherlagh, as the present county town was then called, about 1208; and King John coming to Ireland in 1216 made the county shire ground. William Earl Marshal and Pembroke dying in 1219 left five sons and five daughters, and on failure of the male line his unmorse estates devolved upon the latter, viz., to Maud, who married Roger Bigod Earl of Norfolk, Carlow; to Joan, who married Warren Lord Montchesney, Wexford; to Isabella, who married Gilbert Earl of Gloucester, Kilkenny; to Sibilla, who married William Earl Ferrers and Darby, Kildare; and to Eva, who married William de Breos Lord of Brecknock, Leix, part of the present Queen's County; which great partition was made between the co-heiresses at Woodstock on the 3rd May, 31st Henry III. From Roger Earl of Norfolk the lordship of Carlow passed to the crown, and from Maud his wife the barony of Idrone passed by grant in fee to the family of Carew. The lordship of the county was next granted by Edward I. to Thomas de Brotherton, and from him descended through the family of Howard, earls of Norfolk and lords of Carlow, till forfeited by the statute of absentees in the reign of Henry VIII. These lords palatine are thus described by Sir John Davies. "These absolute palatines did make barons and knights, did exercise high justice in all points within their territories, erected courts for criminal and civil causes, and for their own revenues, in the same form as the king's courts were established in Dublin; made their own judges, senechalls, sheriffs, coroners, or escheators; so that the king's writ did not run in these counties, but only in the church lands lying within the same, which were called the cross, wherein the king made a sheriff; and so in each of these counties palatinate there were two sheriffs, one of the liberty and one of the cross." But these lords residing at a distance gradually slackened the exercise of their privileges, and the descendants of the dispossessed Irish taking advantage of the lax administration of their deputies, and headed by one of the Kavanaghs, a descendant of Dermot Mac Murrough, began forcibly to repossess themselves of their ancient patrimony, in which attempt they were ultimately so successful that in the 37th Edward III. an order issued *pro barrio amovendo a Catherlogh usque ad Dublin*—for withdrawing the boundary of the pale from Carlow to Dublin—the country S. of Naas having fallen completely into the hands of the Irish. Richard II., A.D. 1394. and again in 1399, undertook expeditions* for the recovery of the revolted counties, but although he forced some of the Irish chieftains to a temporary show of obedience, he was finally obliged to return to England without accomplishing his object. The whole county, including Carlow town and castle, seems to have remained in the hands of the Kavanaghs and other native chiefs till 1494, when the Fitzgeralds seized the castle, which they held till after the unsuccessful rebellion of Lord Thomas Fitzgerald in 1537. In this year the resumption of the lordship of Carlow, alluded to above, took place; by which means the crown was afterwards enabled to grant large estates to the family of Butler in this county. In 1567 Sir Peter Carew, descendant

of the last proprietor of Idrone, into which the Kavanaghs had forcibly intruded in the reign of Edward III., exhibited his claim to this barony, and having established it to the satisfaction of the council, entered on possession, and dealt in such good order with the Kavanaghs, and so honourably used himself, that they all voluntarily yielded up their lands, and submitted themselves to his devotion. (Hooker.) He appears to have been a great benefactor to this part of the country, having divided the barony into manors, and established manor-courts for determining causes according to the English law, keeping a strong force at Leighlin Bridge, where he was celebrated for his splendid hospitality, and overawing while he conciliated his turbulent neighbours. Sir Peter Carew died 1576, and his son Sir Peter Carew was killed at Glendalough in a battle with the O'Byrnes of Wicklow in 1580, after which the Kavanaghs once more made head in Carlow, and Donnell Spaniagh (the Spaniard), their leader, joining with Feagh Mac Hugh, chief of the O'Byrnes, commenced a predatory warfare, which lasted from 1590 till 1601, when Sir Oliver Lambert at length reduced both to submission. During this insurrection Kavanagh had upwards of 1000 men of his own name in the field; and after his submission furnished a small force of his own people against Tyrone, in aid of whose great rebellion he had originally risen in arms.

During the reign of Elizabeth large tracts of the county of Carlow had been granted to the Butlers and Fitzgeralds, and in the succeeding reign their estates were confirmed, as well as considerable possessions to the Earl of Thomond, to the submitted Kavanaghs, and among other grants was that of the entire barony of Idrone, which seems to have escheated, on Sir Peter Carew's death, to the family of Bagnall. The forfeitures consequent on the different wars up to 1690 did not make any very material change in the distribution of property, the attainted proprietors in this county being few in number. Dudley Bagnall, Esq., was the chief sufferer, and the distribution of his estates, with those of John Warren, Esq., John Baggot, Esq., and Lord Galmoy, introduced a few new names, still of great respectability, into the county. The total amount of forfeitures in 1688 was 26,303 Irish acres, valued at that time at 7913*l.* 11*s.* 6*d.* per annum. In the rebellion of 1798 Carlow was the scene of several engagements. On the 25th May the rebels attacked the town of Carlow, and were repulsed with the loss of 600 men; on the same day a battle was fought at Hacketstown, in which the insurgents, said to have been 13,000 strong, were defeated with considerable loss; and, on the night preceding, Borris House, the residence of Mr. Kavanagh, was attacked by 5000 of the peasantry, who were repulsed both on this occasion and on the 24th June when they assailed the town of Borris. Leighlin Bridge and Bagenalstown were also attacked with a like success. The amount of compensation claimed for losses sustained in this rebellion by the county was 24,554*l.* 14*s.* 7*d.* The county has, during the earlier part of the present century, enjoyed the advantages of resident landlords and an attached peasantry, but of late years society has been much torn by dissensions both civil and religious.

The chief antiquities of the county are military; cromlechs, near the towns of Carlow and Hacketstown, and the cathedral church at Old Leighlin, being the only pagan and ecclesiastical monuments of interest. Of the cromlechs that near Carlow is the most remarkable: the covering-stone here weighs nearly 90 tons. Of the castles those at Carlow, Tullow, and Leighlin Bridge, are the most ancient—the building of all is attributed to De Lacy. At Clonmullin, in the barony of Forth, are some traces of the castle of Donnell Spaniagh Kavanagh; Cloughgrenan, a castle of the Butlers on the right bank of the Barrow, is still standing. Clonmore, another stronghold of the same family, situated near Hacketstown, remains in a state of good preservation; it is a noble pile of 170 feet square, flanked with square towers at the angles.

In 1821 the number of young persons receiving instruction in this county was 7059; in 1824 there were 166 schools, educating 8461 scholars, of whom 7000 were Roman Catholics, and 1461 were Protestants.

The county expenses are levied by annual grand jur assessments. The only public institutions for charitable purposes are a lunatic asylum, fever hospital, and infirmary at Carlow, dispensaries at seven other towns throughout the county, and fever hospitals at Tullow and Bagenalstown. Poverty does not assume the same dreadful form here as in

* The proceedings of the English army in the last expedition are minutely detailed in the MS. of De la Marquis, who accompanied the king on the occasion. The MS. has been translated and published in the "Archæologia."

many other counties of Ireland; still it would appear, from the reports on the state of the Irish poor, that although the more distressed classes in Carlow neither emigrate periodically to England, nor willingly betake themselves to open begging, there is a great amount of suffering among the labouring peasantry during the winter months and from June to August annually. Women of loose character are scarcely known in the country parts, and persons of illegitimate birth labour under considerable odium.

In 1831 the population consisted of 41,839 males, and 81,988 females, total 123,827 persons, constituting 14,609 families, of which 8163 were employed chiefly in agriculture, 2581 were engaged in trade, manufactures, and handicraft, 56 individuals being employed in machine making, and 3865 not included in either class. Number of houses inhabited, 13,275; uninhabited, 395; building, 109; total, 13,779; do. in 1832, 13,906; do. in 1821, 13,028.

Carlow county returns two members to the imperial parliament, and supports two newspapers, both published in the county town, which returns one member.

The history and antiquities of the county have lately been illustrated in a work on that subject by Mr. Ryan, which furnishes all the historical facts of importance. For statistical and geographical details see *Stat. Survey of the County of Carlow; Parliamentary Papers and Reports; Trans. Geol. Society*, vol. v. This portion however of the present notice is chiefly derived from actual observation.

CARLOW, the assize town of the county of Carlow, situated in the parish and barony of the same name, 50 English miles S.W. from Dublin. The boundaries of the ancient borough, including only that portion of the town which stands upon the left bank of the Barrow, have been extended by the 2d and 3rd Will. IV., c. 89, and now embrace the suburb of Graigue, in the Queen's County, on the right bank of the river; the extent of the ancient borough is 382 statute acres, and that of the additional portion 114 acres, with a total population of 10,612 persons.

The town of Carlow grew up round the castle which was founded here by the early English conquerors about the end of the twelfth century. It was erected into a borough by William Earl Marshal about 1208, and was surrounded with walls in 1362 by Lionel Duke of Clarence, who removed the king's exchequer hither from Dublin. Down to the revolution of 1688 the history of the castle is that of the town. It is said that the castle was seized in 1297 by Donnell Mac Art Kavanagh; and it appears to have been occasionally in the hands of the Irish till about 1494, when it was seized by a brother of the earl of Kildare, and after a siege of ten days was taken from him by the lord deputy Sir Edward Poynings. During Tyrone's rebellion Carlow castle was held by the queen's wardens; and, in the wars subsequent to the rebellion of 1641, was ineffectually besieged by the Irish (April, 1642). It was next occupied by the royalists under Captain Bellow, and on the 24th July, 1650, after a short siege, was surrendered to Sir Hardress Waller, commanding a division of Ireton's parliamentary forces. In July, 1691, the manor of Carlow was granted to Donogh O'Brien earl of Thomond, and the office of constable of the castle was bestowed on him and his son Brian in consideration of his surrender of certain castles in Tipperary and Limerick. In 1614 the castle and town of Carlow were granted to Sir Charles Wilmot, knt., at an annual rent of 6s. 8d.; and, in 1613, James I. granted a charter to the inhabitants of Carlow, constituting the town a borough, to be governed by portreeve and burgesses. This charter was confirmed by the 26th Charles II., which constitutes the borough a corporation consisting of sovereigns, burgesses, and commonalty, and is the governing charter of the town at present. The most remarkable object of antiquity in Carlow is the castle now in ruins. Its dilapidation has been comparatively recent. The whole structure, a square of 105 feet, with massive round towers at the angles, was standing in 1814, when an injudicious attempt was made to modernize it by piercing new windows and diminishing the thickness of the walls, in consequence of which more than one-half of the building fell to the ground. Its ruins, consisting of one curtain wall with its flanking towers, about 65 feet in height, stand over the left bank of the Barrow, and still form a prominent and picturesque object. Under the south side of these ruins the Burrin, a small river flowing westward from of Forth, enters the Barrow nearly at right angles.

The town consists chiefly of two main streets, one nearly parallel with the Barrow, and crossing the

Burrin by a neat metal bridge; the other at right angles leading to the suburb of Graigue, in the Queen's County, by a handsome balustraded stone bridge over the river, immediately north of the castle. Over again

the north side of the latter street, stands the parish church, a respectable edifice ornamented with a spire of great proportions, erected in 1834 at an expense of 1800

At the intersection of the main streets is the court-house, now shut up since the opening of the new court building at the entrance of the town on the northern side.

The court-house is an octagonal building of cut stone, with a handsome portico of Ionic columns, approached by a fine flight of steps, and elevated on a massive balustraded base: it forms a very ornamental termination to the main street which here diverges, the eastern branch leading to the Dublin road, the western towards the Lunatic Asylum, and villas of the gentry situated along that bank of the Barrow.

The Roman Catholic church and college stand on the eastern outskirts of the town, and are both fine buildings; the former, adorned with a lofty and highly ornamented octagonal tower, was consecrated in 1834, and cost 18,000l.; the latter, a plain but extensive edifice, was originally founded in 1789 for the education of lay and ecclesiastical Roman Catholics. A new wing was added in 1828, and the house is now calculated for 200 students. This building cost 13,000l. There is also a Roman Catholic convent here, founded 1811, with a school (now in connexion with the national board) attached, which cost 2600l. The late Dr. Doyle, Roman Catholic bishop of Kildare and Leighlin, was the chief promoter of these foundations. The county gaol, to which large additions were made in 1832, stands on the south side, and is a well-regulated establishment, where employment is provided for prisoners of both sexes. Here is a barrack for two companies of infantry and a troop of horse. The town is not lighted, and there is no public supply of water, which is procured from the rivers and by private pumps. Coal is brought from the neighbouring coal district in the Queen's County, and by the Barrow from Ross and Waterford; but the principal fuel used by the lower class is turf, which is procured from the borders of the adjoining county of Kildare. The chief manufacture carried on here is that of flour and oatmeal, large grinding mills being driven both by the Burrin and Barrow: there are two breweries and one distillery, and a considerable quantity of barley is malted in the town. The butter trade is carried on extensively, and the brand of Mr. Samuel Haughton, the chief exporter of this article from Carlow, bears the highest character among Irish butters in the English market.

In 1821 the population of that part of Carlow in the county of Carlow was 8035, and in 1831, 9114, viz. 4268 males, and 4846 females, forming 2005 families, of which 96 were chiefly engaged in agriculture, 824 in trade, manufactures and handicraft, and 1085 not included in either denomination. Houses inhabited, 1351, building, 11; unoccupied, 136, to which may be added 1600 persons and 146 houses for Graigue: 516 houses of the total number were thatched. In 1824 there were in Carlow 15 Roman Catholic and 12 Protestant schools, educating 1035 males and 662 females; and in 1834 there were on the books of the various schools 876 males and 743 females. The number of students at present in the college is 163, mostly ecclesiastical, who pay 25l. per annum each; lay students pay 34l. 2s. 6d. Of the national schools one educates 200 males, and the other 269 females, both in connexion with the Roman Catholic convent. Here is a Protestant free-school with a soup-kitchen for the poor attached; the number of pupils is from 200 to 250. Under the same roof are the apartments of an industrious association for bettering the condition of the female peasantry, of a Protestant orphan society, and of a Protestant benevolent society for clothing.

The lunatic asylum for the counties of Carlow, Kildare, Wexford, Kilkenny, and Kilkenny city, which is half a mile north of the town, was opened in 1831; it cost 22,532l. 10s. 4d., is calculated to accommodate 106 patients, and is supported at an expense of about 2000l. per annum. In 1833 there were 46 patients, and in 1836, 122.

Carlow is a neat and thriving town, situated in a rich country, and is the residence of many respectable individuals. (Ryan's History of the County of Carlow, Parliamentary Reports and Papers, Original Communications.)

CARLSBAD, a royal town, celebrated for its mineral waters, and built on both banks of the Elbe, is in the circle

of Eger in its celebrity appears to have been well known even in the seventh century, by the name of Teplowody, for the Bohemians of that day constructed altars to their divinities out of the stones over which the spring made its way. It did not attract much attention until the year 1370, when Charles IV. and his attendants, as the tradition says, while following the chase in its vicinity, having hunted a stag to the edge of a precipice, drove the animal down it; one of the hounds that leapt after the prey finding himself immersed in a concealed spring instead of alighting on firm ground, set up so pitiful a howl that some of the huntsmen came to his assistance. Charles's body-physician, Beier, was one of the party, and formed so high an opinion of the virtues of the water, that he recommended his royal master to use it for the cure of some ailment under which he laboured. The result having established its efficacy, Charles founded a free town on the spot, settled the inhabitants of a neighbouring village upon it, ordered baths to be opened, and gave his own name to them.

Carlsbad is in a deep narrow valley, and contains about 500 houses; the resident inhabitants are nearly 3000 in number. The valley is traversed by the Tepl, which falls into the Eger just below the town, and is bounded on every side by lofty heights of granite. The houses branch out into three distinct ravines or lesser valleys, which are under the brow of the Hummerberg, Kreuzberg, and Lorenzberg. A more delightful scene cannot be conceived than the prospects from the summit of these heights, particularly the Kreuzberg. The hot springs, which are close to the banks of the Tepl, consist of the Sprudel, near which are some salt-works; the Hygieia Well; the Schloss-Spring, which disappeared in 1809 and returned in 1823; and the New, Mill, Bernhard, Theresia, and Spital Wells. They emit a delicate vapour, which constantly hangs over the town, and has a peculiar odour. The whole of the springs have been estimated to yield about 128,212 cimer (1,923,180 gallons) in the 24 hours, of which 1,669,300 flow from the Sprudel and Hygieia springs alone. There are vapour and other baths. The Wiesen street, a small row of houses, lines the banks of the Tepl; and on a line with it are two sets of assembly rooms, as well as the Puppische Allée, a promenade of lime and chestnut trees, under which stands are erected for the sale of millinery, fancy articles, &c. The church, townhall, theatre, assembly rooms, hospital, and market-place are the chief buildings. On the left bank of the Tepl are what are called the Old and New Meadows, forming a handsome terrace, lined with well-built houses, ornamented with a theatre, and planted with trees. The vicinity of Carlsbad abounds in pleasant walks and drives. The visitors have increased from 256 to upwards of 2000, on the average, annually since the year 1764; in some seasons there have been 4000. An hospital, into which about 130 strangers are yearly admitted, was founded here in 1812. There are manufactories of needles, cutlery, hardware, arms, &c. 50° 13' N. lat., 12° 52' E. long.

CARLSKRONA, a town in Sweden, in the province of Blekinge or Carlskrona Län, 56° 10' N. lat., and 15° 30' E. long. It is built on a small island and a few adjacent rocks, and united to the main land by a long bridge, which unites three rocks, lying one behind the other, between the town and the continent, and may therefore be considered as one very long bridge. Its streets are wide and straight, but the ground on which the town stands is uneven. The houses are commonly good, though small; many of them are built of stone and the rest of wood.

This town is the station of the Swedish navy. The harbour, formed by a series of islands lying about three miles distant from the continent, is spacious, safe, and convenient, and has depth enough for the largest men-of-war. There are three entrances. The principal entrance opens to the S. opposite the town, between the islands Aspö and Tjurkö, on which strong fortifications have been erected to defend the port. This is the only entrance that is practicable for the larger vessels. The entrance to the W. of it is called Aspöund, and may be entered by frigates, and still smaller vessels and admiralships into the harbour by the E. entrance, called Skarvöund.

The dry docks of this harbour have always attracted the attention of foreigners. The old dock, built in the beginning of the last century, is cut in a hard rock, and is 200 feet long by 50 feet wide. It is deep enough for the largest

vessels. The new dock is much more extensive, and consists of several divisions for the building of different kinds of vessels; it is likewise cut in hard rock, and was made towards the end of the last century. The other buildings are the arsenal, the artillery-yard, and the admiralty. The greatest inconvenience to which the inhabitants are exposed is the want of good water; that which is drawn from the wells in the town is brackish, and the poorer classes, who use it, are subject to putrid fevers in summer; good water is brought from a distance of more than four miles. Carlskrona is the seat of the governor of the province, and contains about 12,500 inhabitants: its commerce is unimportant. (Schubert's *Travels*.)

CARLSRUHE, the capital of the grand duchy of Baden and residence of the grand duke, is in the circle of the Middle Rhine, and lies about four miles E. of the Rhine and about 13 from the edge of the Black Forest. It stands at an elevation of 372 feet above the level of the sea and 50 feet above that of the Rhine. Its origin was a hunting-seat built on the spot by Charles William, Margrave of Baden, 118 years ago. It is constructed in the form of an extended fan, the present palace constituting the central point, from which 32 avenues diverge: hitherto 11 only of these avenues have been lined with rows of houses, which form the main streets of which the town at present consists. Some of them are spread into the beautiful forest of Hart, which is situated to the N. and W. of Carlsruhe; on the other side, gardens, fields, and meadows encircle the town. The streets commence from a semicircular row of hand-some houses with arcades to them, which fronts the palace and is called the Great Circle. The whole area which the town occupies is 300 acres. One side is open, another walled in, and a third palisaded; it is entered by seven gates: the entire number of streets is 33; they are broad, and furnished with foot-pavements. The long street, which runs from E. to W., and the palace street, which traverses from N. to S., divide Carlsruhe into four districts. What is denominated the Lenden Tower (Bleithurm) stands in the centre of the palace, and is in fact the centre of the whole elevation on which the town is built; the right wing of this edifice contains the public library (about 70,000 volumes), a collection of antiques and coins, &c.; and the left wing, the church of the court. The open space in front is ornamented with quadruple rows of trees on each side, disposed in two oblong squares, with basins of water in the middle. The great circle contains the government offices, as well as the spacious palace of Margrave Maximilian.

Carlsruhe has nine public squares, the finest of which is the market-place, in length 180 feet and in breadth varying from 50 to 70; it is skirted by handsome houses, four stories high, which rest on arcades. A stone pyramid, with an inscription in memory of Charles William, the founder of the place, whose remains are inclosed in it, stands in the centre of the square. The style of the houses is various; some are in the Dutch, others in the French, and many in a mixed Greek and Roman, which last is that now in vogue. Opposite the palace stand the government buildings, connected by an arcade; on one side of them are the orangery and offices for the grand ducal gardens, and on the other the riding-school and grand ducal stables and offices. The churches consist of the new Protestant church, a very handsome edifice, commenced in 1807, and decorated with a fine altar-piece of the Ascension and painted sides to the galleries—beneath the church is a long range of vaults for the interment of the grand ducal family; the new Catholic church, a modern structure also, built in the shape of a cross, with an elegant tower and portico; and lastly the garrison church, in the French style of the last century: a very handsome synagogue in the Eastern style has also been erected. The town-hall was commenced in 1821, in which year also the building for the legislative assembly was finished; it is three stories high and contains two fine halls for the sittings of the two chambers, besides residences for the president, officers, &c., and depositories for the archives and papers. There are also the palaces of the Margraves Amalia and Frederica, and of the Prince of Fürstenberg and Count Bismark; the museum; the mint and offices of works; the academy of the arts and sciences with a picture-gallery attached to it; the arsenal, foundry for cannon, military teachers' and polytechnic schools, lyceum, post-office, and barracks. Altogether Carlsruhe contains above 1200 buildings, of which 90 are public, independently of 14 palaces and 1100 private dwellings. It

possesses a botanical garden, a veterinary school, four hospitals, a deaf and dumb asylum, a bible-society, an association for promoting national industry, a Jewish society for encouraging agricultural pursuits among the Jews, and other useful and benevolent institutions.

The population of Carlsruhe is greatly on the increase. It consisted of 16,789 souls in the year 1816, and at present exceeds 20,000, inclusive of the military and strangers. In 1828 their numbers were 19,718, of whom 12,906 were Protestants, 5803 Roman Catholics, and 1009 Jews. At this time the males amounted to 10,135 and the females to 9583. The inhabitants derive their livelihood principally from trade, mechanical employments, and manufactures, and the natural expenditure arising from Carlsruhe being the seat of government for the grand duchy. The cultivation of grain, fruit, vegetables, and hemp, is a secondary means of subsistence. In 1833 there were upwards of 1000 persons employed as mechanics and in connexion with trade, besides 2000 labourers, &c. The chief manufactures are silks, cottons, carpets, woollens, jewellery, tobacco, leather, and articles of luxury. The consumption of animal food in 1836, when the population was below 19,000, amounted to 2304 bullocks, 718 cows, 1740 heifers, 10,524 calves, 1573 sheep, 5730 swine, and 22 goats.

In and about the town there is a variety of public and private gardens and grounds open for the amusement of visitors, particularly the Palace Gardens, containing 70 acres, the Pleasants' Garden, 360 acres in extent, the Botanical Garden, which is the third as to value in Germany, &c.; collections in the arts and sciences are also numerous. The English plantation (*Englische Anlage*) leads to the baths of Beierthorn, beyond which is the hunting-seat of Scheidenhard; and there are a number of attractive spots in other directions. Carlsruhe is in 48° 56' N. lat., and 8° 22' E. long.

CARLSTADT, (in Hungarian Latin, *Carolostadium*, and in Slavonian, *Karlovecz*.) the capital of the circle, called the *Carlstädter-kreis*, in the southern part of the Austrian province of Agram in Hungary. It stands at an elevation of about 894 feet above the sea, in a picturesque situation on the banks of the Kulpn, and at the confluence of that river with the Korana and Mresnicza. It has long been a royal free town, and has a fortress, constructed by the archduke Charles of Styria, in 1579, though in the present day it is less important in a military than in a commercial point of view. The town is not ill-built, although the houses are mostly of wood; it consists of the inner town, the fortress, and Dobovacz, a suburb. The fortress, originally designed as a bulwark against the inroads of the Turks, is encompassed by ramparts, a ditch, and palisades, and though on a small scale, has a handsome parade, on which there are barracks and an arsenal. Besides 5 Roman Catholic, a Greek church, and a Franciscan monastery, the oriental Christians, about 170 individuals in number, possess a place of worship here. It is the residence also of a Greek bishop; and has a gymnasium, conducted by Franciscans, and a head school, as well as one for females. The population, including the suburb and fortress, is about 6300; at the close of 1804 it did not exceed 4200. There are few mechanics or manufacturers in the place. It has a distillery, builds small craft, and carries on an extensive transit-trade between the ports on the Adriatic and Lower Hungary and Slavonia. It is in 45° 29' N. lat., 15° 37' E. long.

CARMAGNOLA, FRANCESCO BUSSONE DI, Count of Castelnovo, was born at Carmagnola, a town of the province of Turin in Piedmont, about the year 1390, of humble parents. Early in life he enlisted into the troop of Facino Cane, a celebrated Condottiere of his time, who was in the service of the Visconti, Dukes of Milan. As he rose in rank he took the name of Carmagnola, from the place of his birth. After the death of Facino, Filippo Maria Visconti made Carmagnola his general in chief, as a reward for his bravery and services. Carmagnola was chiefly instrumental in placing Filippo Maria on the ducal throne of Milan, and he afterwards added to his dominions Piacenza, Brescia, Bergamo, and other towns. Filippo Maria created him Count of Castelnovo, gave him in marriage his relative Autometta Visconti, and sent him out as governor. In 1424 Filippo Maria, who was of a suspicious temper, having listened to the favourable reports of some counsellors around him, ordered Carmagnola to be deprived of his military command, upon

which the latter repaired to the duke to remonstrate; but being denied an audience, he rode off with a trusty companions, left the territory of Milan, and after some wanderings repaired to Treviso, in the Venetian territory, where the duke sent an assassin to murder him, but the plot failed. He then went to Venice, where he arrived in February, 1425.

The Venetian senate having declared war against the duke, in January, 1426, appointed Carmagnola their captain-general. Carmagnola defeated the duke's troops and took from him the province of Brescia, which was from that time incorporated with the Venetian state. In 1427 he defeated again, near Macoldio, the duke's troops, which were led by Sforza, Pergola, Piccinino, and Torella, all celebrated Condottieri of that time. After the battle, Carmagnola's soldiers, who were chiefly mercenaries, liberated all their prisoners, according to the custom then prevalent among the Italian Condottieri; the reason of which was, that as those troops fought merely for pay, they did not wish utterly to destroy their antagonists, for fear that the war should come to an end too soon. The Venetian commissaries, who accompanied the army, remonstrated with Carmagnola upon this occasion, but that chief asserted the usage and privilege of his soldiers.

In 1428 peace was made between Venice and the duke, but in 1431 war broke out again, and Carmagnola, retaining the command of the Venetian army, attacked the castle of Soncino, but failed after a considerable loss. Shortly after, in July of the same year, the duke's flotilla on the Po defeated that of Venice, in sight of Carmagnola's camp, who was not in time to support it. That commander was accused of neglect and even suspected of treachery. The senate wrote him a letter of reproof, but continued him in command. In the following October Carmagnola attempted to surprise Cremona; part of his men entered the town, but the citizens rising in a mass, drove out the assailants. This failure increased the suspicions and fears of the Venetian senators, who determined to deprive Carmagnola of his command, but fearing to attempt it while he was in the midst of his soldiers, by whom he was beloved, they invited him by courteous letters to repair to Venice in order that they might consult with him on the peace to be made with the duke. Carmagnola went to Venice, where he was received with marked distinction, and was led immediately to the ducal palace. Being introduced into the hall of the Council of Ten, he was all at once charged with treason, arrested, taken to the adjoining prison, examined secretly, put to the torture, and condemned to death. On the 5th May, 1432, he was led out, with his mouth gagged, to the Piazzetta of St. Mark, and there beheaded between the two pillars. His property was confiscated to the state. Concerning the guilt or innocence of this celebrated commander much diversity of opinion prevails. Manzoni, a living Italian writer, in his '*Notizie Storiche*,' which accompany his drama '*Il Conte di Carmagnola*,' has fully examined the question and referred to the authorities on both sides.

CARMEI, MOUNT. In its most restricted sense this name is applied to a mountain about 1500 feet high, forming the southern promontory or cape of the Bay of Acre. More largely, it is applied to the chain of hills to which that mountain belongs, and the extent of which is variously stated at from six or eight to twelve or fourteen miles. This uncertainty seems to proceed from the range having no very marked termination, the whole being, in fact, merely the terminating portion of the large range which extends about a hundred miles from Point Carmel, southward, to below Hebron, in its course intersecting the country about midway between the Jordan and the sea. Carmel seems to be sometimes understood in this large sense in Scripture, as we find the name applied to mountains within the territory of Judah, the most southern tribe. (Josh. xv. 55; 1 Sam. xxv. 2; and 2 Sam. iii. 3.) The north-western portion of this range, to which the name of Mount Carmel is more usually given, slopes down to the sea on one side, and to the Bay of Acre on the other; but in its extension south-eastward, a small plain intervenes between it and the sea on the west; while the river Kishon winds along its eastern base, beyond which opens the great plain of Esdraelon. The mountain is described as rocky, composed of a whitish stone, in which flints are embedded. On the summit of this short range, oaks, pines, and other trees grow; and the vines and olive trees which are still seen among the

brambles indicate that its surface was once under cultivation. The sides are still covered with rich pastures, where shepherds feed their flocks as they did when the Hebrew prophets described it as the 'habitation' of shepherds.

Carmel contains numerous caves, particularly on the western side. The largest of these, according to tradition, was occupied by the prophet Elijah, the most remarkable events of whose history are connected with Mount Carmel. On the summit there is a monastery belonging to the Carmelite monks, who took their denomination from this mountain. The site of the monastery is believed to be the spot on which Elijah offered sacrifice. It was never a fine building, and although in tolerable repair has been deserted for many years, the single monk who has the care of it residing in the town of Caïpha at the foot of the mountain.

CARMINATIVES, agents chiefly obtained from the vegetable kingdom, are employed to promote the expulsion of flatulence. Though gases of different kinds are occasionally secreted by the inner surface of several organs of the body, those gases which infest the intestinal canal are in a great measure the result of the fermentation of articles of food, the digestion of which is slow or imperfect. Whatever causes indigestion favours the formation of such gases; hence they mostly trouble infants, whose stomachs are generally feeble, or hypochondriacal and hysterical individuals, or those who lead a sedentary life. Substances which impart, even for a very short time, that energy and power which, in such persons, the stomach and intestines appear to be destitute of, enable them to throw off the wind which oppresses these organs. Plants possessed of an aromatic principle, owing to the presence of a volatile oil, are employed to effect this end, which they sometimes accomplish even when applied to the external surface of the stomach, and much more certainly when taken internally. Instead of the plants in a raw or dried state, the oil is often extracted from them by distillation, or a tincture or even a distilled water is formed from them, and administered under similar circumstances; and this last mode is in general the best. A few drops of the oil, or of the tincture of any of these plants, may be dropped upon sugar, and so introduced into the stomach, or the distilled water may be made the vehicle for the administration of other medicines proper to be given at the same time. Thus some alkaline earth, such as magnesia or its carbonate, or a pure alkali, such as liquor potassæ, or an alkaline carbonate, may be given at the same time with good effect.

As a general rule, it may be stated that if these stimulants fail on their first exhibition to give the relief expected, they should not be repeated without the sanction and advice of a competent medical attendant; for, even if an inflammatory condition of the stomach and intestines do not already exist, the continuance of colicky pains is apt to produce it; especially if assisted by brandy or other stimulants. Even dill or anise may affect too powerfully the sensitive nervous system of infants, for these are by no means such simple agents as is commonly supposed: the seeds of dill poison bullfinches, canary birds are killed by those of anise, and parrots by those of parsley.

The safest and most effectual means of avoiding the distressing symptoms attendant on the disengagement of flatus are great attention to diet and regimen. Regular exercise should be taken daily. The food should be plain; soups and much liquid, particularly tea, should be avoided; and the person should retire to rest at an early hour. [**AROMATICS, ANTISPASMODICS.**]

CARMINE, one of the most beautiful of the red colours used by painters. It is obtained from cochineal by the following process:—Boil 12 lbs. of filtered rain-water in a tin vessel, and add to it 4 ounces of finely-powdered cochineal; boil for five minutes, constantly stirring with a glass rod; then add 5 scruples of alum in fine powder, and perfectly free from iron; boil again for two minutes, remove the vessel from the fire, cover it, and allow the contents to settle. As soon as the liquor is clear, pour it while still hot into glass or porcelain vessels, and suffer it to remain for some days, covered from the dust. The alum gradually precipitates the colouring matter, in combination with animal matter and a little alumina; this last however is not essential to the colour. The precipitate is put on a filter, washed, and dried in the shade.

These directions are taken from Berzelius's 'Traté de

Chimie,' t. vii, p. 676. He states also that some other kinds of carmine are prepared from cochineal.

The colouring matter of carmine may be extracted by ammonia, and the best is almost entirely soluble in this alkali, leaving only a little alumina; this colouring matter has been called *carmin*, for an account of which, and some other properties of cochineal, see **COCHINEAL**.

CARNAC, a village or small town in France, in the department of Morbihan, not far from Auray, remarkable only for the remains of an extensive Celtic monument, of which we subjoin a description from Mrs. Stothard's *Letters written during a Tour in Normandy and Brittany*, London, 1820, 4to., p. 256 et seq. :—

'We hired a cabriolet, and left Auray early this morning; besides the driver, a man accompanied us, who walked by the side of the voiture, in order to render his assistance in preventing it from being upset by the large, loose, and broken rocks that strewed the way, and lie in confused heaps about the road. After travelling three leagues through a desolate and wild country, we arrived at a spot about a mile from the sea-shore, where this curious Celtic antiquity remains, a monument at once of the power and insufficiency of man, for his own stupendous work has long outlived all memory of its founder or its history. Carnac is infinitely more extensive than Stonehenge, but of ruder formation; the stones are much broken, fallen down, and displaced; they consist of eleven rows of unwrought pieces of rock or stone, merely set up on end in the earth, without any pieces crossing them at top. These stones are of great thickness, but not exceeding nine or twelve feet in height; there may be some few fifteen feet. The rows are placed from fifteen to eighteen paces from each other, extending in length (taking rather a semicircular direction) above half a mile, on unequal ground, and towards one end upon a hilly site. The semicircular direction was probably accidental, as from their situation it was not possible to see all the ground at once, in order to range them in a straight line. When the length of these rows is considered, there must have been nearly 300 stones in each, and there are eleven rows; this will give you some idea of the immensity of the work, and the labour such a construction required. It is said that there are above 4000 stones now remaining. We remarked three tumuli, probably the graves of chiefs; they are formed of large stones placed upon each other, on a raised bed of earth. In some places the irregular line of the work is broken by the ground having been cleared for fields; in others, the stones that have fallen were broken up and carried away for building. More injury has perhaps been done to this stupendous Celtic work by the hand of man than by that of time. The place was peculiarly well chosen for obtaining materials to construct such a monument, as the ground for miles round is full of rock. We could gain no information from the people relative to anything that might have been found; for in answer to whatever we said to the peasantry, we received replies in the Breton tongue, of which we could only articulate distinctly the word *Gaelic*, and this was repeated whenever we accosted them. I have been informed by a priest, but I know not how far it may be correct, that *Carnac* signifies literally, in the Breton language, a *field of flesh*.* If this be the meaning of the word, it would lend one to conjecture that these stones were placed in memory of some great battle, or as memorials in a common cemetery of the dead. The people have a singular custom, whenever any of their cattle are diseased, of coming among these stones to pray to St. Cornelius for their recovery. Such a practice may be a remnant of pagan superstition continued in Christian times; but I must remark that St. Cornelius is the patron saint of the neighbouring church. I cannot learn that the peasantry of this country have any traditions about Carnac; and I must here observe that no relations or accounts given either by the poor or more enlightened people of Brittany can be depended upon.

M. Cambry, in his *Monuments Celtiques*, has given the stones, which he professes to have measured, much greater dimensions than those assigned to them by Mrs. Stothard, who unhesitatingly charges him with exaggeration. I have measured, says M. C., 'the principal stones of Carnac; the tallest are twenty-one to twenty-two (French) feet above the ground; their breadth and thickness vary, as does

* Du Centre, as quoted by Ogée, gives, as the translation of Carnac, a buried place or cemetery.

The French foot is to the English foot as 12 to 13, and the French inch is to the English inch as 12 to 13.

their height; but some of them are enormous, as in the part near Kervario, near the mill of Kerner. One of them is twenty-two feet in height, twelve in breadth, and six in thickness, without including the part buried in the sand. It ought to weigh, supposing the cubic foot of granite to be 200 (French) lbs., 256,800 lbs. Ogée, in his *Dictionnaire de Bretagne*, gives dimensions nearly equal to those of M. Cambry, with whom he also agrees in the statement that the stones are placed on the smaller end, and that some appear to be balanced as it were on a pivot, like the 'rocking stones' of our own island. He further supposes, from the nature of the soil, that the stones were quarried on the very spot, and M. Cambry thinks they might have been procured from some quarries a league towards the east; but M. Daru (*Histoire de Bretagne*) describes the monument as being far from all known quarries.

The origin of this singular memorial is quite unknown; the conjectures of Mrs. Stothard have been given. Ogée supposes these stones to be the remains of a camp formed by Julius Cæsar, in his war with the Veneti, or people of Vannes; but the nature of the monument puts this supposition out of the question—a Roman origin cannot reasonably be assigned to the monument. Tradition has given to the site of these stones the name of Cæsar's Camp, but tradition in such a question is an insufficient guide. M. Cambry, led by another tradition, reported to him by an old sailor, that a stone was added every year, conjectures, though with hesitation, that the monument has some connexion with the astronomy of a remote age.

CARNAR. [THEBES.]

CARNATIC, a province in the south of Hindustan, extending from 8° to 16° N. lat., and included between 77° and 81° E. long. This province comprehends the former dominions of the Nabobs of Arcot, stretching from Cape Comorin on the S. to the small river Gundigama, by which it is separated from the Circars on the N. On the E. it is bounded by the Bay of Bengal, having a line of coast 560 miles long; and on the W. are Coimbatore, the Barramahall districts, and districts ceded by the Nizam. The breadth of the province is no where greater than 110 miles, and the average breadth is about 75 miles: it is narrowest towards the N. The chain of hills, known as the Eastern Ghauts, commences in the S., about 11° 20' N. lat., and extend northward in a direct line to 16° N. lat., separating the Carnatic throughout their extent into two divisions, one called Carnatic Balaghaunt, or above the Ghauts [BALAGHAUNT]; the other the Carnatic Paycenghaunt, or below the Ghauts. The province is further divided in its length into three parts, severally called the Southern, the Central, and the Northern Carnatic. The first of these divisions is S. of the river Coleroon, the northern branch of the Cavery, which runs from Trichinopoly to the Bay of Bengal. This part of the Carnatic did not form an integral part of the dominions of the Nabob of Arcot, but was tributary to that chief. The principal towns which it contains are Tanjore, Trichinopoly, Madurai, Tranquebar, Negapatam, Tinnevely, and Nagore.

The Central Carnatic has the Coleroon for its southern, and the Penaur for its northern boundary. Its chief towns are Madra, Pondicherry, Arcot, Wallajahad, Vellore, Conjeveram, Chingleput, Ginjee, Pullicat, Chandgerry, and Nellore.

The Northern Carnatic comprehends the remainder of the province, and is included between the Penaur on the S. and the Gundigama on the N.: the chief towns are Angole, Carwarce, and Saumgaum.

Wallajahad is 14 miles N.W. from the town of Chingleput, in 12° 48' N. lat., and 79° 53' E. long. The town contains extensive military cantonments. Ginjee was formerly considered by the natives to be the strongest fortress in the Carnatic. The works cover the summits and great part of the sides of these detached rocky mountains, upwards of 500 feet high, and difficult of access: the whole are connected by means of lines which inclose the plain between the mountains, and contain within them a fortified barrier, dividing the works into an outer and an inner fort. This fortress was built about the middle of the 16th century, and was successively strengthened by its Mohammedan and Mahratta possessors. It surrendered to the British in 1781, and has since been so completely neglected that in 1829 it did not contain a single inhabitant, while the pottah, the town or suburb, was reduced to about 34 houses. The walls, gates, and bastions were at that time still entire, as well as a part of the seven storied tower of

the rock, Angole, and Angole. Angole is situated in 12° 12' N. lat., and 79° 28' E. long, 33 miles N.W. from Pondicherry. The town of Pullicat stands on a lake separated from the sea by a low sandy beach, in 12° 25' N. lat., and 80° 24' E. long., 23 miles N. from Madras. The Dutch formed a settlement here as early as 1682, and after the loss of Negapatam, made it their chief station on the Comandel coast. Saumgaum is situated in 14° 25' N. lat., and 79° 47' E. long., 17 miles N.W. from Nellore.

The climate of the Carnatic Paycenghaunt, which has the sea on one side and an abrupt mountain ridge on the other, is considered to be the hottest in India. Immediately upon the coast the heat is somewhat mitigated by the sea breeze, but 10 or 12 miles inland this breeze does not reach until the evening, and has then lost its cooling property by passing over the intervening country. The failure of this sea breeze, which sometimes occurs for several successive days, occasions a degree of heat most distressing to the inhabitants, the thermometer rising to 130° in the shade. From May to July, occasional showers occur, and sometimes it rains heavily and continuously for three or four days, by which the air is cooled and vegetation assisted.

The soil of the province near the coast is a mixture of sand and loam, sparingly intermixed with the remains of marine animals, and bearing evident marks of having been once covered by the sea. The sand of this coast is formed of the debris of the mountains washed down by the periodical torrents. The proportion of felspar brought down with the sand is unfavourable to the fertility of the soil. In many parts the soil is strongly impregnated with iron, and in other parts there is a considerable efflorescence of common salt upon the surface in dry weather. The saline substance does not generally extend far inland; but here and there spots of salt ground are met with, and occasionally also a mixture of salt and soda, which, from the use to which it is applied is known in the country as *washermen's earth*. In the valleys along the ghauts, and between the ranges of hills, the soil is chiefly loam and sand, with a considerable proportion of vegetable mould. In these valleys, and especially where they are watered by rivers and tanks, the soil is tolerably fertile; the high grounds are always poor, because of the gradual washing away of the soil which has been deposited in the valleys.

The principal rivers of the province are the Penaur, the Palaur, the Coleroon, and the Vaygaroo. The whole of these have their sources in the table-land above the ghauts, and discharge themselves into the Bay of Bengal. The Penaur rises in Mysore, near the fortress of Nundydroog, and taking a south-easterly direction, falls into the sea at Cudalore, after a course, including its windings, of about 250 miles. The source of the Palaur is very near that of the Penaur: it has a winding course towards the north-east of about 220 miles, and falls into the sea near Sadras, in 12° 31' N. lat., and 80° 14' E. long. The Coleroon, as already mentioned, is a branch of the Cavery. The Vaygaroo rises in the high lands to the south of Mysore, flows with a tolerably direct course south-east past Madurai, and falls into the sea about twenty miles south of Tondi, in 12° 25' N. lat., and 79° 5' E. long. During its course the waters of this river are much employed for irrigation, and near its mouth there is a large tank, by which it is in great part absorbed: its channel is partially dry during part of the year.

The low lands are chiefly devoted to the cultivation of rice, and their rent depends upon the facility with which they can be irrigated. There are four different harvests in the year, two of which are raised upon the same ground. For the first harvest the seed is sown in May, and ripens in September; for the second the seed is sown in June and July, and the grain is cut in October or November; the third seed-time is in September, and its harvest in January or February; and the fourth crop, which is sown between November and January, ripens in April and May. The increase in ordinary seasons is expected to be for the first crop fifty-fold, for the second and third each forty-fold, and for the last from twenty to thirty-fold of the seed; the proportion sown being about ten bushels to the English acre.

The high grounds which cannot be watered are principally employed for raising different quantities of millet, and a few leguminous plants. Sugar is cultivated only in small quantities, owing to the poverty of the soil. Indigo answers better, and cotton, in some situations, grows luxuriantly: the variety cultivated is the *Gossypium arboreum*. The great bulk of the productions of the Carnatic are

Hindus, the professors of Mohammedanism being very thinly scattered over the country. A great part of the land is cultivated by Bahminas, who do not engage personally in the task of cultivation, but employ labourers of the inferior castes. There are a few Mohammedan farmers whose land is tilled by slaves, but the most numerous class of cultivators are Sudras, many of whom perform all the operations of the farm with their own hands.

The first invasion of the Carnatic on the part of the Mohammedans was in the year 1310, when the Hindu sovereignty was made tributary to the Mogul emperor. It does not appear that the conquest of the country was consummated until 1717, in which year Nizam ul Mulk obtained independent possession of the south of India, and the dependence of the Carnatic upon the throne of Delhi ceased. In 1743 Unwer-ud-Deen received from Nizam ul Mulk the appointment of nabob of the Carnatic and of its capital, Arcot. On the death of the nabob in 1749, the succession was disputed by Chunda Saheb and Mohammed Ali, more commonly called Walla-jah. The French took the part of the former, while the latter was supported by the English, and through their exertions was established as nabob of the Carnatic, his right to which office was recognised by the French in the Treaty of Paris, 1763, and the Treaty of Versailles, 1783. Walla-jah, who aspired to the sonbahdarry of the Deccan, would gladly have cast off his dependence upon the English, but was retained by them as a subsidiary ally until his death, which occurred in 1795, when he was succeeded by his son Omdut-ul-Omra. Previously to this event, in 1790, the nabob having failed to make payment to the East India Company of the amount of his subsidy, which had been fixed at nine lacs of pagodas per annum (360,000*l.*), Lord Cornwallis assumed the management of the revenues, and employed the Company's servants for their collection. This course was abandoned in 1792, when the nabob came anew under engagements for payment of the same amount of subsidy, certain districts being rendered liable to be entered upon in case of failure in payment, and in the event of war with Mysore, the whole territory was to be assumed by the Company, a suitable sum being reserved for the maintenance of the nabob.

In 1801 the civil and military government of the Carnatic was transferred to the East India Company by the nabob Uzeem-ud-Dowlah, upon the Company engaging to pay him annually one-fifth of the net revenue of the country, and providing for the principal officers of his government. [Archer.]

In every part of the province there were formerly numerous fortresses. Wherever a position was naturally favourable for defence, works were erected. Major Rennell, speaking of this part of India, says, 'The almost incredible number of forts and fortresses of various kinds in the Carnatic occupies a greater number of interesting positions within the same space, than in most other countries. Villages, and even towns, in open countries, are but of a day, compared with fortresses, especially when they derive any portion of strength from their situation, a very common case here.' Since the time when this was written, the province has enjoyed a long continuance of tranquillity; the forts have many of them crumbled to pieces, and those still visible are fast falling to decay, while the towns and villages have multiplied in number and increased in extent.

[Rennell's *Memoir of a Map of Hindustan*; Heyne's *Historical and Statistical Tracts on India*; Mill's *History of British India*; Reports of Committees of House of Commons on the Affairs of India.]

CARNATION, a kind of dianthus or pink, a variety of the *Dianthus Caryophyllus* of botanists, much esteemed by florists for the beautiful colours of its sweet scented double flowers. It is usually grown in rich light loamy soil, in which sand enough is mixed to prevent water stagnating, and is propagated by either cuttings or layering. A great many varieties are cultivated, the most esteemed of which are those with a strong tall stem about three feet high, and regularly formed flowers with the stripes or markings clear, well defined, and broadest near the end of the petals. From their colours they are technically distinguished into *Moires*, which have but one colour, disposed in stripes upon a white ground; *Bicolors*, which have stripes of two colours; and *Variegates* or *Reparties*, which have petals notched at the edges, and spotted instead of striped upon a ground that is most commonly pale yellow.

Success in the management of these beautiful plants de-

pends very much upon attention to a great number of minute details, that would be out of their place in a work like this, and upon practical experience. Good information upon the subject will be found in Madduck's *Florists' Directory*, and Hogg's *Treatise upon the Culture of Florists' Flowers*, with its Supplement.

CARNEADES, a native of Cyrene in Africa, was the founder of the school of philosophy called the New Academy. The precise date of his birth is difficult to ascertain; it was probably about B.C. 214. He appears to have received his first instruction in philosophy from Diogenes the Stoic, and hence the joke recorded by Cicero (*Acad. Quest.* iv. 30): he sometimes said, 'If I have argued correctly, I am satisfied; if badly, Diogenes shall give back his mina.' He afterwards attended the lectures of Egesinus, master of the academy, and succeeded him in the chair. In this situation he attained great eminence, and so high was the estimation in which he was held that (Cic. *De Orat.* ii. 37; Aul. Gell. vii. 14) he was selected with two others, Diogenes the Stoic, and Critolaus the Peripatetic, to go on an embassy from Athens to Rome (B.C. 154). Cicero (*De Fin.* iii. 12) praises him for his great eloquence, which Anulus Gallius (vii. 14) describes as vehement and rapid, differing in this respect from the correct and elegant style of Diogenes and the quiet and chaste style of Critolaus. Cicero (*De Orat.* ii. 38) says that he never defended a point which he did not prove, or opposed an argument which he did not overthrow. Even other philosophers and orators, it is said, constantly resorted to his school. (Diog. Laert. *Life of Carn.*) Carneades not unfrequently sacrificed personal comfort and cleanliness to ardour in his favourite pursuits; he sometimes forgot to take his meals, and often grugged the time necessary for combing his hair, &c. Before disputing, as he frequently did, with Chrysippus the Stoic, he was accustomed to brace the powers of his mind by the exhibition of hellebore. (Valer. Max. viii. 7.) He died at the age of ninety, according to Cicero (*Acad. Quest.* iv. 6) and Valerius Maximus (viii. 7).

The doctrines of Carneades appear to have differed little from those of Arcesilaus and the other philosophers of the Middle Academy. The difference consisted more perhaps in the mode of statement than in the tenets themselves. Clitomachus, who succeeded Carneades, owned that he was never able to ascertain what the precise doctrines of his predecessor were. Carneades maintained that as the senses and understanding frequently deceive us, nothing which we learn by means of them can be certain; that the highest point we can attain is great probability, and that of probability there are several degrees. He considered that all the knowledge which the human mind was capable of gaining ought not to be called knowledge but opinion, as there was no sure test of truth. Arcesilaus appears to have maintained the same tenets, but to have asserted them in a broader and more offensive manner. He was chiefly employed in destroying the systems of others by means of his doctrine of uncertainty, and he almost entirely disregarded the application of his principles in the form of ethics; while Carneades, on the other hand, devoted himself partly to their practical use in the affairs of life. The constructive method of Carneades preserved him from the odium and suspicion which the destructive and aggressive method had brought upon Arcesilaus. [ARCESILAUS.]

CARNEGIE, SIR ROBERT, of Kinnaird, son of John de Carnegie, who was killed at the battle of Flodden, was sometime chamberlain of Arbroath, and having attached himself to the regent Arran, was, on 4th July, 1547, appointed a lord of session, but under proviso that, until an actual vacancy should occur, he should draw no salary or emolument from the place. The following year he was sent to England to treat for the ransom of the earl of Huntly, chancellor of Scotland, who had been taken prisoner at the battle of Pinkie. He was soon afterwards despatched on a mission to the court of France; and when there was requested by king Henry II. to use his influence with Arran for the resignation of the regency in favour of the queen dowager, which was effected. In 1551 we find him clerk to the treasurer of Scotland, and one of the commissioners named to conclude a peace with England; and in 1554 and 1555 he was again employed in a like capacity. At the breaking out of the Reformation he at first took part with the queen regent, and was employed by her in negotiating with the lords of the congregation; but afterwards he joined the latter, and was despatched by them to

the courts of England and France to explain their intentions. He died on the 5th July, 1866; and in the queen's letter nominating his successor on the bench, he is described as a person 'well inclined to justice, and expert in matters concerning the common weill of this realm.' He was in all likelihood the author of the work on Scots law, which is cited in Balfour's 'Practicks' by the quaint title of *Lib. Carnegie*, or Carnegie's book.

CARNELIAN. [*AGATE.*]

CARNIOLA (KRAIN), a former duchy of Austria, now forms three of the five circles into which the government of **LATHACH** is divided: the other two circles, Klagenfurt and Villach, correspond respectively to Lower and Upper Carinthia.

CARNIVAL, or CARNEVAL, from the Italian *Carnevale*, or Farewell to Flesh. It is properly a season of feasting, dancing, masquerading, and buffoonery, which begins on the Feast of the Epiphany, or Twelfth Day, and ends on Ash-Wednesday, when it is succeeded by the austerities of Lent. Some of the license of the Saturnalia of the ancient Romans is still detected in these long revels, which are now confined to Catholic countries, and seem to be rapidly declining even in them. Milan, Rome, and Naples were celebrated for their carnivals, but they were carried to their highest perfection at Venice.

The pleasant place of all festivity,
The revel of the earth, the masque of Italy.

In modern Rome the masquerading in the street and all the out-door amusements are limited to eight days during which people pelt each other with sugr-plums, and are treated with horse-races, in which horses run without any riders on their backs. After the races of the eighth day, masquers go about with tapers in their hands, every one trying to light his own at his neighbour's candle, and then blow out his flame. This is the last of their frolics, and about as rational as any part of a Roman carnival.

CARNIVORA (Zoology), a term generally applicable to any creatures that feed on flesh or animal substances, but more frequently applied to that order of manumiferous quadrupeds which prey upon other animals.

The forms of this order are varied, and the number of species considerable. Furnished, like man and the quadrumanus, with three sorts of teeth, and nails or claws on the feet, they entirely differ from those two orders in never having the thumbs of the anterior extremity capable of being opposed to the other fingers. The greater or less development of their molar teeth, as cutting or lacerating instruments, seems to determine the kind of animal food fitted for their support. Those carnivora which have their molars totally or partially tuberculated partake of a diet in which vegetables form a greater or less proportion, and those which have them serrated as it were with points live principally on insects. There are other modifications of these molars, fitting them for crushing bones or dividing animal muscles, according to the exigency of the animal; but in all, as a general rule, the articulation of the jaw does not permit of horizontal movement, the power being simply that of opening and shutting forwards and downwards, like a pair of shears.

General Organization.—The prevailing feature of the skull is the great development of the zygomatic arch, affording a base for the action of the powerful muscles that work the trenchant jaw; the orbit is not separated from the temporal fossa. The articulation of the bones of the forearm in most of the carnivora is so constructed as to allow of free motion, though in a degree inferior to that bestowed on the quadrumanus. The brain (cerebrum) is considerable in bulk, well marked, but without a third lobe, and does not cover the cerebellum; of all the senses, that of smelling seems to be in the highest perfection, the pituitary membrane being extended over a manifold labyrinth of bony plates. The intestines are comparatively short, the nature of their food requiring less elaboration than that necessary for the extraction of nourishment from vegetables.

Cuvier gives the name of *Carnassiers* (flesh-eaters) to the order, and divides it into the following families:—

1. CHEIROPTERA.

These, as he observes, have still some affinities with the quadrumanus, as is manifested by the pendulous genital organ of the male, and the position of the teats of the female on the breast. Their distinguishing character consists of a fold of the skin, which, rising at the side of the neck, is extended between the fore-feet and the fingers or

toes, so as to suspend the animal in the air, and, in those genera which have the bones of the hand sufficiently developed to spread a sufficient extent of this membranous skin, there is a power of executing all the evolutions required for flight. Strong clavicles and large shoulder-blades were required for this feat, and we accordingly find great strength and solidity thrown into those parts; but as the rotatory motion of the fore-arm would have been worse than useless, inasmuch as it would have weakened the force of the impulse of the membranous wing, and would have consequently lessened the power of flying, we find it almost entirely absent. Four great canine teeth are found in all the genera of this large family; but the number of their incisors varies. Some idea will be formed of the arrangement of the teeth in the cheiroptera from the following cut:—

[Skull of *Pteropus Keraudrenius*.]

In the cheiroptera, as we have seen, the teats are pectoral, but in all the rest of the families they are ventral. The next family in Cuvier's arrangement is

2. INSECTIVORA.

The lateral membranes with which the cheiroptera are furnished are no longer to be found in the insectivora, which still have clavicles, and their molars, like those of the first family, are serrated with conical points. In their dental system the position and relative proportion of their incisors and canine teeth vary. Some have long incisors in front, followed by other incisors and canines lower than the molars, a scale of dentition to be found among some of the quadrumanus (genus *Tarsius*), and approaching in a degree the dental system of the *Rodentia*. Others have large and widely-separated canines, between which are small incisors, the most ordinary disposition of the teeth in the *quadrumanus* and *carnassiers*. The feet are short, and their motions comparatively feeble: the male organ is furnished with a sheath, and the teats are ventral. There is no crecal appendage, and the entire sole of the foot is applied to the ground in walking. Their habits, resembling in a degree those of the cheiroptera, are frequently nocturnal and subterranean. Insects form their principal nourishment, and many of them, especially in cold countries, pass the winter in a dormant state.

[Skull of *Erinaceus Europæus*, common Hedgehog.]

But before we have seen the carnivorous organization in a comparatively mitigated state, but we now approach Cuvier's third family, the Carnivora, properly so called, which have every part of their frame, in the cats especially, formed for the destruction of other animals. In two of the tribes, but more particularly in one, viz. the Plantigrades, the carnivorous form is indeed somewhat modified; but among these three tribes we find the greatest harmony of parts, fitted for keeping down the numbers of the granivorous and phytophagous animals, to be anywhere observed among the mammalia.

3. CARNIVORA.

In this family we have the thirst for blood at its highest degree of development, and with it the power and the instruments for gratifying the appetite. Four large, long, and distant canines, separated by the intervention of six incisors in each jaw (the root of the second of the lower incisors being a little deeper planted than the others)—molars, either formed entirely with cutting edges, or constructed partly with blunt tubercles;—these, with the powerful mechanism of the jaw in which they are set, present a most formidable apparatus for finishing the bloody task which the rest of the frame of the carnivora is so nicely adapted for commencing and continuing. The more completely trenchant these molars are, the more completely carnivorous are the habits of the animal, and the different gradations may be in general safely traced by observing the proportional extent of

surface, considered with reference to its tubercular or cutting shape. The bears, which, taken as a whole, may be said to be capable of supporting themselves entirely on vegetables, have nearly all their molar teeth tuberculated. [BEAR.]

The anterior molars have the most cutting edges, and then comes a molar larger than the rest, with a tuberculated heel or process more or less developed, and behind it one or two small teeth almost entirely flat. With these small teeth the dogs, as Baron Cuvier has observed, masticate the grass which they occasionally swallow for medicinal purposes; and the same author agrees with M. Frederic Cuvier in naming the great molar above and its antagonist below *carnassières* or *flesh-cutters*, the anterior pointed molars *false molars*, and the posterior blunt molars *tuberculeuses* or *tuberculated molars*.

By observing these differences of dental form, the genera of carnivora are most surely established, and it may be laid down as a general rule that those carnivorous animals which have the shortest jaw and the least development of the *false molars* are those in which the sanguinary propensity and the destructive power co-exist in the highest degree.

Many of the genera apply the whole sole of the foot (particularly of the hinder one) to the ground in walking, and this sole is generally destitute of hair; these are called *Plantigrade*.

Others again walk on the tips of the toes as it were, and these, the *Digitigrade* carnivora, are endowed with great swiftness of foot. The clavicle in both is merely a bony rudiment suspended in the flesh.

Cuvier divides his *Carnassiers* into the four following tribes:—

1. *Plantigrades*.

These possess a great facility, from the structure of the sole, of rearing themselves up on the hind feet. Cuvier observes, that they participate in the comparative slow motion and nocturnal life of the Insectivora, and that they are, like them, deprived of a caecum. The greater part of those whose geographical distribution is confined to cold countries pass the winter in a dormant state. They have all five toes on each foot. [BEAR.] The following cut will serve as an example of the dental form and arrangement.

[Skull of *Moles vulgaris*, common Badger.]

2. *Digitigrades*.

This tribe is separated by Cuvier into two subdivisions.

Subdivision a.

The animals composing this subdivision have been called *vermiform*, from the comparatively great length and flexibility of their bodies and the shortness of their legs. Every one who has watched the serpentine movements of a ferret must have been struck with the great facility of motion given by this form, and its particular adaptation for passing through small openings and narrow burrows and turning therein. Like the former families they have no caecum, but, unlike them, they are not lethargic in winter. Though small, they are of indomitable courage and ferocity, and literally most blood-thirsty; for the greater part of them live principally upon that fluid. The subjoined cut will give an example of the general form of the skull and teeth.

[Skull of *Putorius Zorilla*.]

Subdivision b.

These have two flat tuberculated molars, behind the upper great flesh-cutter, which has itself a sufficiently large heel or process. Many of these live upon carrion, and all have a small caecum. [DOG.]

We refer to the next cut for a general idea of the dental system.

[Skull of *Canis Vulpes*, common Fox.]

3. *Cats (Felis)*.

In this tribe we have the destructive power most highly developed. The short round muzzle, the abbreviated and powerful jaw, and the retractile claws sheathed by means of elastic ligaments when the animal is in a state of repose, so that they are kept sharp and ready for action, form with the rest of the organization a destructive type of the highest order! All the cats have two false molars above and two below: their upper flesh-cutter has three lobes and a blunt heel or process within; while the lower one has two pointed and cutting lobes, but without any heel or process; and they have but one small tuberculated molar above without any corresponding tooth below. The species are numerous, and vary greatly in size and colour. [FELIS.] Subjoined is a cut of the skull and jaw of a royal tiger.

[Skull of *Felis Tig.*]

a. Teeth of upper jaw.

4. *Amphibia, or Amphibious Carnivora*.

Those who have seen a seal on the land will have noticed the comparative helplessness of the animal; for the short limbs enveloped in the skin only serve them by assisting their awkward shufflings when in that situation. But as they never come on the land excepting for the purposes of repose, basking in the sun, or suckling their young, their organization is adapted to that element in which the great portion of their life is spent. The moment the seal enters the water he is completely at his ease. Then the oar-like membranous hands and feet, or flippers, as some of our northern navigators not unaptly term them, the elongated body and moveable spine with its powerful muscular machinery, the narrow pelvis and the close waterproof fur, afford, when taken together, a model for swimming. The annexed cut of the skull of a common seal will illustrate the general form and arrangement of the teeth. [SEAL.]

[Skull of *Calcecephalus vitulinus*.]

FOSSIL CARNIVORA.

Remains of the mammiferous carnivora are found abundantly in the ossiferous caverns and osseous breccia. Those of a lion, a tiger, bears, a glutton, a weasel, a wolf, a fox, a dog, and hyænas, have been satisfactorily identified; but the bears, especially the great cavern bear (*Ursus Spelæus*) [BEAR], and the hyænas, seem to have been predominant in many of the localities.

CARNOT, LAZARE NICHOLAS MARGUERITE, was born of respectable ancestry at Nolay, in Burgundy, May 13, 1733. He entered the army in the corps of engineers in 1771, and at the time the revolution began, was known as a respectable and well-informed officer, who had gained the prize of the Academy of Dijon for an *éloge* of Vauban, and had refused large offers to enter the service of Frederick of Prussia. In 1791, he was elected to represent the *Pro de Calais* in the legislative assembly, and became a member of the military committee. He was one of those who voted the death of the ex-king. In 1793 he became a member of the committee of public safety. His name does not directly appear as an advocate of, or agent in, any of the

excesses of the violent republicans; but as a man who stood high in place during these times of fury, he must remain under more or less of suspicion until the history of the revolution has undergone an analysis, which cannot perhaps be fairly made so long as the two great parties into which it divided Europe continue to exist in opposition. His attention was entirely directed, so far as his acts are evidence, to the affairs of his profession; he was in truth the war-minister of the committee. The most glorious period (in a military sense) of the republic was that in which he directed the raising of all the matériel of the army, and it was afterwards said of him that he had '*organisé la victoire*.' In 1793 he joined the army of the north with other deputies; the inefficiency of another general called him into action, and he was mainly instrumental in gaining the victory of Wattignies. In 1795 he was elected for seventeen different places, but was shortly afterwards proscribed, and sought refuge in Germany. He was recalled by the first consul, and was made minister of war. This post he lost when he voted against the consulate for life, and at the same time all the other military situations which he held. But after the Russian campaign, when France was on the eve of invasion, he offered his services to Napoleon, and received the command of Antwerp, which he held out until the abdication of 1814. When Napoleon returned from Elba, he wished to return to Antwerp, but the emperor is said to have told him that a machine would answer the purpose there; he was again appointed minister of war. After the restoration, he retired first to Warsaw, and then to Magdeburg where he died, August 2, 1823. He was twice a member of the Institute, and twice expelled, the first time by the directory, and afterwards on the restoration of 1814.

He published, in 1786, an '*Essai sur les Machines en général*,' and in 1808 his work '*De la Défense des Places Fortes*.' The latter is a remonstrance to the officers of the army upon the disposition which existed to consider a place untenable after the enemy had gained the glacis. He endeavours to show that the most serious part of an officer's duty only begins when the body of the place is attacked, and brings a large number of illustrations from ancient and modern warfare. He also explains the system of defence which goes by his name, namely, that of covering the guns from the enemy, and using them for vertical firing only, until the attack upon the body of the place begins.

The mathematical works of Carnot are remarkable for the elegance of his geometry and the clearness of his mode of expression. In his '*Réflexions sur la Métaphysique du Calcul Infinitesimal*,' he enters upon the consideration of the system of Leibnitz; and the main point of his theory is, that there is a compensation between the infinitesimals of inferior orders which are rejected on both sides of an equation. In his '*Géométrie de Position*,' Paris, 1803, his object is to explain the meaning of the negative sign in geometry, but at the same time he gives a large number of new and very general theorems. Here he is the inventor of that class of general theorems which have since been pushed to a great extent by MM. Poncelet, Dandelin, Quetelet, Chasles, &c. There is also his memoir upon the relation of five points taken in space, followed by his theory of transversal Paris, 1806. The essay on machines in general was enlarged and republished in 1803, under the title '*Principes fondamentaux d'Equilibre et du Mouvement*.' He published also some political tracts, and in particular, a justification of his public conduct in 1815.

We know of no references for the life and works of Carnot. We have taken dates from the '*Biographie des Contemporains*.' We take this opportunity of saying, that the sooner the French Institute publishes the *éloges* of the members who were not permitted to remain on its list by the restored and now re-expelled dynasty, the better for its own reputation.

CAROB TREE. [CERATONIA.]

CAROCOLLA. [IMACINEA.]

CAROL (*Carola*, Ital.), a song of joy. Boccaccio seems to have considered the term as synonymous with *ballata*, which, according to the dictionary *Della Crusca*, signified a song sung during a dance. It does not, however, appear so clear to us as it did to Dr. Burney, that Chaucer used the word in the sense in which the Italian novelist employed it. In England the term is now exclusively applied to a religious song or ballad, in celebration of Christmas, still sung during the festive season in many parts of the country, though now seldom heard in the metropolis.

CAROLINA, NORTH, one of the States of the North American union, lies on the Atlantic, extending from 33° 50' to 36° 30' North, and between 78° 39' and 82° 44' long. Its extreme length from near the source of the Tencasee river to Cape Hatteras is 420 miles, and its average breadth may be about 126. Its area is 49,000 square miles, or nearly equal to that of England without Wales. It is bounded by the ocean (300 miles), by South Carolina (308 miles), by Georgia (70 miles), by Tennessee (200 miles), and by Virginia (330 miles).

The western portion of this state, which is somewhat more than one-fourth of its surface, lies in the Appalachian mountains, and is traversed by several of its ridges. To the E. of them extends the higher terrace, or the hilly country, which occupies a little more than one-fourth of its surface. Between this region and the coast spreads the lower terrace, or the level country, which comprehends nearly one-half of the state. The boundary line between the two terraces begins on the N. at the Mundford Falls of the river Roanoke above Halifax, and extends S.S.W. to Smithfield on the Neuse, and to Aversborough on Cape Fear River, and terminates on the river Pedee between Rockingham and Sneadsborough.

The coast runs from the borders of South Carolina in a general E.N.E. direction to Cape Hatteras, and hence nearly due N. to the borders of Virginia. It exhibits a very peculiar character. Besides Cape Hatteras, it has two other projecting points, Cape Lookout and Cape Fear, which latter is on an island, about eight miles in length, and from one to three in width, called Smith's Island. By these three capes two open bays are formed, Onslow Bay and Raleigh Bay. Near Cape Fear is a deep inlet, formed by the mouth of the Cape Fear River; but along the whole shore of Onslow Bay, an extent of 120 miles, the flat coast is lined by low sandy islands, extending parallel to the shore at a distance of about a mile, the islands themselves being from half to one mile wide. This series of islands is traversed by several inlets, which are not practicable, except New Inlet and Bogue Inlet, and these only for small vessels. Near Cape Lookout, and between it and Cape Hatteras, the same character of coast continues, except that the islands are not so frequently broken by inlets, but continue in one place forty or fifty miles and upwards. The islands are also broader, measuring from one to two miles in width. But though along this coast the sandy islands extend in straight lines, the shores of the mainland behind them are broken by numerous arms of the sea, which penetrate to a considerable distance inland. There are also two extensive sounds, Pamlico and Albemarle Sound. Pamlico Sound extends from S.W. by W. to N.E. by E. seventy miles, with a mean breadth of fifteen, and terminates inland in the wide bays of the Neuse and Pamlico rivers. It is connected on the N.E. with Albemarle Sound, and opens into Raleigh Bay by Ocracoke Inlet, which may be considered as the mouth of the sound, and has fourteen feet water at mean tide. Albemarle Sound runs due W. into the mainland, about sixty miles by ten miles in width; but it sends off lateral branches, especially to the N., which run from twelve to fifteen miles inland. Albemarle Sound has no practicable connexion with the ocean. The peculiar character of the coast of North Carolina deprives it of good harbours, though there are several large rivers. Cape Fear, with eighteen feet water, is the deepest inlet that the state possesses. Owing to this circumstance the trade of central North Carolina, which is the most fertile portion of the state, has been turned into Virginia and into South Carolina.

The low country, stretching from 100 to 140 miles inland from the coast, exhibits two different aspects. Along the shores it is partly covered with extensive swamps, the largest of which are near Albemarle and Pamlico Sounds. Between them is the Alligator Swamp, more than fifty miles in length, and nearly thirty in breadth. Albemarle Sound is the Dismal Swamp into Virginia. The swamps S. of the Neuse river are of less extent; though several of them are from fifteen to twenty miles in diameter. The principal swamps are the Shelter and Green swamps. The soil is very fertile, and partly also of land compared to the Sunderbunds in the East. They are mostly covered with hickories (*Cypripedium disticha*), cedars, and pines (*Pinus taeda* and *Pinus strobus*), and land which intersect the swam have in general

oil, and much rice and cotton is raised on them. Between the hilly country and the hilly region extends, in breadth five miles and upwards, a tract of sandy land, which is mostly level; but in some places there are hills 200 feet above the adjacent country. The soil is sterile, and the surface overgrown with pine forests. Along the water-courses the soil is better, and the pines are replaced by oak, hickory, maple, beech, &c. This part of the country is only cultivated on the river-bottoms.

The upper terrace, or hilly country, lying between the pine-lands and the mountains, is, at a mean, several hundred feet above the sea, and presents an agreeable succession of moderate hills with gentle ascents, and of wide and extensive valleys. The soil of the valleys is good, consisting of a black and fertile mould, and yields rich crops of grain.

That portion of North Carolina, which is within the Appalachian mountains, is an agreeable alternation of hills and valleys. The mountains form two ridges, of which the W. is called the Iron Mountains (and part of it also the Stone, and another part the Smoky Mountains,) and the E. the Blue Ridge. Both are united at several places by short intermediate ridges. The Ararat or Pilot Mountain is east of the Blue Ridge, and about 16 miles N. of Salem; it is a solitary pyramidal hill, 1550 feet high, from the summit of which rises an almost perpendicular column to the height of about 200 feet. The rivers which rise between the two ridges run W. to the Tennessee river. The highest summits of the mountains exceed 3000 feet, and it is thought that the elevation of the whole country comprehended between them is 1000 feet above the sea. The soil is in general fertile in grain.

All the rivers have rapids where they pass from the hilly country to the low region. Their course above the rapids is rather swift; but below them no other current is observed than that produced by the tide, which ascends to the rapids. They offer therefore an easy navigation up to the hilly country; but sand-bars invariably occur at their mouth, on which there is less water than in the lower part of their courses, though they are generally shallow, if we take into the account their length and volume of water.

The Roanoke is formed by two branches, the Dan and Staunton, which rise and unite in Virginia. After their union the river runs S.E. by E., and forms, six miles above Halifax, the Mundford Falls. Lower down its course is excessively circuitous; it falls into Albemarle Sound. Its course is 150 miles; but each of its upper branches runs more than 100 before their junction. It is navigable nearly thirty miles from its mouth for vessels of considerable size, and boats from twenty to forty tons can ascend to the falls, which are seventy miles from its mouth. The Neuse rises in the centre of the upper terrace, and runs about 200 miles, first S.E., and then S.E. by E. Below Newbern it gradually spreads into a semicircular bay, which opens into the wider expanse of Pamlico Sound: it is navigable for boats in the greater part of its course. Between the Roanoke and the Neuse is the Tar, which also enters Pamlico Sound. Cape Fear River rises on the E. border of the mountain region, and flows by a general course S.E. for 250 miles, till it enters the Atlantic about ten miles N. of Cape Fear. It is navigable for vessels drawing ten or eleven feet to Wilmington, 34 miles from the sea; and sloops may ascend to Fayetteville, which is 95 miles higher up.

The climate varies in the three natural divisions of the state. In the mountain region the frost sometimes lasts three or four months; but is not much felt in the hilly country, and still less in the low plain. The summers are hot and sultry in the plain; and the exhalations from the swamps render it unhealthy from June to October. In the hilly region the heat is moderated by cool breezes. The changes of temperature are sudden and frequent, a cold night being often succeeded by an intensely hot day. The climate of the mountains is very temperate and healthy. The difference of the climate influences the agricultural products. On the hot plain cotton is the staple production; rice, so extensively cultivated; and indigo to a small amount. Farther westward these crops are superseded by wheat, Indian corn, and other species of grain, as well as by flax and tobacco. In the mountain region, grain, including Indian corn, is the principal object of cultivation. The fig-tree and the peach generally succeed; and in the western districts apples and pears are plentiful. The pine forests yield a great quantity of turpentine, tar, and pitch; and among the wild growing plants are the ginseng, sassa-

parilla, myrtle, and sugar-maple. The wild vine is found all over the country, and in some parts the vine has been successfully cultivated. All the domestic animals of Europe are bred; and swine are reared in great numbers. Wild animals were formerly very numerous, especially deer, bears, &c.; but except wolves and wild cats, few of them now remain. In the upper country the wild turkey is still common, and sometimes weighs from twenty-five to thirty pounds. Snakes occur everywhere; but the alligator inhabits only the swamps and lower parts of the rivers: it sometimes attains a large size, and attacks men. The Roanoke abounds with rock-fish, some of which weigh from sixty to seventy pounds.

The mineral wealth of this state has lately risen to importance. It contains the richest portion of the gold district, which extends at the foot of the eastern declivity of the Appalachian Mountains between 32° and 36° N. lat., the metal has only begun to be worked in the course of the present century, but a considerable produce has been already obtained. In 1804 native gold was for the first time brought to the mint of the United States, and from that year to 1823, inclusive, the average annual amount received at the mint did not exceed 2500 dollars. In 1824 it rose to 5000 dollars, and in 1830 to 518,000 dollars: in 1833 it had further increased to 868,000 dollars. Of this quantity more than one-half, or 568,000 dollars, were got in North Carolina. It is said that not more than one-fourth of the produce is brought to the mint. If this be true, the mines of North Carolina yield an annual produce of nearly three millions and a half of dollars. The chief gold district is situated on both sides of the river Yadkin or Pedee, in the counties of Davidson, Rowan, Cabarrus, Montgomery, and Mecklenburg, all of which belong to the hilly portion of the country or the upper terrace. Iron is abundant in the hilly and mountainous districts.

The native tribes have disappeared, except a few families of the Tuscarora tribe who live near the western extremity of Albemarle Sound in Berke county. They amounted, in 1820, to 3100 individuals. The population is composed of whites and blacks: some of the blacks are free, but the great majority are slaves who cultivate the soil. In 1820 the population amounted to 835,000 individuals, among whom were 14,600 free negroes and 205,000 slaves. According to the census of 1820, it was found, that in the hilly district 18, in the plain 12, and in the mountains a small fraction above 7 persons lived on each square mile. The coloured race is comparatively most numerous on the low plain, becomes less so on the hilly region, and least of all in the mountainous tracts. The population, according to the latest statements, is 737,987, of whom 245,600 are slaves, and 19,543 free persons of colour.

Raleigh, on the Neuse, the capital of the state, is regularly built, but contains only 2000 inhabitants. The largest place is Newbern near the mouth of the Neuse, which contains 4000 inhabitants, among whom are many Swiss families, who have named the town after the town of Bern in Switzerland. Fayetteville, on the Cape Fear River, carries on a considerable commerce, and has 4000 inhabitants. Wilmington, not far from the mouth of Cape Fear River, is also a thriving place, with 3000 inhabitants.

The exports consist of live cattle, tar, pitch, and turpentine, lumber, Indian corn, cotton, tobacco, pork, lard, tallow, bees-wax, myrtle-wax, ginseng, and medicinal roots and plants; most of these are sent to South Carolina and Virginia to be exported thence. A small portion is exported from Wilmington.

The instruction of the poorer classes is less attended to than in many other states of the Union. Though there is a literary fund, it is still inconsiderable, and has not yet so far increased that, according to the laws enacted by the legislature, it can be applied to the instruction of the poorer classes. The children of the coloured people, who in 1830 were calculated to amount to 75,000, between the ages of five and fifteen years, are excluded by the laws from receiving instruction. The instruction of the upper classes is better attended to, but is nevertheless still in a low condition. There is a university at Chapel Hill, 28 miles W.N.W. of Raleigh. It was incorporated in 1793, and first conferred degrees in 1797; it is pretty well endowed, but the number of pupils is small: and a military academy at Mount Airy.

A small English colony was settled on the Roanoke in 1587,

but it is not known what became of it. The first settlement was made in 1650 by some whites from Virginia. After other settlements the colony received a representative government in 1667, two years after which the constitution called 'Locke's Scheme of Government' was tried but soon abandoned. [CAROLINA, SOUTH.] The present constitution was adopted in 1776.

The legislative body consists of a Senate and of a House of Commons. One senator and two members of the House of Commons are annually chosen by each of the 63 counties; and one member of the House of Commons by each of the towns of Edenton, Newbern, Wilmington, Salisbury, Hillsborough, and Halifax. All freemen 21 years of age, who have been inhabitants of the state for 12 months preceding the election, vote for members of the Commons' House; but a freehold of 50 acres of land is a necessary qualification to vote for a senator. The two houses by joint vote annually elect the governor, who with the council of state, which is elected in the same way, forms the executive. The judges of the supreme and superior courts are appointed by joint vote of the two houses, and hold their office during good behaviour. The state sends two members to the senate in congress and thirteen to the house of representatives.

(Darby; Silliman's Journal; Mining Review; Woodbridge's Annals of Education.)

CAROLINA, SOUTH, one of the United States of North America, lies on the shores of the Atlantic, between 33° and 35° 10' N. lat. and 77° 45' and 83° 10' W. long. Its greatest length from its E. angle on the Atlantic to its extreme W. at the junction of the Savannah and Chatuga rivers is 275 miles, and its mean width nearly 120 miles. Its area is about 32,000 square miles, or nearly 3000 square miles more than Scotland with its islands.

On the E. it borders on the Atlantic with a coast line of 185 miles. On the S.W. it is separated from Georgia by the Savannah river for 270 miles, and on the N. is North Carolina, forming a boundary line of 300 miles.

South Carolina, like North Carolina, exhibits three different regions. The most western districts are covered with ridges of mountains and hills which belong to the Appalachian system. East of this mountain region extends the hilly country which is followed by a low plain that spreads over the eastern districts of the state to the ocean. But the proportion of the surface belonging to each of these regions differs considerably from that of North Carolina. The low plain comprehends little more than one fourth of the whole, and the remainder is almost equally divided between the other two regions. The line which separates the plain from the hilly region passes from Sneadsborough in North Carolina to Camden on the Wateree, and thence to Columbia on the Congaree, or to the junction of the Saluda and Broad rivers, and terminates on the Savannah at Augusta.

The northern portion of the coast of South Carolina to Winyaw Point forms an unbroken line of low sandy shore. South of that cape the shores, though low, are divided by a great number of inlets, which are the mouths of larger and smaller rivers, that generally divide into numerous branches before entering the Atlantic ocean, and by their numerous channels cut the shores into islands, the surface of which is very little elevated above high tides. The principal islands which line the coast are James', John's, Edisto, St. Helena, Port Royal, and Hilton. The line of coast, though generally uniform as to course from point to point, is very irregularly indented. The inlets dividing the islands as well as the rivers are comparatively very shallow, but the latter in every instance are deeper within than at their bars. In two points only can the coast be approached by large vessels. One place is Charleston harbour, which is formed by the junction of two small rivers, the Cooper and Ashley, the channel of which admits vessels of 16 feet draught. The other is Port Royal entrance, formed by the Broad River, the common estuary of some little creeks into which the tide ascends to a considerable distance. On one of the numerous inlets which wind through the labyrinth of creeks and islands with which this portion of the coast is chequered, is situated the port of Beaufort, which is spacious, but does not admit vessels so large as those which enter Charleston harbour. St. Helena Sound is nearly 8 miles wide, and runs 10 or 12 miles inland, but it is far too shallow to admit vessels of even moderate tonnage.

The plain along the sea-shore, which extends about 80 miles inland, is a uniform level. At its western border it has

a gentle rise and imperceptible ascent to about 200 feet above the sea. The soil, which on the arrival of the Europeans was covered with trees, but is now nearly devoid of them, is in general barren, consisting either of sand or a light blackish earth; but it is intersected, especially along the rivers, by fertile tracts which yield rich crops, especially of rice. A portion is covered with numerous swamps and morasses, which however are not so extensive as in North Carolina; they are overgrown with heavy timber, such as oak, ash, and cypress. On one side of all the rivers, and generally on both, the margin is a swamp from a half to three miles in breadth. To the west of this plain stretches a chain of sandy hills from 20 to 40 miles in breadth, beginning at the upper course of the river Pedee in North Carolina, and extending across the state to the banks of the Savannah. This tract produces nothing but small pine trees and some shrubs, except in the narrow valleys, to which the vegetable mould has been carried by the rains, and which are very fertile. Some of the sand-hills are 200 feet above the adjacent valleys. In this region the rivers form rapids. The country farther west is agreeably broken into hill and dale, and loose stones and rocks frequently occur on its surface. But the valleys and the lower declivities of the hills have a fertile black soil which produces good crops of grain. The more elevated parts of the hills are covered with oak and other hard trees. The hilly country gradually rises into mountains, which at the W. extremity of the state attain a considerable height, the Table Rock in Pendleton being said to be 4300 feet above the Atlantic ocean; the Oolenoy Mount is supposed to have a still greater elevation. The country between the ridges and mountains may at a mean rise to 1500 feet above the sea. The soil is thought not to be inferior to that of the hilly tract, even the greatest part of the heights being covered with tall trees of hard wood. Where it is cultivated it yields good crops of corn.

South Carolina is very well watered, its rivers being numerous, and some of considerable length. But though their volume of water is considerable, only two are fit for navigation in their lower courses, and even these only for small river boats, on account of their shallowness. But as the tide ascends to the sand-hills their navigation is easy. Her up numerous rapids render the transport of goods tedious, difficult, and expensive. The principal rivers are the Pedee, the Santee, and the Savannah.

The Pedee rises in the Blue Ridge in North Carolina, 36° N. lat., and between 81° and 82° W. long., and is first called Yadkin. It flows first N.E. by E. and then turns abruptly to S.S.E., in which direction it traverses the gold region of North Carolina. In South Carolina it continues in the same direction till its junction with the Little Pedee, whence it flows S.S.W. to the port of Georgetown, at which place it is called Winyaw Bay, and forms a wide estuary. As far as its course is included in this state it is navigable for river-boats. The Santee is formed by two great branches, the Wateree and the Congaree. The Wateree rises in North Carolina, a little W.S.W. of the source of the Yadkin, and is here called Catawba. It runs first E. and then S.S.E., in which direction it continues through South Carolina to its junction with the Congaree, having flowed more than 150 miles. It is navigable for boats of 70 tons burden to Camden, above which town are the Catawba Falls, where the river in 1½ mile descends 90 feet; but as the falls may now be avoided by a canal cut along the river, called the Wateree Canal, it may be ascended much higher, at least by river-boats. The Congaree, the other great branch of the Santee, is formed by the confluence of two rivers, the Broad River which rises in North Carolina and the Saluda, which takes its origin near the Table Rock, in the most western portion of South Carolina. By their junction near Columbia the Congaree is formed, and to this point vessels of 70 tons burden may ascend. The Congaree, running in a curve to the S.E., unites with the Wateree, from which point the river is called Santee. It flows first S.E. and then turns by degrees to E., and is navigable for large barges and steam-boats, but its mouth is shallow. Its course considerably exceeds 250 miles. The Savannah has its farthest branches in the western district of S. Carolina and the northern parts of Georgia, and forms, during all its course, a distance of 250 miles S.S.E., the boundary between both states. It has 17 feet water on its bar, and is navigable for large vessels to the town of Savannah, and for river-vessels and steam-boats to Augusta, above which town some rapids occur.

The climate of the low plain is very hot in summer, but comparatively mild in winter. Snow seldom falls near the sea, and is soon dissolved. The thermometer ranges between 17° and 83°. In the months of July and August the country is deluged with torrents of rain, accompanied by hurricanes, thunder, and lightning, and the air is loaded with noxious vapours, which generate bilious fevers and other diseases. The driest months are April and May, which are also the healthiest, but November is considered the most agreeable. The cold weather seldom begins before December, and terminates in March. The temperature is liable to sudden and great changes. In the upper country snow and frost occur annually, and the snow is sometimes from 12 to 18 inches deep, and remains on the ground for weeks and even months. The thermometer varies in summer between 65° and 85°, and sometimes rises to 94° and 95°. In winter it ranges between 20° and 55°, and falls to 10° or 11° during the greatest cold, which lasts but a few days. But this country is healthy at all seasons. Hurricanes sometimes cause great damage in the lower country, and earthquakes are felt from time to time, though not frequently.

The principal objects of agriculture in the low plains are rice and cotton, the latter being also cultivated in some districts farther inland. The sugar-cane is only grown with advantage in the Beaufort district, which forms the most southern part of the state. The fruits of the sea-coast are those of the southern countries of Europe, oranges, lemons, pomegranates, olives, and figs. In the upper country all the grains and vegetables of England are grown, with Indian corn in addition. The fruits are also those common in this country. Lately the cultivation of sesamum has been introduced. Among the wild plants the ginseng, gentian-root and wax-myrtle may be noticed. The forests contain many fine timber-trees, especially oak, beech, and hickory.

The domestic animals are those of Europe; black cattle are the most abundant. Many of the wild animals with which the country formerly abounded have disappeared; but still there are found in the mountainous districts, and even in some parts of the lower country, deer, bear, wolves, wild cats, foxes, squirrels, rabbits, raccoons, opossum and polecats. The wild turkey is pretty common in the upper country, and the wild pigeons come at certain seasons in great numbers. Seventeen kinds of serpents are known, among which is the rattlesnake; but they become every day less numerous. Alligators abound near the head of tide-water in the rivers, and grow to a great size.

No metal abounds, except iron, which is met with in several places in the upper country, and is of excellent quality. At some places copper and lead are found, but in small portions. Gold ore seems to be less abundant than in North Carolina or Georgia. The richest deposits occur along the affluents of the Broad River, near the boundary-line of North Carolina. Gold was brought from this district to the mint of the United States in 1831 to the value of 22,000 dollars, and in 1833 it had increased to 66,000 dollars. Among the other minerals slate and limestone are the most useful.

The number of Indians is very small. In the year 1829 they amounted only to 300 individuals, of the tribe of the Catawbas, who inhabit a tract of 15 square miles on both sides of the river of that name, near the boundary line with North Carolina. The remainder of the population consists of Europeans and Africans and their descendants. According to the census of 1829 the number of slaves was 256,457, and of free coloured people 6805, whilst that of the whites was 237,892. The low country was the most populous, averaging 20 individuals on each square mile; in the hilly country 14½, and in the mountains only 11½ were the average for each square mile. The population, according to the latest statements, is 581,185, of whom 315,400 are slaves, and 7921 free persons of colour.

The principal town of South Carolina is Charleston. [CHARLESTON.] The capital is Columbia, on the left bank of the Congaree, immediately below the junction of the Saluda and Broad rivers, which contains a good college and a large lunatic asylum, with a population of 4500. Hamburg, on the banks of the Savannah, opposite Augusta, lies in a district covered with plantations of cotton, and contains 3000 inhabitants. Beaufort, on the island Port Royal, has only 1600 inhabitants. George-town, on the upper end of Winyaw Bay, near the mouth of the Pedee, has some com-

merce, and 2500 inhabitants. Camden, on the Wateree, is inhabited by 2000 souls.

To facilitate internal commerce a few short canals have been cut, especially to avoid the rapids of the rivers. The most important is the Santee canal, by which the river Santee is united to the river Cooper, and consequently to the port of Charleston.

The exports consist of cotton, rice, tobacco, myrtle-wax, and hides, and the imports of manufactured goods, and the productions of the East and West Indies, with wines from the countries of southern Europe. [CHARLESTON.]

The first settlement of whites in North Carolina was about 1670; but the first permanent establishment was made in 1680 on the site of Charleston. Previously to this, in 1662, Charles II. had granted to Lord Clarendon and seven others all that part of North America between 31° and 36° N. lat.; shortly after, the northern boundaries were extended to 36° 30'. The proprietary government of Carolina lasted till 1719, when the two Carolinas were separated and a royal government was established. During the continuance of the proprietary government, Locke's scheme or constitution was tried, but not found to answer. The present constitution was adopted in 1790, since which date it has been twice amended.

Of late years the instruction of the lower classes has been attended to by the legislature. A sum of from 37,000 to 38,000 dollars is appropriated to the maintenance of a free-school system; and it is stated that from 8000 to 9000 children receive instruction gratis in about 820 free schools. The children of the coloured people, of whom there are 100,636, between five and fifteen years, are entirely destitute of education, the law excluding them from all instruction. The middling and higher classes are much better instructed than in North Carolina or Georgia, and the college at Columbia enjoys considerable reputation. The college at Beaufort was formed by a charter in 1795; but it is nothing more than a respectable academy. There is also a college in Charleston, and two medical colleges. There are in the state three theological seminaries, and two learned societies.

The legislative body is composed of a senate and a house of representatives. The senators, 45 in number, are elected by districts and by ballot for the term of four years, but half the number vacate their seats every two years. The representatives, 121 in number, are chosen for two years. Every free white male citizen, twenty-one years of age, paying taxes, or having a certain freehold qualification, &c. has a vote in the election. The executive power is vested in a governor, elected by the joint vote of the legislature for two years. The chancellor and judges are appointed by joint ballot of the two houses, and hold their offices during good behaviour. The number of districts, which name is here substituted for that of counties, is 29. The state sends two members to the senate in congress, and nine to the house of representatives. (Darby; *Mining Review*; Woodbridge's *Annals of Education*, &c.)

CARP. [CYPRINUS]

CARPATHIAN MOUNTAINS, *TIE*, constitute, the Balkan excepted, the most eastern of the numerous mountain systems which cover so considerable a portion of Europe. They form to a great extent the S.W. boundary of the vast plain which stretches over the N.E. of Europe, and thus constitute one of the most remarkable features of its physical geography.

The rock on which the castle of Presburg in Hungary stands, near the banks of the Danube, may be considered as the most W. point of the whole system. From this point the mountains extend N.N.E. towards the sources of the March and Waag, and between the two wide valleys in which these rivers flow. This range, which is about 100 miles in length by 16 or 18 in width, is of moderate height, not exceeding 2000 feet above the sea, and is called the Little Carpathians or White Mountains. The declivities are rather steep, and covered with forests. It is traversed by numerous mountain-passes, the most remarkable of which is that of *Lisza*, which connects Liza in Moravia with Lisza in Hungary. At its N. extremity occurs the *Iabunka*-pass, which leads from the valley of the Olsa in Moravia through that of the *Bisztritz* into the valley of the Waag.

At this pass, between 49° and 50° N. lat., the range turns E., and continues in that direction from 18° 40' to 23° E. long. Within these limits it bears different names. The most W. portion is called *Magura*; the middle, *Baba Gura*;

and the E. Beszkid, though it seems that the last name is frequently applied to all this range. Its length may be somewhat more than 200 miles, and its width about 20 or somewhat more. Its height increases towards the centre; the Jura Hora, the highest summit of the Magura range, attains only 4500 feet, but the highest summit of the Baba Gura, which is also called Baba Gura, rises to 5750 feet. Between the N.W. extremity of this range and the most E. point of the Sudetan mountains, which extend between Silesia and Bohemia, lies a plain of no great extent, traversed by the upper course of the river Oder; it has an elevation of about 1000 feet above the sea. A road traverses this range from the vale of the Arwa by the pass of Jorlanow into Galizia and leads to Cracow.

To the S. of the Baba Gura mountains, and divided from them only by a deep and not very wide valley, lies the highest part of the Carpathian mountains, called Mount Tatra. It is, properly speaking, not a range, but one enormous piece of rock, extending from W. to E. about 50 miles, and nearly from N. to S. in the middle, but decreasing in breadth towards the W. and E. This rocky mass is furrowed by numerous deep ravines on all sides. On the highest part of its surface, whose average elevation is estimated at about 7000 feet, rise several high summits, in the form of peaks, of which some pass above the line of perpetual congelation. The highest is the peak of Lomnitz, which attains 8675 feet above the level of the sea. The peak of Eisthal (Dale of Ice) is only about 36 feet lower, and on its N. declivity is the only glacier which occurs in the Carpathians. The number of peaks exceeding 8000 feet is about twelve, among which the Krywan is one of the most famous, though it does not exceed 8150 feet, and is lower than most others. This portion of the Carpathians presents generally bare rocks on its surface where it is not covered with snow; it contains several small alpine lakes. This enormous mass of rock is divided from all the surrounding ranges and masses by deep depressions. From the Baba Gura mountains it is separated by the valleys of the Arwa and Donajec, which, at their upper extremities, where they meet, hardly rise much more than 2000 feet above the sea. From the Beszkids, which extend farther E., the Tatra mountains are divided by the river Poprad, which surrounds the E. extremity, and, running N., joins the Donajec. The river Waag rises near the sources of the Poprad, and, running W., separates the Tatra mountains from the lower ranges, which extend farther S. and W., and which, from containing numerous mines of metals, have obtained among the German geographers the general name of Ungarisches Erzgebürge (the Ore Mountains of Hungary). These ore mountains occupy a much larger surface than all the ranges already noticed, inasmuch as they extend over all that part of Hungary which lies to the N. of 48° N. lat. between the river Hernad, which rises near the sources of the Poprad and Waag, and falls into the Theiss, and the bend of the course of the river Waag. Its most S. extremity, Mount Matra, stretches even S. of 48°. Its length exceeds 120 miles, and its width 70 miles; but the whole of this surface is not covered with mountains: it presents only a few ranges, running W. and E., and separated from one another by wide valleys, which at some places might be called plains. The range nearest to the Tatra mountains rises to a considerable height, Mount Dnabier attaining 6500 feet, and Kralova Hora, at the source of the Waag, about 5700 feet; but the ridges farther S. are much lower, and their summits rarely exceed 3000 feet above the plain of Hungary, which is about 350 feet above the level of the sea.

The high country extending E. of the river Hernad runs to 24° E. long. due E.; it then declines to E.S.E., and where it approaches 48° N. lat., to S.S.E., till it reaches the sources of the Pruth, Suczava, and Theiss, where the Carpathian mountains may be considered to terminate, and the Transylvanian mountains to begin. The W. portion of this elevated region is called Beszkids, but the whole is commonly comprehended under the name of the Forest Mountains (Waldgebürge) of the Carpathian range. In length it exceeds 200 miles, and its average width may be estimated at from 50 to 70 miles. The mountain-masses do not rise to a great height, nor are the declivities steep; on their upper surface they do not exhibit high peaks, but extend in uneven plains, on which a few elevations, with a very gentle ascent, rise considerably above them. The rivers do not run in longitudinal valleys, as between

the ranges farther E., but descend from the sides of the mountains, forming nearly right angles with their general course. On their N.E. side extends the great plain of E. Europe. Only two ranges, of no considerable length and height, branch off from the Forest Mountains, and traverse this plain to some distance. One of them leaves the principal range between the sources of the Saan, an affluent of the Vistula, and those of the Dniester, where 49° N. lat. is cut by 23° W. long. It runs for a short distance (about 10 miles) N.N.W., but then turns E., passes S. of the town of Lemberg, and, dividing the Russian governments of Volhynia and Podolia, advances towards the Dniester, on whose banks it continues in a direction S.E. to the catenets between Kidak and Alexandrowska, where it traverses the river and causes numerous impediments in the navigation. This branch is in no place high, and becomes very low as it enters Russia. At the sources of the Pruth, and between them and those of the Sereth and Suczava, several lateral branches set off to the N.E. and E., which render the surface of that part of Galizia, which is called Buckowina, extremely uneven; but they do not extend further than to the banks of the Dniester and Pruth, with the exception of one range, which divides these two rivers, and terminates in low hills, N. of Kisheneff, the capital of Bessarabia. In Buckowina they are called Czorno mountains.

The most remarkable ridge, branching off to the S., is the Telkabanga mountains, which are united to the main range at the sources of the Hernad and Bodrog rivers, and run between these rivers nearly to the junction with the Theiss, a distance of about 90 miles. The average width does not exceed 10 or 12 miles, and its elevation is not great, especially to the S., where it terminates with the hills, on which the wine of Tokay is grown.

Two great roads pass over the Forest mountains. The most western runs N. in the valley of the Bodrog, and traverses the mountains between Sztrapko and Dukla by the Dukla pass. The other road, farther E., unites Hungary with E. Galizia, and the town of Munkacs with Lemberg, traversing the pass of Vereske.

Only an inconsiderable portion of the Carpathians is of primitive formation. This is especially the case with the Tatra mountain and the ridges S. of it, which are composed of granite, gneiss, and mica slate. By far the greatest part of the W. range belongs to the transition formation, and is rich in metals. The Forest Mountains consist almost entirely of sandstone and slate, and contain only iron in abundance and a small quantity of copper.

The Carpathian mountains are richer in metals than any other mountain-system of Europe. Gold is got from the mountains which surround the valley of the river Gran, at Botza, Kremnitz, Königsberg, and Shernitz, probably more than 1000 mares annually, the whole produce of the Hungarian mountains being estimated at 2000 mares. Silver occurs in considerable quantity in the same places; and the annual value of the silver mines may amount to 20,000 or 30,000 mares: 92,000 mares are obtained from all the Hungarian mines. (A mare is 12 ounces.) Copper is very abundant, and occurs in numerous places between the Gran and Hernad. Its annual produce is about 2000 tons. Lead is found in great abundance in all the silver mines, and also in other places. Iron occurs over the whole system, but more especially in the Forest Mountains, and is worked with great advantage in many places. Quicksilver, zinc, antimony, arsenic, and cobalt are also extracted, and some of them in considerable quantity.

Several precious stones occur, among which the opals, found in the district of Sarosh, in the valley of the Hernad, are much esteemed; those collected near Tokay, Kremnitz, and Kaschau have less value. The chalcedonies and garnets are also much valued.

Perhaps in no part of the globe is there such an extensive salt-rock formation as that which lies on the lower declivity of the N. and N.E. descent of the mountains, beginning at the town of Wieliczka, S. E. of Cracow, and extending round the chain E. and S.E. to the boundary of Wallachia; its length cannot fall short of 600 miles; its width it varies very much. Its depth is conjectured to be upwards of 120 fathoms, at least this is the depth at Wieliczka and Rochna, the only two places where it is worked by the Austrian government. But in many other places salt is obtained by boiling the water of salt springs.

The Transylvanian mountains, which begin at the sources of the rivers Theiss and Suczava, and by running first

S.S.E. and then nearly W., inclose the principality of Transylvania, are commonly considered as the E. portion of the Carpathian system; but as no just idea can be formed of the different ranges composing it without a detailed description of the country traversed by them, the description is placed under TRANSYLVANIA. (Hoffmann, Csaplovics, &c.)

CARPEL. If the fruit of a pnyony is examined it will be found to consist of two or more hollow bodies terminated by a stigma, and containing vegetable eggs or ovules; taken collectively these are called a pistil, but each separate body is a carpel. A carpel is theoretically a transformed leaf, with its edges brought into contact, united, and generating ovules at the inside of the suture, while its midrib is lengthened and distended as a stigma. If several carpels are arranged in the centre of a flower they have exactly the same respective position as the same number of leaves would have; and their sutures and stigmas are placed in the same position as the united edges and distended points of so many leaves would be placed. Supposing these carpels to grow together by their sides their sutures will then be, with the ovules that belong to them, in the centre of the body formed by such a union. Upon these and similar considerations turns the beautiful modern theory of the real nature of the fruit of flowering plants, and the apparently paradoxical assertion that the fruit of the peach, the pea, and the plum, are merely transformations of the leaves of those plants. (See Lindley's *Introduction to Botany*, ed. 2nd, p. 166, &c.)

CARPENTARIA, THE GULF OF, is an extensive open bay on the N. coast of Australia, between 10° and 17° S. lat., and 136° and 142° E. of Greenwich. On its E. and S. shores a level country extends far inland, but the W. coast is high. It is not visited by European vessels, but the Malays of the Sunda islands and the Chinese resort to it for the purpose of taking sea-slugs. This gulf was discovered and surveyed by the Dutch general Carpenter, whose name it bears, and was more accurately laid down by Captain Flinders in 1803.

CARPENTRAS, a city of France, once capital of the Comté Venaissin, subject to the pope, now the chief place of an arrondissement in the department of Vaucluse. It is on the Auzon, a feeder of the Nesque, which flows into the Ouvèze, and ultimately into the Rhône: it is in 44° 3' N. lat., and 5° 4' E. long., about 360 miles from Paris in a straight line, or about 426 miles by the road through Auxerre, Châlons-sur-Saône, Lyon, Valence, and Orange.

Carpentras is mentioned under the name of Carpentoracta by Pliny, who assigns it to a people called by him Memini. Ptolemy speaks of a people called *Mimynoi*, to whom he assigns a city called Forum Neronis. It has been consequently inferred by Valois and others that Carpentoracta was the Gallic, and Forum Neronis the Roman name for the same place; and in this opinion we are disposed to coincide, notwithstanding the objections of M. D'Anville, who would identify Forum Neronis with Forcalquier. Whether the town was or was not a Roman colony has been much disputed. There are scarcely any remains of its ancient buildings: the scanty relic of a triumphal arch was in the seventeenth century incorporated into the episcopal palace then built by the bishop, the Cardinal Bichi, and transformed into a kitchen fire-place; by a strange transition it has since formed part of the gaoler's apartments, the palace itself having been converted into a court of justice. The remains of this arch render it clear that it was once magnificent, but the sculptures are much defaced by the hand of time. Its erection has been variously ascribed to Marius, to Domitius Aenobarbus, who defeated the Allobroges in this neighbourhood, and to Augustus; but all is mere conjecture.

In the middle ages this town shared the usual fate of those around; it became the prey of the barbarians of the north, and of the Saracens; but rising from these overthrows, it grew into importance. It was for about a year (A.D. 1313-14) the residence of the papal court, and perhaps would have continued to be so, had not a fire, caused by a tumult in 1314, rendered it uninhabitable. Carpentras was at this time in the dominions of the pope, to whom it had been ceded by the peace of Paris, A.D. 1228; but the temporal as well as the spiritual jurisdiction of the city was in the hands of its bishop: the temporal jurisdiction was ceded to the pope A.D. 1320. Predatory bands of undisciplined soldiers infested the town and neighbourhood in the 14th and 15th centuries; and in 1532 it was

considerable army under the Baron des Adrets, one of the leaders of the Huguenots; but the vigorous defence of the town induced the baron to raise the siege. In 1791 the city with the county Venaissin was ceded by the pope to the French.

The situation of Carpentras is very agreeable; it overlooks a beautiful district abounding with olive-trees. The town is still surrounded by its ancient walls, and would be handsome if its streets had been better laid out. There are four gates: that of Orange is surmounted by a lofty tower. Among the public buildings may be mentioned the hospital, the front of which and the vaulted ceiling of the staircase are much admired; the ci-devant episcopal palace; the cathedral, adorned with columns taken from a temple of Diana at Venusque; the aqueduct, a modern erection of considerable extent, which supplies the town with water; and the public fountains, by which the water is distributed.

The population of Carpentras in 1832 was 6294 for the town, or 9817 for the whole commune. Among these are many Jews, who have a synagogue here. With a liberality honourable to the papal government, the Jews were in the middle ages allowed to practise medicine and to engage in public affairs as well as private business; but the remonstrances of the states of the county compelled the pontiffs to withdraw these privileges about 250 or 300 years since. After the restrictions thus imposed on their pursuits, the Jews devoted themselves to commerce, and their numbers increased so that the quarters of the city to which their habitations were limited became extremely crowded. It is likely the population of Carpentras has declined of late years: Expilly (A.D. 1762) and Vaysse de Villiers (A.D. 1813) gave it at 12,000. The trade of the town is considerable: spirit of wine and aqua-fortis are made; and a great deal of business is done in madder, wine, and the other productions of the department. There is a considerable market on Friday.

The town has a public library, said to contain 25,000 volumes and 800 MSS.; a public school; a cabinet of medals; a collection of engravings and antiquities.

The bishopric is very ancient, perhaps it was erected as early as the third century: the see no longer exists, the department being included in the bishopric of Avignon.

The arrondissement of Carpentras had, in 1832, a population of 51,269.

CARPET. The consumption of carpets in Great Britain up to about the middle of the last century was so very trifling that, as a manufacture, it was hardly deserving of notice; and although now so essential to our warmth and comfort, a few generations since carpets were only partially used in the mansions of the rich. Only a few manufactories, of which that at Wilton was the most important, existed in different parts of the kingdom; and at Kidderminster, which is now the principal seat of the trade, and where at least 5000 persons are employed in its different branches, the carpet manufacture did not commence before the early part of the eighteenth century. We doubt whether at the commencement of the nineteenth century one-fourth of the present number of carpets was manufactured.

We purpose to give here some account of the different descriptions of carpets at present manufactured in Great Britain, and also of the mode of manufacturing each.

In all kinds of carpets the materials are dyed before they are put into the loom. A very curious and ingenious attempt was made three or four years since to print the worsteds while in the process of weaving. A patent was taken out and the object was partially accomplished, but there are so many difficulties to encounter that it is scarcely probable this plan will be brought into general use.

The following kinds are now made in Great Britain:—Axminster, Venetians of different sorts, Kidderminster or Scotch, British or damask Venetian, Brussels, and Wilton or Pile carpeting. These names do not always denote either the present or original place of manufacture. Brussels carpets were introduced into Kidderminster from Tournay in 1745; and we do not know that Venetians were ever made at Venice. Wiltons (which are in fact Brussels carpets) were made on the continent before they were introduced at Wilton; and what are called Kidderminster are made in the greatest quantities in Scotland or Yorkshire.

Axminster carpets are made, we believe, solely at Axminster: they are usually made in one piece, according to the dimensions of the room for which they are required. The warp or chain is of strong linen, placed perpendicularly between two rolls or beams which turn round and enable the

chain to be rolled from off one beam and on to the other as the weaving of the carpet proceeds. Small tufts or bunches of different coloured worsted or woollen are tied to or fastened under the warp; and when one row of these tufts has been completed the shoot of linen is also thrown in and finally rammed down. Another row of tufts is then arranged in such a manner as, by a change of the colours, to form a further portion of the pattern. To guide the weaver as to the position of the colours, a small paper design or drawing constantly hangs before him, from which he works. The tedious nature of this process, and the quantity of materials which it consumes, render this kind of carpet very expensive, and the whole quantity manufactured is trifling. Real Turkey carpets (so called to distinguish them from those Brussels, the patterns of which are made to imitate them) are manufactured in a similar manner, and they are regularly imported, though not in very large quantities. Finger or town made and Stormont rags are also formed with tufts put in as they are in Axminster carpets; but the warp or chain is laid horizontally, and a common loom, with its usual appendances of treadles, gearing, reed, lathe or batten, &c. is made to assist in the process.* In all these carpets the warp and weft, or, as they are called, chain and shoot, which are both of linen, are altogether concealed from the upper surface, the tufts of worsted or woollen being the only part that is visible.

Venetian carpets.—Here the warp or chain, which is of worsted, and generally arranged in stripes of different colours, is alone visible; the shoot, which is of a dark colour and usually black, is concealed between the upper and under surface. By using shoot of different sizes these carpets are sometimes made to assume the appearance of plaids or checks, and by the arrangement of the treadles a twilled or dotted appearance is at other times given to them. Venetians are generally used for staircase carpets, but the plaid kind are occasionally used for rooms. Although dots, waves, small figures, and plaids, are sometimes introduced, the general character of Venetian carpets is a simple stripe throughout. They do not come under the head of figured weaving, no machinery but that of the common loom being required for their manufacture. Woollen, linen, and cotton are all used for the shoot.

Kidderminster or Scotch carpets, or, as the Americans more descriptively term them, *ingrain carpets*, are wholly of worsted or woollen, or, as is most common, the chain is of worsted and the shoot of wool. The pattern is formed by the intersection of two or more cloths of different colours; but as these cloths may be woven in stripes of different shades by introducing at intervals shoot of different colours, the carpet is usually made to assume a great variety of colours. Wherever this is the case, however, either the upper or under surface must necessarily have a striped appearance, and the stripes will be seen running across the carpet. The process of weaving these is somewhat complicated, but we will endeavour to give some idea of its nature, and in our description we will confine ourselves to those in which there are only two cloths. These in fact form nineteen twentieths of the whole quantity. A few, called *three-piles*, or made with three cloths, for the North American market, and we have heard of one instance of *four-ply*, but we believe the manufacture, if ever accomplished, has been abandoned. Each cloth is perfect in itself, so that if one cloth were carefully cut away the other would remain perfect, and be in appearance like a very coarse baize. The process of weaving both cloths is carried on at the same time, and in each part of the carpet that cloth is brought to the surface which is required to produce that portion of the pattern. Now suppose the two colours are blue and white, and that the weaver in proceeding with his work is about to throw in the blue shoot—a common weaving he must raise by his treadles and gearing one half of the blue warp to form the cloth, but he must also raise the whole of the white warp in those portions of the carpet where the pattern requires that the upper surface shall be white—this has to be done by other machinery, as the quantity so to be raised varies with every shoot. After throwing in the blue shoot he has to prepare for the white one, and it is now necessary for him not only to raise, by the treadles, &c. one half of the white warp, but also by the machinery,

the whole of the blue warp, where blue is to form the upper surface. He next proceeds to throw the second blue shoot, and has to raise the other half of the blue warp (that which was raised before being now depressed), and also that part of the white warp which this next portion of the pattern requires for the upper surface. The second blue shoot having been thrown, he proceeds to the second white, and raises the reverse half of the white warp and the whole of the blue warp, where blue is to form the surface, and so on as before. The reader will readily perceive that the back of the carpet will necessarily be of exactly the same pattern as the front, but the colours will be reversed. What is blue on the upper surface will be white on the under, and that which is white above will be blue below. Till within a few years the machinery used to manufacture these carpets was of the most clumsy and complicated nature. A great improvement took place about twenty years since, by the introduction of barrel looms, which were constructed on principles similar to those of the barrel organ or musical box. Each pattern however required a change in the barrel and this process was somewhat tedious and expensive. These looms were therefore shortly superseded by the Jacquard machine, which has brought about a vast improvement in many respects, and enabled the largest and most complicated patterns to be accomplished with the greatest facility, accuracy, and beauty.*

British or damask Venetian partakes both of the character of Venetian and Kidderminster, though more of the former than the latter. The warp, as in Venetian, is the only part seen, whereas in Kidderminsters the shoot forms by far the greatest portion of what is visible. The consumption of British is however small, and perhaps hardly of sufficient importance to render a particular description necessary. They require machinery similar to that employed in weaving Kidderminsters.

Brussels carpets form by far the most important and increasing portion of the carpet trade. Brussels are composed of linen and worsted, the cloth or reticulated part of the structure being entirely of linen, which is formed into a kind of very coarse sampld cloth, with two threads of linen for the shoot (one above, and the other below the worsted). This will be best explained by a simple diagram of a section of the linen only, the worsted not being shown

in this sketch. The dots represent a transverse section of the shoot; the lines crossing one another are two threads of the warp. Now the worsted is firmly bound in between the upper and under shoot, or as in this sketch, between the two rows of dots, thus: the dotted lines

represent three ends of the worsted, of which there are usually five, each end differing from the others in colour. These ends, as they are technically termed, are composed of one, two, or three threads of worsted, according to the quality of the carpet: the average number is two. Taking it therefore at two, there will always be ten threads, two each of five colours, bound in between every reticulation of the linen. This gives substance, firmness, and solidity to the mass. Having endeavoured to give some idea of the structure and groundwork of the carpet, we must next proceed to explain the formation of the pattern. We have seen that we have five ends of yarn, each of a different colour, at our disposal in every part of the carpet. All we have to do is to bring to the surface that one of the five colours which is required to form that portion of the pattern, and to form it into a loop projecting above the surface. The section then assumes the appearance of the annexed sketch.

This sketch is in fact a section of a bit of Brussels carpet when complete. The business of drawing the required colours to the surface is performed by a child from ten to fifteen years of age, who is called the *drawer*, and is placed by the side of the loom for this purpose. Each worsted end is made to pass through a small brass eye,

* We presume our readers are acquainted with the construction of a common loom, such as is used for weaving cloth or calico; if not, we refer them to the chapter on Plain Weaving, in the volume on the 'Silk Manufacture' of Lardner's Cabinet Cyclopædia.

* A very particular and lucid description of the Jacquard machine is given in the chapter on Figured Weaving, in the volume on the 'Silk Manufacture' of Lardner's Cabinet Cyclopædia. The principle of the Jacquard machine is simple and beautiful.

called a mail, to which is attached a very fine cord. This cord passes over a pulley fixed at some height above the loom, and is brought down again by the side of the loom, and fixed to a thick stick or roll near to the ground. Now there are generally 260 ends of each colour in 27 inches, the usual width of the carpet; and with five colours in each place we have 1300 ends: there must therefore be 1300 brass eyes or mails, 1300 cords, and 1300 pulleys to each loom*. The pulleys are arranged with great accuracy and neatness in a frame, technically termed the box, which is placed at a considerable height above the mails. The cords being so numerous present a confused appearance to the spectator, but every one has its proper place, and can, when required, be readily traced by the weaver. Now by pulling the cords as they hang by the side of the loom, it is evident we shall raise the brass eyes connected with them, and also the worsted ends passing through those eyes; and all that is to be done is to pull such 260 of those cords as will raise the colours required, one end in each place. To accomplish this, a strong thread is made to twine around the cords, and separate those which are required to bring the proper colours to the surface. This thread is called the lash, and one lash is necessary for every set or row of colours that has to be drawn to the surface. These lashes are taken in regular succession till the pattern is complete. The number of lashes must therefore vary with the length of the pattern; and in a pattern a yard long there are usually 320 lashes.

In describing the process of weaving, we will suppose the loom at work, and every thing ready for proceeding. The drawer takes hold of the first lash with his right hand, and gently draws towards him the 260 cords confined by it: this separates them from the others, and he then firmly grasps them with his left hand, and having loosed the lash, he with both hands and the weight of his body draws the cords down. The 260 ends required for the first portion of the pattern being thus raised above the surface, he with his left hand inserts under the raised ends through the whole width of the carpet, a light wooden board called the sword. The sword is about five inches in width, and being made to stand on its edge, it retains the raised ends about five inches above the surface. The drawer then looses the cords, and prepares for the next lash. When the sword is in, and the required colours thus raised, the weaver using both hands carefully raises any of the ends which stick down by reason of the roughness of the material or otherwise; and having thus formed a clear opening, he inserts the wire under the raised ends throughout the whole width of the carpet. The wire is round, and in diameter about the twelfth part of an inch. After the wire is inserted the sword is withdrawn, and the weaver by means of his treadles and gearing brings above the surface one-half of the linen chain, the other half and the whole of the worsted being depressed. The shuttle with linen shoot is then thrown in. The weaver next raises the reverse half of the linen chain, and the whole of the worsted, the half of the chain before raised being now depressed, and then throws in the second or under shoot. Between throwing the first and second shoot, as well as after the second is thrown, the weaver gives two or three severe blows with the lay or batten, which is very heavy, and he thus forces the materials closely together, and gives firmness and solidity to the mass. The weaving of this wire is now complete. The drawer then draws the next lash in rotation, and he and the weaver proceed as before. When a number of the wires have been thus woven in, they may be drawn out, and the carpet is complete. Care must however be taken not to draw out the five or six wires that have been woven last, or the fresh made loops are in danger of being drawn down, and the carpet blemished. It is necessary that each end of worsted should work independently of the others, and to accomplish this every end is wound on a separate bobbin, and the bobbins are arranged in frames at the back of the loom, with a small leaden weight or bullet to each bobbin to keep the worsted in a proper degree of tension. This adds greatly to the cumbrous nature of a Brussels loom. The linen chains for Brussels and Wilton, as well as the chains for all other descriptions of carpets, are wound on beams as in other kinds of weaving. The Jacquard machine, before referred to, has been constructed so as to take

the place of the drawer, pulleys, cords and lashes; and there is little doubt that this machine will soon be brought into general use for that purpose.

Wilton or pile carpet differs from Brussels only in this; that the wire, instead of being round, is flattened, and has a groove in the upper surface thus **V**; and instead of its being drawn out, a sharp knife is drawn along the groove, and the wire is thus liberated. By this means the loops of worsted are all cut through, and the carpet assumes a velvety appearance. The shape of the wire renders it possible to make Wilton or pile carpet of almost any thickness and quality; but this is not the case with Brussels. The manufacture of Brussels carpets was introduced into Wilton soon after its introduction into Kidderminster: the Wilton carpets, being originally a better description of goods, were distinguished by the name of cut or Wilton carpets.

The chief export trade for carpets is to the United States of America; but they are also sent to most parts of the continents of Europe and America. There are no data from which we can calculate either the probable consumption of carpets in our own country, or the amount of the whole manufacture. We therefore make our own statement with considerable diffidence; but we are inclined to suppose the whole number of looms in Great Britain does not exceed 4000; and the value of carpets made in the year, we would estimate at about a million sterling. By far the greatest quantity of Brussels is made in Kidderminster: what are called Kidderminster or Scotch are made in the largest quantities in different parts of Scotland and the north of England.

CARPENUS, the hornbeam, a genus of trees belonging to the natural order of *Cupulifera*, and distinguished obviously from the beech, the oak, &c. by its cupule being prolonged on one side into a leafy lobe, while its other lobes are shorter, and, as it were, abortive. *Ostrya* or the hop hornbeam differs in having an inflated membranous cupule surrounding each nut.

Four species are known:—

1. *C. betulus*, or common hornbeam, is an indigenous British tree very common in copses, and frequently pollarded by the farmer. When allowed to acquire its natural appearance it forms a graceful tree from 50 to 60 feet high, very often branching to within a short distance of the ground. In general appearance it resembles the beech, but it does not acquire the smooth plump bole of that tree, nor are its leaves so shining. Its wood is coarse, and unfit for cabinet-makers' work, on account of the large size of its medullary processes; but it is tough, and well suited for cogs, handles of tools, and for other purposes in which strength is required. It is much consumed on the continent as fuel. Like the beech, the hornbeam, if stunted, retains its withered leaves all the winter, and as it bears clipping and close pruning remarkably well, it is much employed for hedges where winter shelter is required. The distinctive character of the common hornbeam is, leaves oblong, cordate, oblique at the base, doubly serrated, smooth, with the veins of the under side, which is very shining, downy at the axils. Lobes of the cupules nearly entire. A cut-leaved variety is known in gardens.

2. *C. Americana*, or American hornbeam. Leaves ovate, oblong, obliquely cordate at the base, doubly or almost simply serrated, smooth, with the veins of the under side downy at the axils. Lobes of the cupules somewhat falcate and serrated. Common from Lower Canada to the Carolinas, and extremely frequent in almost all soils except pine barrens and swamps. It is a smaller tree than the European hornbeam, not usually acquiring a greater height than 15 to 20 feet, although specimens have been found as much as 30 feet high. From the small size of this species it is little used by the Americans; its wood appears however to have the same properties as that of *C. betulus*.

3. *C. orientalis*, or Oriental hornbeam. Leaves oblong, doubly serrated, cordate, and very little oblique at the base; when young, rather downy: lobes of the cupules coarsely and unequally serrated. It is a bushy tree of small stature found in the eastern parts of Europe, and on the mountains of Caucasus. It is of no known use, and principally differs from the common hornbeam in its downy leaf stalks, and green much-lacerated cupules. It is the *C. duinenensis* of Scopoli.

4. *C. viminea* is related to the last, but has taper pointed leaves with simple or nearly simple serratures, and less deeply serrated lobes to the cupules. It is a large hand-

* This is not always the case. Two cords attached to different mails are usually united before they reach the pulley, so that in this case there are only 650 pulleys and 650 cords passing over them. In these looms the pattern must be repeated twice in the width of the carpet.

some tree with weeping branches, found on the mountains of Nepaul.

5. *C. faginea*, from the same country, is distinguished from the last by its woolly leafstalks and simply setaceous serrated leaves, which are but little acuminate.

CARPOBALSAMUM, a kind of volatile aromatic oil, said by Bruce to be furnished by the *Balsamodendron Giladense*. It is produced by the nuts, which have a fleshy kernel yielding the balsam by simple expression. It should be employed while recent, otherwise it loses its odour and becomes inert.

CARPOLOGY is a division of botany comprehending what relates to the structure of seeds and their seed-vessels, or what is commonly called fruit. The subject is usually treated of incidentally in all elementary botanical works; and with much care by Mirbel, in his 'Eléments de Botanique;' and Lindley, in his 'Introduction to Botany.' The only special works upon the subject are Gærtner 'De Fructibus et Seminibus Plantarum,' and Richards's 'Analyse du Fruit;' the latter however is in a great measure obsolete, in consequence of the author having been unacquainted with the true theory of the structure of fruit.

CARRARA, a town and territory of Italy, with the title of principality, is annexed to the neighbouring duchy of Massa, both of which belong to the present Duke of Modena, whose mother, Beatrice d'Este, was the last offspring of both the houses of Este and Cibo, the latter of which held the sovereignty of Massa and Carrara from the early part of the sixteenth century. [INNOCENT VIII.] The territory of Carrara consists of about thirty square miles, mostly mountainous, but well cultivated, and with a population of 11,500 inhabitants. It is bounded on the N. by the territory of Fivizzano, which belongs to Tuscany, E. by the duchy of Massa, S. and S.W. by the Mediterranean, and W. and N.W. by the province of Lunigiana, which partly belongs to the Sardinian state, and partly to Modena. It extends in length about eight miles from the sea, to the summit of the Monte Sagro, N.E. of the town of Carrara. The Monte Sagro is 5540 feet high, being one of the principal summits of the Alpe Apuana, a group of the Ligurian Apennines. [AVENNINUS.] From the S. side of this mountain several lower projections or buttresses extend to the S.W., being separated from each other by narrow valleys, drained by the Torano, Bedizzano, Canal Grande, &c., all of which unite near the town of Carrara, and form the river called Carrone, which flows by Avenza into the sea, about four miles below Carrara. These lower ridges furnish the well-known white marble of Carrara. There are more than 100 different quarries of marble of various qualities, some of which is streaked with purple or blue, and is called Bardiglio. Some of these quarries, such as those of Fantiscritti and Canal Grande, were worked in the time of the Romans. The name of Fantiscritti comes from three figures of Jupiter, Bacchus, and Hercules, which are cut on the vertical side of a marble rock and near which are inscribed the names of several artists and travellers who visited this spot. An inscription was found in 1810, in the quarries of Colonata, of the time of Tiberius, with the names of the consuls from the year 16 to 24 of our era, and those of the decurions of the place, and of one Hilarius, Magister Villicorum, or superintendent of the workmen. In the time of Augustus, the marbles of Luna, for so they were called from the town of Luna, the ruins of which are seen about six miles S.W. of Carrara, were employed in the buildings of Rome (Strabo, p. 22; Casaub.); but the finer sort, for statues, was discovered about the time of Pliny, when it was substituted by the sculptors at Rome for the marbles of Paros and Pentelicus. After the fall of the empire, the quarries lay neglected till the twelfth century, when, the republic of Pisa having taken possession of this district, the works were resumed and furnished the marble for the school of Niccolò Pisani and his disciples. Since that time new quarries have been opened in succession. Those of Crestola, Cima, Cavetta, and Polvaccio supply the finest marble for statues; those of Ravaccione and Canalbiano furnish large blocks of coarser grain. The various streams turn a number of mills for sawing the marble. The material appears to be inexhaustible; 1200 workmen are constantly employed; the annual revenue is calculated at 750,000 francs, and the value of the exportations of the rough material is half a million. (Serristori, Neigebaur.) The blocks are carried down in carts, drawn by oxen, to the Spiaggia or beach of Avenza, where the storerooms are, and whence

the marble is shipped on board the vessels that anchor in the roads. In the town of Carrara are shops for the sale of common objects and ornaments of marble, which are worked by native artists. There is in the same town an academy of drawing and sculpture, which was founded by Maria Teresa, Duchess of Massa, the heiress of the Cibo family, who married in 1741 Rinaldo d'Este, Duke of Modena. The academy was transferred in 1815 to the ducal palace; it has a president and several professors, and a good collection of models. Many foreign artists repair to Carrara for the sake of purchasing the blocks which they require for their works, and which are rough-hewn on the spot.

The name of Carrara is supposed to come from 'Carra-ria,' which, in the Latin of the lower ages, meant quarries, and from which also the French 'Carrières' is derived. The town contains 5000 inhabitants, has a fine collegiate church, begun in the thirteenth century and finished in the fifteenth, also the church of La Madonna delle Grazie, rich in marbles, and that of S. Giacomo, annexed to the hospital, which has some good paintings. The principal square is called Alberica, from the name of the first prince of the house of Cibo, whose title was sanctioned by a diploma of the Emperor Maximilian II., August, 1568. A colossal statue of the last Duchess Beatrice, with a fountain, adorns the square. There are communal schools for elementary education, and a judge of prima istanza for both civil and criminal cases. The Court of Appeal is at Massa; where the governor of the whole province also resides: Avenza, the second town of the principality of Carrara, has 1900 inhabitants; it lies in a plain, about one mile from the sea, the lower hills around being all planted with vine and olive trees. The high road from Genoa and Sarzana to Lucra and Pisa passes through Avenza. There are besides ten other villages with from 200 to 900 inhabitants each. The principal agricultural produce is oil and wine; the corn raised on the territory is not sufficient for one-half of the consumption; the N. mountains are covered with chestnut and beech trees, and pastures. (Repetti, *Dizionario Geografico della Toscana*.) Near the village of Torano is a celebrated cavern, called *del Tanone*, rich in stalactites, which is described by Spallanzani. Carrara has produced several good artists; among others, Danese Cataneo, a sculptor and poet; the two Tacca, father and son, both sculptors, who flourished in the sixteenth and seventeenth centuries. Pellegrino Rossi, a distinguished living jurist, now professor at Paris, and author of the 'Traité du Droit Pénal,' and other works, is a native of Carrara.

CARRICK. [Ayrshire.]

CARRICK-ON-SUIR, partly in the barony of Iffa and Offa E. in the county of Tipperary, and partly in the barony of Upperthird in the county of Waterford, in Ireland, is a considerable town on the river Suir, which is here navigable from Waterford, and is about 85 English miles direct distance S.S.W. from Dublin. This town is known in the records as Carrick-Mac-Griffin, and was a place of considerable note soon after the conquest. Here are the remains of a fine castle built by Sir Edmund Butler in 1309 on the site of an old priory of the knights of St. John of Jerusalem. The same Sir Edmund, who was created earl of Carrick in 1315, built the bridge, which is still standing. In the hall of this castle the news of the rebellion of 1641 was first brought to the great duke of Ormonde, who resided here. Carrick-on-Suir was formerly celebrated for its flourishing manufactures of woollens, principally rattens and broad cloths, which in 1777 employed about 400 hands. At present the place is only remarkable for the fine scenery of its environs, which a late intelligent traveller considers superior to the vale of Clwyd, and for the wretchedness of its pauper population. All traces of manufacturing prosperity are gone, and the place can scarcely be said to have any trade. It has been proposed to improve the navigation to Waterford, as barges only can ply at present on the Suir, but nothing has yet been effected to turn the advantages of this fine river to due account. Population in the county of Tipperary, 6922; in the county of Waterford, 2704; total, 9626. In 1824 there were four Protestant and 13 Roman Catholic schools, educating 649 males and 484 females. The Roman Catholic free-school cost 1640*l*.

(There is no published history of the county of Tipperary, and the records for Munster have never been printed; information on this town is therefore scanty. See Young's *Tour in Ireland*; Inglis's *Ireland in 1834*; *Parliamentary Reports and Papers*.)

CARRICKFERGUS, the seaport town for the county of Antrim, constituting with its liberties the county of the town of Carrickfergus, in Ireland, situated on the W. shore or Antrim side of Belfast Loch, nine miles N.N.E. of Belfast, and 96 English miles direct distance N. by E. of Dublin. The county of the town, as laid down in the Ordnance Survey of Ireland, contains 16,699 statute acres and a population of 8698 persons. The county of the town and parish of Carrickfergus are co-extensive, with the exception of the plots of ground on which the castle, court-house, and gaol stand, which belong to the county of Antrim.

Carrickfergus Castle is supposed to have been founded by De Courcy about the end of the twelfth century, and is a place of considerable importance in the history of Ireland. From the middle of the fourteenth to the end of the sixteenth century it was the only stronghold north of Dundalk which remained uniformly in the hands of an English garrison, and to the loyalty of the townsmen of Carrickfergus is chiefly to be attributed the recovery of the Northern Pale in the reign of Elizabeth. The castle was besieged and taken by Edward Bruce in 1315; it is said that the garrison, before surrendering, were driven to devour thirty Scots whom they had made prisoners. In 1333 the Irish overran all the south part of the county of Antrim [BELFAST], and the garrison of the castle, with the inhabitants of the town that had arisen under shelter of its walls, were left alone in the midst of enemies. In 1386 the town was burned by the island Scots, and suffered again in 1400. In 1503 Gerald Earl of Kildare, lord-deputy, afforded some relief to the struggling colonists by garrisoning the castle. In 1555 the Scots, under Mac Donnell, Lord of Cantyre, laid close siege to the castle till July, 1556, when Sir Henry Sidney relieved the garrison with great slaughter of the besiegers. In 1573 the town was burned by Brian Mac Phelimy O'Neill, chief of Claneboy, who was hanged here along with Mac Quillan, chief of the Route, in 1575; the same year Sorley Boy Mac Donnell (a son of Mac Donnell of Cantyre, who had seized upon Mac Quillan's country a short time before) attacked the town and was repulsed with great loss. At this time the condition of the place is thus described by Sir Henry Sidney:—"The town of Carrickfergus I found much decayed and impoverished; no ploughs going at all, where before were many; and of great store of kyne and cattle belonging to the town, now few or none left; church and houses, saving castles, burned; the inhabitants fled; not above five householders of any countenance left remaining; so that their miserable state and servile fear was to be pitied; yet they are so comforted to hear of her Majesty's gracious disposition to wall their town (whereby they assure themselves of safety and quiet dwelling hereafter) that hope hath and doth procure and draw divers to resort and build here."

The town had already begun to be walled with an earthen rampart in 1574, and in 1575 the corporation agreed with Sir Henry to build a stone wall seven feet thick and sixteen feet high round a part of the town at 5s. per foot, 6d. per foot being allowed the inhabitants for the ground. The work however was not completed till 1608, when after various delays the walls were finished with a wet ditch and seven bastions. Meanwhile the Mac Donnells had again assailed the town, and Sir John Chichester, the governor, sallied out 4th November, 1597, to repel the attack of James Mac Sorley, fell into an ambuscade and was put to death by the enemy. The plantation of Ulster and the settlement of Sir Archer Chichester's colony in the S. of Antrim, and of Sir Hugh Montgomery's on the opposite coast of Down, now relieved the inhabitants of Carrickfergus from the more immediate dangers of a hostile neighbourhood, but in the wars consequent on the rebellion of 1641 they had again their full share of the troubles of the times. The castle was first occupied by Munroe (15th April, 1642) on behalf of the Scottish Presbyterians; next (1646) by Monk for the parliament; next (1649) by Montgomery, Lord Ardes, for the king; next (1688) by Lord Iveagh, for James II.; and finally, after being obstinately defended by Colonels Mac Carthy More and Cornac O'Neill, and two regiments of Irish Catholics, it surrendered, August 29, 1689, to Duke Schomberg, commanding the army of William III. On Saturday, June 14th, 1690, King William landed here in person, and immediately proceeded S. on that important campaign which decided the future prospects of both countries at the Boyne. On the 21st February, 1760, Commodore Thourot arrived in the

bay with one 44-gun frigate and two sloops of war, and having disembarked about 800 men, attacked the town, which, together with the castle, he carried after a smart action the same day. Five days after, the French forces re-embarked, after forcing a supply of victuals and amputation from Belfast, and were captured on the 28th off the Isle of Man, after a severe action with Commodore Elliot, in which Thourot was killed and 300 of his men killed and wounded. The last scene of violence connected with the history of this veteran fort was the capture of the Drake, a British sloop of war, in the roads opposite the town, by Paul Jones, in the Ranger, an American vessel, on the 24th of April, 1778.

Of the antiquities of Carrickfergus the castle is the most interesting. It stands on a rocky peninsula jutting into the sea on the south-eastern side of the town. This rock, from which the town takes its name (meaning the rock of Fergus, an Irish king of that name, drowned there in pagan times), rises gradually to an elevation of about 30 feet towards the sea, and is entirely occupied by the works of the fortress, consisting of a double ballium or upper and lower yard, with batteries mounting about 25 pieces of cannon and two ancient half moons protecting the entrance on the land side. In the upper yard stands the keep, a square tower 90 feet high, formerly entered by an arched doorway in the second story. It has been latterly used as an armoury. The court house and gaol occupy the site of a Franciscan monastery, founded here in 1232 by the famous De Lacy, who was buried within these precincts in 1264. On the dissolution of monasteries, the friary, after serving for various civil purposes, came into the possession of Sir Archer Chichester, who built (1610) on the east side of the ruins a splendid house named Joymount after the lord deputy Mountjoy. Joymount afterwards fell to decay, and the plot of ground has ultimately been occupied as above stated. Half a mile W. of the town is the site of the priory of Woodburne or Goodburne, on the banks of the Woodburne river, which has here some pretty falls. The sites of two hospitals are also pointed out as well as of several of the small castles of the early inhabitants. Numerous maps and plans of Carrickfergus as it stood in the reigns of Elizabeth and James are extant, in which these castles appear surrounded by the straw and mud huts of the poorer classes, and each protected by its separate fortifications. Part of the town wall and one of the gates are still standing.

The appearance of the town is respectable, the houses being generally of stone and slated. There are several good streets, of which the chief or high street is terminated by the county gaol and court-house, founded 1799, and built at an expense of 21,785l. 6s. 4d. The gaol is calculated for 240 prisoners. The market-house at the opposite end, where the main street diverges, one branch leading to the quays and castle, and another to the road to Belfast, is a respectable building, built 1755. The parish church of Saint Nicholas is situated on a rising ground on the southern side of the town: its date unknown, but it is of great antiquity, and is a building of considerable size and dignity. The chancel window, presented to the parish by Mr. Burrell in 1800, is of stained glass, and represents St. John baptizing Christ in the river Jordan. The church is cruciform; the old steeple at the west end of the building was taken down in 1778, and the present handsome spire erected in its place by subscription. A small pier projects from the southern extremity of the rock on which the castle is built, and encloses a dock where vessels of 100 tons can lie at the quay. The custom-house is adjoining: the customs, arising chiefly from a duty on coals, do not pay more than half of the expenses of their collection. The town is not lighted, and water is procured by pumps. There is no poor house or hospital; but a mendicancy institution lately organised is understood to be succeeding well.

The governing charter of Carrickfergus bears date 11th James I., A.D. 1612. The corporation consists of a mayor, alderman, and burgesses, with recorder, two coroners, and town-clerk. The mayor is by his office admiral of the coast from Fairhead in Antrim to Bangor in Down, and formerly a third part of all customs within the same limits belonged to the corporation; this monopoly was purchased by the earl of Strafford for 3000l. in the year 1637, and materially affected the future trade of the place. This county is distinct from the county of Antrim, and had till lately its own gaol and court-house; but these being now gone to decay

the assizes for the county of the town are held in the county court-house. The mayor and recorder sit at the quarter-sessions with the county magistrates. Carrickfergus formerly returned two members to the Irish parliament, and now returns one member to the imperial parliament; the constituency is 732. A committee of the House of Commons, July, 1833, reported that the preceding election for the borough of Carrickfergus had been marked by gross bribery and corruption among the freemen who at present constitute the majority of the electors.

The cotton trade was at one time carried on with vigour here, but it has latterly declined. A pretty brisk trade is now carried on in tanning, brewing, and distilling; but Carrickfergus is far from being a commercial place. A place and oyster fishery in the bay gives employment to a considerable number of the inhabitants. In 1823 there were 300 persons employed in various ways by this fishery. The oysters taken here are peculiarly large; the average weight is about 1 lb. 4 oz., and the measure about five inches in length and four in breadth: some have been taken that weighed 2 lbs.; their price has varied at different times from 4s. to 18s. per hundred.

In 1813 the inhabitants in the county of the town were in number 6225; in 1821 they were 8030; and in 1831 they were 8706. In 1834 their religious distinctions were, members of the Established Church, 1387; Roman Catholics, 974; Presbyterians, 6146; and Protestant dissenters of other denominations, 353: being for their numbers the most Protestant town community in Ireland. In 1821 there were in the county of the town 25 schools, educating 427 males and 343 females; and in 1834 there were 9 schools, educating 415 males and 204 females. In 1813 the schools were in number 19, four of which were kept by Roman Catholics.

(McSkimmin's *History and Antiquities of Carrickfergus*, 8vo Belfast, 1823; *Publications of the Record Commission for Ireland; Parliamentary Reports and Papers*.)

CARRIER, one who for hire undertakes the conveyance of goods or persons for any one who employs him. In a legal sense it extends not only to those who convey goods by land, but also to the owners and masters of ships, mail-contractors, and even to wharfingers who undertake to convey goods for hire from their wharfs to the vessel in their own lighters, but not to mere hackney coachmen. As the law has on the one hand thrown great liabilities on those who undertake the business of a common carrier, so it has on the other hand made many provisions for their benefit, in order to protect them from fraud and imposition.

I. *The liability and duties of proprietors of stage coaches carrying passengers*.—These, as well as the hackney coaches of towns other than the metropolis, are regulated by the statute 2 & 3 Will. IV. c. 120. In order that the public may be enabled to look for redress to responsible parties, that act provides (sec. 2) that all stage coaches shall be licensed, and a numbered plate fixed on each. The licence specifies the name and place of abode of each proprietor, the names of the extreme places between which the coach is authorized to ply, the days of its journeys, and also the number of passengers it is authorized to carry; and any person may procure a copy of this licence at the office, where it is granted by paying one shilling. A notice of the route, names of proprietors, and the licensed number of passengers, must be fixed on a conspicuous part of the coach, and a penalty of 5*l.* is imposed upon every proprietor, and also upon the driver, in case more passengers are carried than are specified in the licence. The act (sec. 37) also prohibits any outside passengers whatever, or any luggage from being carried on the roof of any coach, which is of a greater height from the ground than 8 feet 4 inches; or the bearing (that is, the breadth) of which, on the ground, is less than 1 foot 6 inches from the centre of the track of the right or off wheel to the centre of the track of the left or near wheel. The following are the limitations provided by the act for the number of passengers:—

Four-wheeled coach, drawn by four horses, and not more than 8 feet 9 inches in height, and bearing on the ground (measured as before) not less than 4 feet 6 inches—10 passengers outside, exclusive of the driver and guard.

When drawn by two or three horses only, and licensed to carry not less than 4 inside passengers—6 outside.

When licensed to carry not less than 6 inside passengers—7 outside.

Not more than one outside passenger is to sit on the box with the driver; nor more than three in front; and the same number on the back of the roof; and the remainder are to be placed on some safe and convenient place in the hind part of the carriage. An additional passenger is allowed (sec. 40) on each of the seats on the roof, provided they are respectively 5 feet long, and the extreme height of the luggage be not more than 9 feet 9 inches from the ground; and two additional outside passengers are also allowed on the boot, if its height be not more than 6 feet from the ground. In case of neglect of any of these provisions, a penalty is imposed on the driver of 5*l.* The part allotted to the luggage must be distinctly separated from the other part of the coach, by a railing or otherwise; and the height of the luggage from the ground must not exceed 10 feet 9 inches in coaches drawn by four or more horses; nor 10 feet 3 inches in coaches drawn by two or three horses. In case any person sits or is carried upon the space allotted to the luggage, both he and the driver are liable to a penalty of 5*l.*

Any passenger travelling by a coach, and also justices, road-surveyors, toll collectors, and constables, may require the driver or proprietor to allow the luggage to be measured, and the number of passengers to be counted; and any passenger may demand of the driver to stop at a toll-gate, and may require the toll-gate keeper to measure the luggage and count the passengers, and to sign a memorandum in writing of the result, which is to be delivered to the passenger, &c. and penalties of 5*l.* are imposed both on the driver and toll-gate keeper for refusal (sec. 45). A penalty of 5*l.* is also imposed on any driver quitting the box before a proper person shall stand at the head of the horses; or permitting any other person to drive; or quitting the box without reasonable occasion; or concealing or misplacing the plates; or discharging fire-arms unnecessarily; or neglecting to take care of the luggage; or asking more than the proper fare; or assaulting or using abusive language to any passenger, or person accompanying or attending upon any passenger, in coming or going to the coach (sec. 47); or endangering passengers or property by intoxication or negligence, or by wanton and furious driving or other misconduct. And the owners or proprietors are liable to the penalties where the guard or driver is not known or cannot be found.

Besides the regulations of the above statute, a coach-proprietor is bound by law to take care that his coach, harness, and horses are *roadworthy*, that is, sufficiently secure to perform the journeys he undertakes; and he will be liable to make compensation to any person injured in consequence of any insufficiency in this respect. A breaking down of the coach, and an accident happening to a passenger, are sufficient to entitle him *prima facie* to claim compensation against the proprietors, and the burden of proof is then thrown upon them to show that the injury was the result of an *inevitable* accident, and that the goodness of their vehicle and the skill or care of their driver were unimpeachable, in which case they would not be liable.

Proprietors are not liable for the result of an *inevitable accident*, such as the horses being frightened by thunder and lightning; but if the accident be not *inevitable*, it is no excuse for the driver to allege that he kept on the right side of the road if he could have avoided the danger by crossing to the other side; nor is it, on the other hand, proof of the negligence of the driver that the accident happened whilst he was on the wrong side of the road, provided no other vehicle was passing at the time.

II. *The liability of carriers as respects the conveyance of goods*.—Carriers of goods are subjected to a greater degree of responsibility than mere bailers for hire—[**BAILMENT**];—and that responsibility is much more extensive than it is in the case of injuries to passengers. By the ancient custom of the realm (which is part of the common law of this country) a common carrier of goods for hire is not only bound to take goods tendered to him, if he have room in his conveyance, and he is informed of their quality and value, but he is in the same situation as one who absolutely insures their safety, even against *inevitable accident*; he is therefore liable for their loss, though he be robbed of them by a force which he could not resist, on the principle that he might otherwise contrive purposely to be robbed of, or to lose the goods, and himself to share the spoil. There are however three exceptions to this extensive liability, 1st, loss arising from the

aggression of the king's *public enemies*; 2d, loss arising from the act of God, such as storm, lightning, or tempest; loss arising from the owner's own fault, as by imperfect interior packing, which the carrier could not perceive or remedy.

As property of large value may be compressed into a small space and transmitted by carriers, they have in modern times endeavoured, by means of notices, to lessen the extensive charge that the common law cast upon them. The notice they were in the habit of giving usually stated in substance that the carrier would not be responsible for goods above a certain value (generally 5*l.*), unless entered and paid for accordingly. After repeated discussions on the effect of these notices in courts of justice, the carriers succeeded in establishing, that they would not be liable in the above circumstances, if they could *prove* explicitly, in each instance, full knowledge on the part of the person sending the goods, or his agent, of this specific qualification of their general liability. But proof of this fact was in all cases most difficult to adduce, and to obviate this hardship the statute 11 Geo. IV. and 1 Will. IV., c. 68, was passed, by which it is enacted that no common carrier by *land* shall be liable for the loss of, or injury to, certain articles, particularly enumerated in the act, contained in any package which shall have been delivered, either to be carried for hire, or to accompany a passenger, when the value of such article shall exceed the sum of 10*l.*, unless, at the time of the delivery of the package to the carrier, the value and nature of such article shall have been explicitly declared. In such case the carrier may demand an increased rate of charge, a table of which increased rates must be affixed in legible characters in some public and conspicuous part of the receiving office; and all persons sending goods are bound by a notice thus affixed, without further proof of the same having come to their knowledge.

The Carrier's Act applies only to carriers by *land*, and the liability of carriers by *sea* is the common law liability before explained, slightly modified by two statutes; the first of which (7 Geo. II., c. 19) being found inadequate, the 26 Geo. III., c. 86, was passed, by which the liability of owners of vessels for any loss by reason of any robbery or embezzlement, whether by the crew or by strangers, without the privity of the owners, is limited to the value of the vessel and freight. They are also exempted from loss by fire, and from being liable for the loss of gold, silver, diamonds, watches, jewels, or precious stones, by reason of their being secreted or embezzled, unless the owner of the goods insert in his bill of lading, or declare in writing to the master or owner of the vessel, the nature, quality, and value of such articles respectively.

Subject to these exceptions, and also to any special contract that may have been made by a bill of lading or otherwise, a sea-carrier will be liable for all losses, except those occasioned by the act of God, the king's enemies, or the default of the party sending the goods, and he will be liable to losses occasioned by the first, if, by unnecessarily deviating from his direct course, he encounter the danger.

Lien of Carriers.—Upon the general principle that persons who, at the request of their owners, bestow money or labour on goods can detain them until those charges are paid, a carrier can refuse to deliver up goods, which have come into his possession as a carrier, until his reasonable charges for the carriage are paid. This in law is called a *particular lien*, in contradiction to a *general lien*, which is a right of retaining goods for the balance of a general account; the latter privilege is possessed by wharfingers and attorneys, but not by carriers.

(Sir W. Jones on *Bailments*; Selwyn's *Nisi Prius*, title *Carrier*; and Chitty on *Contracts not under seal*, title *Carrier*.)

CARRON, a village in the county of Stirling and parish of Larbert, where extensive iron-works were erected in 1767, by a company chartered for that purpose. Carron is situated on the river Larbert, which flows into the Frith of Forth, and is navigable. The village has also the advantage of being not far from the Clyde Canal, which, passing from Edinburgh to Glasgow, communicates with the sea both on the eastern and western coasts. Coal and iron ore abound in the vicinity of the works. In the 'Statistical Account of Scotland,' published in 1792, some details are given respecting the Carron works at that time. There were then about 1000 workmen employed, 320 of whom belonged

to a benefit society formed under the auspices of the company. The number of carts for conveying coal and iron ore was 150; the daily consumption of coal amounted to 136 tons; there were five blast-furnaces; sixteen air-furnaces; three cupola-furnaces; four mills for boring ordnance; forges for making bar and sheet iron, anchors, anvils, and a variety of articles; and a mill for grinding clay for fire-bricks. There was one steam-engine which consumed 16 tons of coal in twenty-four hours, and is described as raising $4\frac{1}{2}$ tons of water at a single stroke, and on an average performing seven strokes in a minute. In 1755, the population of the parish was 1864; in 1790, it amounted to 4000; in 1821, to 3491; in 1831, to 4248. For a great number of years the business at the Carron works exceeded that of any similar establishment in Scotland; but others have latterly rivalled, and even surpassed these works in the quantity of iron manufactured. In 1834-5, 8000 tons of iron were made at the Carron works in five furnaces. During the same period the Clyde works and the Calder works, which each possess four furnaces, produced 24,000 tons of iron. At one of these places an additional furnace has since been erected. The early adoption of Neilson's patent hot-blast has given this superiority to the works above mentioned. At the works of Gartsherrie, where it is in use, 9000 tons of iron were made in one year in three furnaces. The sum of 1*s.* per ton is paid by way of licence on each ton of iron made in the furnaces fitted up on Mr. Neilson's principle. In June, 1835, the Carron Company had only one furnace out of five in which this improvement was in operation. In the 'New Statistical Account of Scotland,' it is stated that before the introduction of Mr. Neilson's plan, 8 tons of coal and 15 cwt. of limestone were employed in the manufacture of each ton of iron; and that since 1833, when the hot blast first came into practice, each ton of iron is made with only 3 tons of coal and 8 cwt. of limestone. A saving of more than three-sevenths is effected in fuel in every ton of pig-iron made; coal instead of coke may be used; and with this great saving the iron is of better quality than when the manufacture cost so much more. The price of the best coal for making iron is 4*s.* per ton in Scotland.

CARRONADES are short iron guns differing from other guns, and from howitzers, only in their dimensions and in the manner of attaching them to their carriages; which is by a joint and bolt underneath the piece, instead of trunnions. They derive their name from the village of Carron, in Stirlingshire, where they were first made.

When fired at point blank, their range is about 150 yards; and, at an elevation of 3 degrees, it varies from 600 to 750 yards; this is much inferior to the range of a long gun, but as they throw shells and heavy shot with great effect within the above limits, they are extremely serviceable on land for breaching ramparts of earth, or for enfilading the faces of works; and at sea, in engagements at close quarters. A small extension of the chase surrounds the muzzle, in order to protect the sides and rigging of the ship from the effects of the explosion.

For the dimensions and weights of carronades, see Spearman's 'British Gunner.'

CARROT (in horticulture), the fleshy root of the *Daucus carota*. This kind of esculent is too well known to require any description. For garden purposes there are three principal varieties; namely, the early horn carrot, a small kind used for the earliest crops; the long orange, or Altringham carrot, a very large kind, for ordinary summer and winter use; and the purple carrot, a French sort, remarkable for its deep purple colour and unusual sweetness. The latter is not so much known as it deserves to be; the two others are in common use. Several others, among which is a white kind, are mentioned in seedsmen's lists, but they are of little importance.

Nothing can be easier of cultivation than the carrot, provided the soil is light and free from stones; in stiff or rocky soils it is not worth the expense of growing. The seeds are sown at intervals, from the end of February till the beginning of August; they are lightly raked into the soil, having been previously pressed down with the feet. Some persons mix them with dry sand previously to sowing, in order to separate them from each other, and to render them less liable to be blown about by the wind in consequence of their lightness. When they have come up they require no further care than to be hoed to the distance of about six inches apart, and to be kept free from weeds.

The wild carrot is common on sandy land in England, but its roots are tough and dry, and unfit for food.

CARROT (in agriculture). The large orange carrots, which are the most common for winter provision, are chiefly raised in the fields; and when they can be conveyed to large towns for sale, they are a very profitable crop on light and deep soils. The principal use of carrots is as food for cattle. The orange carrot and its varieties are the most common in England, but the large white and yellow carrots are more esteemed on the continent; they are supposed to contain more saccharine matter, and to produce a greater bulk of nutriment on the same ground. The white carrot also will grow on heavier soils than the orange, and may be sown in spring amongst barley, in the same manner as clover usually is; with this difference, that the roots are taken up before winter, and the land may be sown with winter corn the same year. This is commonly practised in Belgium. The barley amongst which the white carrots are sown is chiefly winter barley, which is reaped early. As soon as the barley is cut, the land is well harrowed to pull up the stubble, the weeds are carefully taken out, and liquid manure is poured abundantly over the surface. The carrots, which were scarcely visible, and of which the tops were cut off in reaping the barley, now shoot rapidly, and where they grow too thick are thinned out by hoeing. By the end of autumn a good crop of carrots is obtained; and if they are carefully forked up, the ground may be sown with rye without any other preparation.

When carrots are cultivated in a regular rotation as a principal crop, they are sown in March on land which has been ploughed to a considerable depth before winter, and has had the benefit of the winter's frost. It is not usual to manure the land, but it is best to sow carrots on land which has been abundantly manured for the preceding crop. If it be thought necessary to improve the land by manure, it must be done with well-rotten dung, which should be ploughed in very deep. Without this precaution the carrots will be apt to *fork*, as it is called; the root being divided will not swell regularly, and instead of being of a fleshy consistence will become fibrous and hard. The best mode of cultivation is to have the land in a moderately rich state and thoroughly pulverized; to sow the seed in drills, at the distance of a foot or more from row to row; to cover it slightly, and as the plants appear, to water them with diluted urine or the drainings of dung-hills; to destroy all weeds carefully by the hand and the hoe, and to thin the plants in the rows to the distance of 5 or 6 inches or more, according to the richness and depth of the soil. Although the carrot, when it grows most vigorously, does not throw out any considerable fibres from the upper part of the root, and appears to draw its chief nourishment from its lower end, yet it is a great advantage to keep the ground stirred and light between the rows; for exceedingly minute horizontal fibres shoot out to a considerable distance from the sides of the root, and tend much to increase its size. The seed of the carrot has numerous hooked hairs which spring from the husk, and make the seeds adhere together; on this account carrot seed is usually mixed with earth or sand, and well rubbed in the hand before it is sown. Two pounds of seed are sufficient for an acre if the seed is drilled; it requires double the quantity if sown broad-cast. In this last way very heavy crops are sometimes obtained, but the expense of weeding the carrots by hand is so great that the drilled crops, besides being more certain, are more profitable. Seed which is two or three years old will vegetate, and it is more essential that it should be ripe and heavy than new. Too much care cannot be taken in selecting good seed. The finest and largest carrots should alone be chosen to plant out in spring to produce seed. They will throw out vigorous stems bearing numerous umbels, which, as the florets fade and the seeds ripen, contract into the form of a bird's nest. Those who are curious in the choice of the seed take only such seeds as grow on the outer border of the umbel. The tops of the carrots are frequently cut off before they arrive at the full size, as food for cattle and sheep, who are very fond of it; but this is not a judicious plan; as the loss in the growth of the roots from being deprived of the leaves is much greater than the value of the tops as food, especially if they are cut off repeatedly, which is sometimes done when fodder is scarce. When the plants begin to wither, and the outer leaves to droop to the ground, the tops may be safely mown, and the roots left in the ground. They have then acquired their full growth, and will remain

sound in the earth till there is danger from the winter's frost.

The best method of taking up the carrots to store them for winter use is by means of three-pronged forks, such as are used in digging asparagus beds. They should be rather blunt at the point and sides of the prongs, and be stuck into the ground vertically by the side of the rows; by pressing down the handle the carrots come up without injury. The plough is sometimes used after the coulters has been removed; but with all the care of the ploughman, the plough and the horses will cut and bruise many of the finest carrots. Carrots may be kept all winter in dry cellars, if they are protected against the frost. The more common way is to store them with straw in long trenches, like beet. [Next.] The produce of carrots on good light land is nearly double that of potatoes, and they do not impoverish the land so much. From twenty to forty pounds of carrots, with a small quantity of oats, is a sufficient allowance for a hard-working horse for twenty-four hours. Where hay is scarce, it is a most economical substitute; and where the value of urine is known, carrots are much prized, as they greatly tend to its increase.

In Brittany they have an ingenious method of getting several acres of land trenched by the plough and the spade at the same time, for the growth of parsnips and carrots. The different farmers join to bring as many labourers together as will dig out a furrow as rapidly as the plough can draw it: they divide the whole length of the field equally among them. As soon as the plough has made a furrow, the men trench the bottom of it with their spades nine or ten inches deep, throwing the earth over the furrow slice last turned; on the return of the plough the next slice is turned into the deep trench and immediately covered by the spades as before. Thus an acre is readily trenched in one day to the depth of fifteen or eighteen inches, and all the weeds are buried: carrot or parsnip seed is sown on the surface and slightly harrowed in. The common mode of ploughing in stiches is the most convenient for this operation, as each man will only have to move from one side of the stich to the other immediately after the plough has passed. But a second plough following in the furrow made by the first will do the work equally well, and at less expense.

If carrots are cut in pieces and steamed, they become more nutritious, and the expressed juice made to ferment affords by distillation a very good and wholesome spirit. Sugar may also be extracted; but the carrot is inferior to the beet in this respect.

CARSTENS, ASMUS JACOB, a distinguished German artist, no less remarkable for his enthusiastic perseverance, than for his singular mode of study, and the peculiar bent as well as force of genius, was born at St. Jürgen, near Schleswig, May 10th, 1754. His father was a miller, in no more than decent circumstances; but his mother, who was the daughter of an advocate at Schleswig, had been exceedingly well-educated, and was therefore able to bring up her three sons in a manner very superior to what the circumstances of the family would otherwise have allowed.

After his father's death, which happened when he was about nine years old, Asmus was sent to the public school at Schleswig, where he made little or no progress; but in the cathedral, which soon became his daily haunt, he had an opportunity of examining the pictures there, by Jurian Ovens, a pupil of Rembrandt, and on these, to him miracles of the pencil, he would gaze in boyish ecstasy day after day, with unabated admiration. To be able to achieve such works appeared to him the noblest object of human ambition. His mother readily seconded his inclination, and on his quitting school at the age of sixteen, applied to a painter named Geeve to take him as a pupil; but the sum demanded was much greater than could prudently be afforded. A second application of the same kind was then made to Tischbein, of Cassel, an artist of great reputation in his day, but with no better success.

His mother soon after died, and the guardians of the children and of their little property, obstinately refusing to listen to Asmus's earnest entreaties, placed him with a wine-merchant at Eckernförde. With a kind of hopeless resignation, he at first determined to dismiss all his former aspirations after art, and to apply himself to his new duties; but those aspirations soon revived again in all their force, and he employed the whole of his leisure time, and frequently a considerable portion of the night, in drawing. Fortunately

his master did not oppose pursuits which he thought might keep him from worse amusements. About this time, too, Carstens renewed his acquaintance with Ipsen, a young painter whom he had known at Schleswig, from whose instructions he obtained some insight into the management of colours and other technical matters. He likewise attentively studied whatever books he could procure relative to art; among others, Webb on Painting, to which he owed himself principally indebted for correct and worthy notions respecting it. Having served five years, he purchased out the remaining two of his apprenticeship, and proceeded to Copenhagen, where he again met with Ipsen, who procured for him free access to the Royal Gallery of Paintings, and to the collection of casts and antiques at the academy. These latter more particularly attracted him, and he was assiduous in studying them; not however by making any drawings from them, but merely by examining them again and again from every possible point of view, so as to impress them, even in all their minutiae, ineffaceably upon his memory; owing to which process, he was, according to his own assertion, able at any time to recall their perfect images before him. Whilst he was thus daily acquiring a fund of real knowledge in his art, although making no very visible progress in it, and in fact hardly exercising himself with his pencil beyond one or two essays at composition, his finances rapidly decreased; he therefore endeavoured to support himself by taking likenesses in red chalk, and was so fortunate as to be thus enabled to continue his usual studies for two years longer, during which he produced his 'Bilder's Death' and 'Æolus and Ulysses,' compositions that excited much notice, and would have obtained for him admittance into the academy, had he not given offence on a particular occasion. But having thus closed against himself the road to favour, he determined upon leaving Copenhagen and going to Rome along with his youngest brother (who had also been studying painting at Schleswig) and the sculptor Busch. Accordingly, they set out in the spring of 1783, and Carstens and his brother travelled on foot as far as Mantua, their companion having parted from them at Nuremberg. After passing an entire month at Mantua, where he was filled with admiration of Giulio Romano's works, Carstens found that they must abandon their plan and return homewards. They accordingly set out, again northward, passing through Switzerland, and stopping for a short time at Zurich, where Gesner assisted Carstens in disposing of his drawings; and with the sum thus opportunely raised, the brothers were enabled to reach Lübeck. Here he was glad to take up with his former occupation of portrait-painting, which he pursued for nearly five years; but he employed all the time not so occupied in making historical and poetical compositions. He also now began for the first time to read diligently all the best translations of the ancient poets, and those of Ossian and Shakspeare; and in this course of study he was greatly benefited by the advice and literary taste of his friend and biographer Fernow, with whom he happened about this time to become acquainted. The course of reading he had taken up expanded his mind and quickened his imagination, and the fruits of it shortly began to manifest themselves in a number of compositions from Homer, the Greek tragedians, and other great masters of poetry, both ancient and modern. With his exceedingly moderate desires, confined to the mere necessities of life, Carstens might, as far as worldly advancement was concerned, have been content with his situation at Lübeck, and even have accounted himself rich in the intellectual enjoyments at his command, had he not felt that, so long as he continued there, he was in a state of exile, and cut off from the hope of being able to produce any works of magnitude; gratefully therefore did he accept the generous offer of Rodde, a wealthy amateur, who furnished him with the means of visiting Berlin.

In that capital he had at first to contend with many difficulties, for he had resolved to practise portrait-painting no longer, but to occupy himself entirely with historical subjects. But opportunities not presenting themselves, after a time he became reduced to the greatest straits, and was obliged to make designs for book-prints. At length, his 'Fall of the Angels,' a large composition containing upwards of 200 figures, obtained for him an appointment as one of the professors at the academy, and the following year a considerable gratuity was added to his salary. His pressing difficulties would not allow him to reject this piece of good fortune; otherwise he might have hesitated to accept it; but he regarded it chiefly as the means of obtaining a

travelling pension to Rome, which he was now more than ever desirous of visiting. He had become acquainted with the architect Genelli, who was then just returned from Italy; and what he learned from him served only to increase his desire. Fortunately, at the recommendation of Genelli, he was employed to decorate the walls of a saloon in the Dörville palace with a series of mythological subjects. When the work was completed, it was viewed by the king, to whom Carstens was introduced as the artist, by the minister von Heimitz, the proprietor of the mansion. This interview at once obtained for him the promise of a travelling pension, and in the summer of 1792 he again set out for Rome. He travelled through Dresden and Nuremberg, making some stay at the first place for the purpose of visiting the Gallery of Antiques and that of pictures; and at the latter, in order to become acquainted with the works of Albert Dürer, whom, after Michael Angelo and Raphael, he held to be one of the greatest masters in his art. He did not, on the contrary, estimate very highly what he had beheld at Dresden, and was greatly disappointed in the productions of Mengs, which, in his opinion, display extraordinary talent and no genius.

Arrived at Rome, Rome for a long time existed to him only in the Vatican. His first object was to imbue himself thoroughly with the spirit of Michael Angelo and Raphael, to catch, if possible, their modes of thought, and to trace their conceptions to their source. Highly wrought up as his expectations had been, he found them here surprised, and that their works were instinct with a mental power, of which no copies or engravings had before conveyed to him any idea. Hardly could he afterwards persuade himself that he was in the same Rome which contained such consummate master-pieces, when he began to visit the studios of living artists; instead of meeting with powerful rivals or able companions in the same track he was pursuing, he found himself quite alone and insulated from those around him, both in his notions of art, and in his enthusiasm for it. Ambitious littleness, affectation, empty theatrical display, artificial colouring, and mere manual dexterity of the pencil, were in his opinion the leading characteristics of the living school. Neither did he at all attempt to disguise his opinion, or to conceal that he considered the system of study pursued to be one altogether injurious, and calculated only to bolster up imbecility. Much of the defectiveness he discerned was ascribed by him to the constant use of the model, which, he maintained, was not studying nature, but a substitute for it.

The severity of his principles of criticism obtained for him not a few enemies; and they more than insinuated that he could not perform what he exacted from others. He soon convinced them of the contrary, by a large drawing representing the visit of the Argonauts to the centaur Chiron, a subject he had before produced at Berlin, but which he now re-composed, and in a style that plainly indicated how much he had already benefited by studying Michael Angelo and Raphael.

The two years, to which his stay at Rome was limited, having expired, he begged hard for a little longer extension of the term, as he was preparing to make a public exhibition of the subjects which he had produced while in Italy. He was in fact determined if possible to establish himself in the city of the Vatican, the real academy for those who know how to avail themselves of it; and he trusted that this exhibition would enable him to do so, though his pension, as was likely, should be withdrawn. His exhibition was opened in April, 1795, and consisted of eleven subjects, mostly poetical and mythological, and few of them ever before treated. None of these compositions were oil pictures, for Carstens was aware that colouring was not his forte, and that, had he produced them as such, his enemies would have dwelt loudly upon their defects as paintings, overlooking all positive merit of a much higher kind than manual execution; he therefore wisely chose to submit them to the public in that shape which was best calculated to compel attention to the poetry of his conceptions, to the power of his imagination, the dignity and simple grandeur of his style.

The result proved his foresight: both in style and subject these works were an earnest of powers as superior as they were uncommon; and the artist's fame was soon spread through Germany by an article on the exhibition, in Wieland's 'Mercur.' The same year he sent three compositions to Berlin, whereupon he was again urged to return to his post in the academy; but instead of its being complied with, this demand was followed by remonstrance and re-

fusal on the part of Carstens. The consequence was that he cast off his dependence on the Berlin academy altogether. In the course of the two following years he produced many fine compositions, including a series of twenty-four subjects from Pindar, Orpheus, and Apollonius Rhodius, all of them illustrative of the Argonautic expedition. This series it was his intention to etch himself, but in the autumn of 1797 he was attacked by a serious malady, which was succeeded by a slow fever and an obstinate cough, whereby he was so enfeebled that he was unable to employ his pencil except for a very short interval in the day. Yet even after he was incapable of quitting his bed, his wonted enthusiasm and energy did not forsake him; and but a few hours before his death he conversed with his friend Fernow respecting a mythological subject which had suggested itself to him. He expired on the 25th of May, 1798, when he had just entered his forty-fifth year.

Thus may Carstens be said to have been prematurely cut off just as he had begun his career as an artist, for it can hardly be dated earlier than the time of his visiting Rome, which was not until he had reached the age of thirty-eight. Up to that period, all that he had been able to do was little more than to acquire preparatory knowledge, and that under such unfavourable and disheartening circumstances, attended with so many interruptions and obstacles, that nothing short of almost unexampled enthusiasm could have enabled him to surmount them. To art he gave himself undividedly; his whole soul was in it, so that although he had not mastered some things that lie more on the surface, he had dived into its depths and recesses. His originally defective education only stimulated him to greater self-exertion, and to cut out for himself a way through the barriers that opposed his progress. At the same time, much that seemed against him was in reality in his favour; his utter seclusion from general society and its interests preserved to him a generous simplicity and elevation of mind which effectually secured him from the artificial and conventional, and caused him to entertain those lofty ideas of art which, if they do not always inspire, ennoble inspiration where it exists. Specious cleverness, bravura of style, external showiness of composition, and the plausible mastery of execution, could not impose upon or satisfy him, if higher intellectual qualities were wanting. He considered that by far too much stress was generally laid upon the mere accomplishments of his art, and that the attention paid to the mechanical part of it had been one great cause of its declension. What he chiefly valued was creative power, intelligence, and mind, of which he regarded external forms merely as the expression. Conformably with such opinions and theory was his own practice. His compositions, which he was in the habit of completely shaping out, maturing, and finishing up mentally, before he committed them to paper, are all marked by a severe simplicity and fine poetic conception; and had a longer life and health been granted to him he would doubtless have left behind him works commensurate in other respects with their intellectual value, and which would have acquired for him universal fame. Admirable and even wonderful as his productions are in themselves, they being chiefly drawings, it is not very surprising that they should be comparatively little known, since only few can have the opportunity of inspecting them, and fewer still of thoroughly studying them as they deserve; whereas had the same compositions been given to the world as pictures on the usual scale of historical painting, they would have enjoyed extended celebrity, and placed the name of Carstens almost next to those of the two great masters whom he strove to emulate.

CART. The drag-cart without wheels, which is used in some mountainous districts, is one of the simplest contrivances for transporting heavy weights. It consists of two strong poles, from twelve to fifteen feet long, connected by cross pieces fixed at right angles to them, by morticing or pinning, so that the poles may be two or three feet apart. About eighteen inches of the poles project beyond the lowest cross piece, the ends resting on the ground. The other ends of the poles form the shafts for the horse to draw by. The load is placed on the cross pieces, over which boards are sometimes nailed, for the purpose of carrying stones, or such things as might fall through between the cross bars; it then resembles the body of a cart taken off the wheels. The horse bears one end of the drag cart by a strap over his back, and drags it on by means of a common cart collar or a breast strap. This vehicle is ex-

tremely useful in steep, and rough descents, especially to draw stones from quarries, and can be made of rough poles at little or no expense. Pieces of hard wood fixed under the ends of the poles, and renewed as they wear out, will prevent the ends of the drag cart from wearing away, and will allow it to slide along more easily.

The Irish car (fig. 2) may be considered as the next step

Fig. 1.

Fig. 2.

Fig. 3.

towards a better construction. This car consists of a bed or platform and two shafts. The wheels, in the simplest form, are round disks of wood made by nailing planks two or three inches thick over each other, so that the fibres of the wood in one plank shall lie at right angles to those in the other. They are then sawn into the form of a circle, and an iron tire put on the circumference. Two of these disks are fixed on a square axle of wood at the distance of three or four feet from each other. The ends of the axle, which project three or four inches beyond the wheels, are then rounded in the form of cylinders of two or three inches diameter. To the under part of the bed of the cart two blocks of wood are fixed, which raise it so that the wheels may go under the cart, and in these blocks are two round holes to admit the ends of the axle. Two strong nails or iron pins driven obliquely into the blocks, after the wheels are put under, serve to prevent the axle from slipping out. A little grease on the ends of the axle diminishes the friction, and prevents the disagreeable grating of the wood when the wheels turn round. This is the simple old Irish car. The only difference in the construction of the most improved modern cars is the substitution of neat wheels, and iron axles for those described above, and a railing or box fixed on the platform. The great simplicity of the Irish car, its easy construction, and the convenience of the platform to place the load on, are its greatest recommendations. It is well adapted to narrow mountainous roads; and the wheels being quite under the bed, there is less danger when two cars meet, or among trees and rocks; especially when one man has the charge of several cars, or the horses are permitted to find their way home by their own sagacity. There is a considerable inconvenience in turning, as the wheels do not turn separately, and one of them must be dragged along, while the other forms the centre round which the car turns. In the improved jaunting cars, the wheels are made to turn separately on the axles, by which this inconvenience is obviated. The wheels of the carriages on railroads are constructed on the principle of those of the Irish car. The axle turns with the wheels in a bush or box fixed to the carriage. This gives greater facility for keeping a constant supply of oil to the box by means of a fixed reservoir; and the carriage not being required to turn round, no inconvenience arises.

The common cart differs from the car in that the body rests on a fixed axle between the wheels, which turn upon the axle by means of boxes in the centre of the nave. The simplest cart is that used by carriers in France and Germany. (Figs. 1 and 3.) It consists of two strong poles of ash or beech, resembling those of the drag-cart described above, but

stronger, and fashioned with more care, so as to have considerable strength at the place where they rest on the axle-tree. One end forms the shafts, and the whole is equally poised on the axle. The wheels are often nearly six feet in diameter, and narrow at the tire; they are slightly dished, but run nearly perpendicularly to the road. On these carts very great weights are transported, so as to require five or six horses to draw them. On paved roads they may have some advantages, but there is much loss of power when many horses draw at length, and the horse in the shafts is often much distressed by the weight suddenly thrown on his back, and by the striking of the shafts against his sides. It would be impossible for the shaft-horse to bear the weight in going down steep descents, or to keep his footing up steep hills (however well the cart may be poised), if it were not for an ingenious contrivance, by which the load is shifted at pleasure backwards or forwards on the axle. In ascending, the centre of gravity is moved nearer to the horse, and, in descending, farther back, so as to be always nearly perpendicularly over the axle. Another contrivance is a mode of retarding the motion of the wheels in descending. This is done by forcing a pole against the outer rim of the wheel, one end being fixed to the shafts of the cart, and the other down, by means of a rope, tightly against the side of the wheels, which rubs hard against it. The object is thus obtained, but the wheels are soon worn away, and the pole requires to be carefully looked to, because it often wears through and breaks, when the whole load comes suddenly against the horse and throws him down. Another equally rude and extremely noisy mode is to cut a tough branch, a little longer than the distance between the wheels, and place it horizontally between the spokes, so that it projects about an inch or two on each side. The wheel, in turning round, bends the branch until the ends escape from one spoke and strike the next; thus a constant retardation of the wheel takes place at the expense of the spokes, which are soon worn out. A better contrivance is a piece of wood or iron in the form of a small segment of a circle, of the same diameter as that of the wheel, which is made to press more or less on the rim of the wheels by means of a lever to which it is attached. It is regulated by a screw turned by a winch, which gives the exact pressure requisite to overcome the downward tendency of the load, and may be so nicely adjusted that it requires only a slight exertion in the horse to draw the cart down. By some of these contrivances many of the inconveniences arising from the use of carts are obviated. Where the roads are level and hard, waggons are much to be preferred to carts; but in hilly countries and bad roads, carts have many advantages.

For agricultural purposes, various kinds of carts have been invented. The capacious tumbrel for carting earth and dung, with broad wheels to prevent their sinking in soft ground, is too generally known to require description. The best constructed carts have iron axles with the ends or arms turned smooth, and very slightly conical. The boxes in the naves of the wheels, which receive the arms, are made of cast iron, and ground smooth, so as to require only a small quantity of grease or oil to make the wheels run easily, without allowing any play or side motion. It is usual to give the axle a bend at the place where it enters the wheel, by which means the planes of the wheels are made to diverge from each other and give more room for the body of the cart. But this is decidedly wrong. It is clearly proved that the draught is least when the arms are quite horizontal, and if the wheels are slightly dished, that is, if the spokes are driven into the nave obliquely so as to throw the rim a little beyond the perpendicular, the lower spokes in each wheel will slightly diverge, and give greater steadiness to the whole. When the axle is bent, the rim of a broad-wheeled cart must be slightly conical, in order that it may rest flat on the ground; and it is easily proved that in this case the cart is dragged on the road at every revolution, along a space equal to the difference between the greater and lesser circumference of the rim of the wheel, giving unnecessary work to the horses, and greatly injuring the roads. The light Scotch cart, drawn by one horse, is justly considered as the most advantageous for transporting earth, lime, or dung, especially in hilly countries. It is low and short, so that the horse draws very near the centre of gravity; and there is little power lost by obliquity. The loads may be so adjusted as to bear more or less on the horse, according to the declivity; and experience has proved that more weight can be transported by a given number of

horses, when each is attached to a single Scotch cart, than when three or four draw together, except it be on very level and hard roads, or when the horses move at a quick pace. The objection made to single-horse carts, that each requires a man to drive it, is obviated in Scotland, where the horses are trained to follow each other, and one man can attend to several carts and horses. In England this is not allowed on the roads for fear of accidents.

The Scotch cart is made to carry hay and straw by means of a light frame, which is laid on it, and projects over the body and the wheels in every direction. At harvest it is found to collect the sheaves of corn and carry them to the stack or barn more rapidly than could be done by a waggon. A good horse will walk faster, when he has a load on his back, than he could do if he were merely drawing; and although this exertion, if continued long, would exhaust him, he soon recovers his breath, if he has only been urged for a small distance, and then returns with a light empty cart.

To avoid the weight resting on the back of the horse, carts have been invented with three wheels, the small additional wheel being made to turn in front. It is only in the case of moving earth down a declivity, and returning with the empty cart, that it has any advantage over the two-wheeled cart; it is therefore seldom used for general purposes. The additional wheel adds to the weight which the horse has to draw, and is an incumbrance in a ploughed field.

The addition of springs to carts and waggons is a very great improvement, and should be adopted in every case where they are much used on the roads. The additional weight of the springs and their cost are greatly overbalanced by their advantage: they lessen the draught, and, by preventing jolting and shaking, add to the durability of the vehicles. Where a light active kind of horse is used which can trot with a moderate load, it will be found that there is a great advantage in occasionally increasing the pace at which empty carts and waggons are made to move. In Holland and Flanders, the waggons are always driven at a smart trot when going empty to the field in harvest or hay-making, and much valuable time is saved by this means.

CARTAGENA, CARTHAGO NOVA of the ancients, a seaport town on the Mediterranean, in the province of Murcia in Spain, in $37^{\circ} 36' N.$ lat., and $1^{\circ} W.$ long. It is said to have been built by Hasdrubal Barca, who gave it the name of New Carthage, and intended it for the metropolis of the Carthaginian possessions in Spain. The Romans after their conquest of Spain sent a colony to it, and called it Julia Nova Carthago. It now forms with its territory a partido or district of the province of Murcia, and has military and political governor, and an alcalde mayor, or judge of the second class. Appeals lie before the royal chancery, or higher court of Valencia. Cartagena is one of the three naval stations of Spain: it has a royal dock-yard, a fine basin, a gun wharf, a castle, and a bagnio for the galley slaves. The harbour is large, one of the best in all Spain, and the safest of all on the East or Mediterranean coast. It has 30 feet water clear under the walls of the town. It is defended by batteries at the entrance, and by several forts and redoubts on the surrounding hills. The town is regularly built, and has some good streets and buildings, four parishes, and 29,500 inhabitants, including the suburbs. (Mifano, *Diccionario Geografico de España*.) It has been however for more than half a century past in a state of decay, owing to the political troubles and the interruption of its trade with the Spanish-American colonies. It has some manufactories of cloth for sails, of cables and ropes, and other articles for shipping. The country around produces corn, wine, oil, and barilla; in the neighbouring mountains are mines of lead, and it is believed also of silver; the latter were worked in the time of the Carthaginians and Romans, but are now abandoned. The large and curious cave called Cueva de San Juan, which abounds with rich crystals and pyrites, is believed to be one of these old mines. Cartagena is 27 m. S. by E. of Murcia, and 20 m. W. of Cabo Palos.

CARTAGENA, a seaport in the republic of New Granada, on the northern shore of South America, in $10^{\circ} 25' 48'' N.$ lat., and $75^{\circ} 30' W.$ long., about 50 miles from the mouth of the Rio Magdalena.

The harbour of Cartagena is one of the safest and most convenient in all America. It is formed by two islands extending along the coast S. and N. The most S. island, called Tierra Bomba, is about two miles long and wide, and

between it and the Cape Bara is the narrow entrance of the port called Boca Chica. The N. island is on an average hardly half a mile wide, and low, whilst Tierra Bomba rises to a moderate height. The entrance of the port is so narrow that only one vessel can enter at once, and as some sandbanks occur in it a pilot is always required. It is defended by two strong castles. The harbour itself is about six miles long; its width varies from two to four miles. It has a sufficient depth of water and good anchorage, and its surface is as little agitated as that of a river.

On the N. island and at the most N. corner of the harbour is situated the town, on a sandy tract of land. It occupies the whole width of the island, so that its N.W. walls stand on the beach of the open sea, and the S.E. on the harbour. To the E. of the town is another low island, on which the suburb, called Xiximam, stands: both are connected by a wooden bridge. Another bridge unites the suburb with the mainland.

The town is regularly built, with straight but rather narrow streets, which are still more narrowed by the projecting balconies, so that they nearly exclude the daylight, and give the town a gloomy aspect. The houses have commonly two stories, but their exterior resembles a convent, having only one or two windows towards the streets, and these generally small. These buildings include a fine open space in the middle, on which lofty and airy rooms open, and which is surrounded by a corridor. The town is well fortified, and on the land side surrounded by several fortresses; but it is commanded by a hill called Popa, which is not fortified, and which no event stands.

Among the public buildings are several fine churches and seven convents. The immense terms situated within the walls of the town are just admired by travellers, and the water preserved in them is excellent: otherwise the water is bad, which, in consequence, united to the great heat of the climate, produces frequent diseases among the lower classes. The yellow fever often makes great ravages.

The inhabitants, who amount to between 18,000 and 20,000, are mostly people of colour, descendants of Spanish and Indian women; but there are also individuals who derive their origin partly from Africans. The majority are sailors and fishermen, but many are shopkeepers and mechanics, and the latter show that in some trades they are not deficient in talent. Their jewellery and shell-works are excellent.

The commerce of this town was formerly considerable. Merchant vessels, sent from Spain, waited here till their return cargoes had arrived at Panamá, when they sailed to Puerto Bello, where they took them in, and came back to Cartagena before their return to Europe. But since the revolution in South America the commerce of this town is limited to exporting the produce of the valley of the Rio Maderal, and importing the manufactured goods which are consumed in it. The more wealthy inhabitants frequently resort to the village of Turbaco, which is about 12 miles distant, and more than 1000 feet above the level of the sea, to avoid the great heat in summer. Foreigners are attracted to this place to see the *vulcanitos*. From a swamp situated at a short distance from Turbaco, in a forest of palm-trees, rise about 20 hillocks to the height of 20 or 30 feet. They have the form of cones, and on their summit is a crater filled with water. From these craters there are eruptions at certain intervals, in which gas is evolved, and which are attended with a throwing up of muddy water. (Juan and Ullon's *Travels*: Humboldt and Mollien.)

CARTE, THOMAS, was born in April, 1686, at Clifton in Warwickshire, of which parish his father, the Rev. Samuel Carte, was vicar. He matriculated at Oxford, but took his degree of master of arts in the University of Cambridge; and afterwards entered into holy orders, and was attached to the cathedral of Bath.

Carte's opinions were very strong in favour of the Stuart family, and his zeal brought on him some suffering. On the accession of George I., he declined to take the oath of allegiance, and therefore abandoned the priesthood: in 1715 he was obliged to conceal himself lest he should be apprehended as participating in the rebellion; and in 1722 he was so strongly suspected of being concerned in the conspiracy of Bishop Atterbury (whose secretary he was), that 1000*l.* was offered for his apprehension, and he fled to France, where he resided nearly twelve years under an assumed name. Again, in 1744, he was arrested under a

like suspicion of favouring the expected descent of the Pretender. He died near Abingdon, in 1754.

So far as great labour and indefatigable research constitute an historian, Carte may lay claim to that character. His works consist of an edition of 'Thuanus,' in 7 vols. fol.; a 'Life of James, Duke of Ormonde,' in 3 vols. fol.; and 4 vols. fol., of the 'History of England,' bringing it down to the year 1654. Besides pamphlets and some minor works, he likewise published at Paris a Catalogue, in French, of the Gascon, Norman, and French Rolls, preserved in the Tower of London. His manuscripts are preserved in the Bodleian Library at Oxford.

CARTE-BLANCHE (literally, white card) is a paper signed and, if necessary, sealed by the party against whom it is to be used, but (with the exception of the signature and seal) blank; in order that it may be filled up with such conditions as the party to whom it is delivered may prescribe. Thus when Charles I. was about to be condemned, his son, Prince Charles, sent to the parliament a blank paper signed and sealed by himself, in order that they might dictate their own terms for saving his father's life.

The term is often used to express an unrestricted authority delegated by one man to another: thus a general is said to have carte-blanche from his sovereign when he has leave to carry on the warfare at his own discretion.

CARTER, ELIZABETH, was the daughter of Dr. Nicholas Carter, an eminent Latin, Greek, and Hebrew scholar, one of the six preachers in Canterbury Cathedral, and perpetual curate of Deal in Kent, where his daughter Elizabeth was born December 16, 1717. Her mother, a Dorsetshire heiress, of the name of Swayne, was supposed to have shortened her life by repining over the loss of her fortune, which had been invested in the South Sea Stock. Elizabeth was educated by her father, who made no distinction between her and her brothers. Though slow at first, she afterwards made rapid progress in the learned languages, to which she added Italian, German, Spanish, and French: she acquired the last in the house of a Protestant refugee minister, and the three former by her own exertions. Her proficiency in these studies did not lead her to neglect needle-work, music, or the other accomplishments common to her sex. Mrs. Carter's earliest productions appeared in the 'Gentleman's Magazine,' under the signature of Eliza. In 1738 she published some poems in a very thin 4to volume, which were succeeded in the year following by a translation of some strictures, by Crousaz, on Pope's 'Essay on Man.' In the same year she translated from the Italian of Algarotti, 'An Explanation of Newton's Philosophy, for the use of Ladies, in Six Dialogues on Sight and Colours.' These publications, appearing before their author was twenty-two, gave her immediate celebrity, and brought her into correspondence with most of the learned of that day. Among others may be mentioned Bishop Butler, the author of the 'Analogy,' Dr. Benson, bishop of Gloucester, and Archbishop Secker; Dr. Johnson, Sir Joshua Reynolds, and Burke. In the midst of her literary occupations, she undertook the task of entirely educating her youngest brother for the university, and performed it so as to merit the encomium of his examiners upon his admission. During her intervals of leisure she translated Epictetus, not with a view to publication, but for the amusement of her friend Miss Talbot, to whom the sheets were sent as they were finished, and shown to Archbishop Secker, who took an interest in the progress of the work. In compliance with the wishes of her friends, she sent her translation to the press, and on its publication the literary journals at home and abroad were full of her praise. Dr. Johnson availed himself of her pen for a paper (No. 44.) for the 'Rambler.' Of her learning he thought so highly, as to say, when speaking of an eminent scholar, that 'he understood Greek better than any one whom he had ever known except Elizabeth Carter.' This learned lady was never married. She lived to the advanced age of eighty-nine, having died in 1806, leaving behind her a character adorned by finer qualities than even those of a highly cultivated understanding. (Pennington's *Memoirs*.)

CARTERET, PHILIP, a naval officer, who commanded the *Swallow*, which sailed August 22, 1786, on a voyage of discovery to the South Seas, under the orders of Captain Wallis, who sailed in the *Dolphin*. The *Swallow* being a bad sailer, the two ships were unable to keep company, and were at last parted in a gale of wind. Captain Carteret's voyage may therefore be considered as a separate expedition, and several interesting geographical discoveries were the result.

He arrived in England Feb. 20, 1789, after an absence of two years and a half. An account of his voyage is given by Dr. Haworth in the introduction to his 'Narrative of Captain Cook's First Voyage.'

CARTES, DES. [DES CARTES.]

CARTHAGE, MAGNA CARTHAGO, called by the Greeks Carthodon (*Καρθόν*), an ancient city and state, long the rival of Rome, was a colony of the Tyrians, and was built, according to tradition, about 100 years before Rome. There seems to have been an older Phœnician settlement on the spot, which, according to Appian and others, was founded before the siege of Troy, and hence much confusion has arisen concerning the age of Carthage. Most ancient writers agree in following an old story or tradition, that Carthage was founded by Elissa or Dido, whose husband being murdered by his brother-in-law Pygmalion, king of Tyre, fled with many attendants and other citizens, and landed on a peninsula on the coast of Africa, between Tunis and Utica, which were older Phœnician colonies. She purchased or agreed to pay rent for a piece of ground to build a town upon, which was called Retzura or Bosra, i. e. the castle, a name which the Greeks altered into Byrsa, 'a hill.' The name of Byrsa, and perhaps the shape of the peninsula, which resembled an ox hide, gave rise to the well-known fable of the manner in which the unsuspicious Libyans were cheated out of their ground. As the town increased, the inhabitants excavated a port, which was called Cothon, and became a great maritime and commercial emporium. This is the part of the town which Dionysius and Velleius Paterculus say was built 60 years before Rome, 813 B.C. The Magara or Magalia, which was like a great suburb with fine gardens, probably owed its name to the first Phœnician habitations, called Magar, or Magalia in the language of the country.

Of the early history of Carthage during more than three centuries we know little or nothing, except that it became a great commercial and maritime state. What we know of its institutions is derived chiefly from a chapter in Aristotle's *Politics*, in which he speaks of its government as one of the best constituted in his time, having never yet been subject to popular commotions or exposed to the attempts of tyranny. If Aristotle's work on Constitutions were not lost, we should probably have a much fuller account of the Carthaginian government and social state.

The government of Carthage was municipal; and the city ruled over all the rest of the country. The constitution was a mixed aristocracy. The chief authority was vested in the senate, which appears to have been a numerous body composed of the principal citizens. It was not an exclusive aristocracy, nor essentially hereditary, but was recruited out of the class of the more wealthy citizens, or those who had rendered great services to the state. Whether it supplied its own vacancies, or some other mode of election was resorted to, is not known. The senators appear to have been for life. The senate contained within itself a select body or council of state, which the Greek writers call Gerusia. Aristotle (*Politica*, ii., 20) says the Carthaginians had a body of 104 magistrates, similar to the Ephori of Sparta, but selected with greater discernment from among the most worthy; and that the kings and the Gerusia of Carthage resembled the kings and the Gerusia of Sparta in their respective offices. Justin says that the Gerusia was a select body chosen from among the senators to watch over and investigate the conduct of the magistrates, and especially of the generals returning home from foreign command, and that it was first established at the time when the house of Mago, by its vast influence and popularity, excited fears of some ambitious designs (about 400 B.C.). It answered therefore to the Spartan Ephori, or to the Council of Ten at Venice, though it was much more numerous, for the Carthaginian Gerusia is said to have consisted of 100 members. Two attempts at establishing tyranny were actually made,—one by Hanno, 340 B.C., and the other by Hamilcar, 306. They both failed, and their authors suffered death. This 'Council of the Hundred' is also mentioned by Aristotle as forming the highest magistracy, and deciding all causes. It was probably the same as the 'Council of 104.' The Council were also guardians of the public morals, and, like the other civil magistrates, received no salary. The members, according to Aristotle, were elected by the Pentarchies, an institution of which we know nothing more than that they managed the principal affairs of the state, that they continued in

office for a long time, filled up their own vacancies, and that no one was admitted into them who had not previously served the state in some official capacity. From their name it would appear that they were bodies composed of five individuals each. It is probable that they were permanent committees of administration chosen from among the senate.

Two Suffetes, probably Shophetim or judges, like those of the Hebrews, and whom the Greek and Roman writers call kings, appear to have been at the head of the executive; they presided in the senate, and laid before that assembly their reports on public affairs. Aristotle says that the main difference between them and the kings of Sparta was that the office of the former depended upon election, while that of the kings of Sparta was hereditary in two families. Cicero (*De Republica*) compares the suffetes to the old kings of Rome, and contrasts them with the annual consuls of the Roman Republic. It would seem therefore that the suffetes were for life, and that we might compare them to the Doges of Venice. Of their mode of election we are ignorant. The election of the generals and foreign governors, which was the next office to that of suffete, took place in the Gerusia, but was afterwards referred to the senate and the people for their approbation. A suffete was at times general also, and as such headed the armies of the Republic, while his colleague remained at home. The generals, called strategos by the Greek historians, were distinct from the boetharchs, or civil governors. When the senate and the suffetes could not agree upon some particular points, the question was referred to the people or citizens at large for their decision. Of the mode of assembling the citizens and taking their votes we are ignorant, as well as of the other occasions in which they participated in the political power. It seems however that the citizens were consulted on important occasions, concerning peace or war, &c. The magistrates were either elected by the people or proposed by the senate, and approved by the people, and Aristotle observes that bribery was resorted to, and that offices were bought and sold at Carthage. Aristotle speaks of dinners given by various societies, probably like our clubs, in which political questions were discussed. Livy speaks of their political circuli, clubs, or *cercles* as they are now called in French. It is also said that they held their meetings and councils at night time. Aristotle observes that in the choice of magistrates the qualities required were their wealth, their personal character, and merits, and their popularity, which shows that the people had a real power in the elections. Upon the whole it would appear that the constitution of Carthage resembled that of Venice previous to the great council or patrician body of the latter republic being made exclusive and necessarily hereditary, by the Doge Gradengo in 1297, by the famous decree called 'La Serrata del maggior Consiglio.' Some people have drawn a fanciful parallel between Carthage and England; but this is a very superficial view of both states: Carthage never had an extensive compact territory with many millions of an homogeneous population like Great Britain; its armies were almost entirely composed of mercenaries, and there are besides numerous other discrepancies between the two countries and their respective institutions.

Of the private and domestic manners of the Carthaginians we know very little. Being a great commercial and maritime community the people must have been busy, and have been at least comparatively free from the vices and depravity resulting from idleness. We hear of no gladiators' fights or other barbarous pastimes in Carthage as at Rome. Their punishments however were severe, and even cruel. Crucifixion was the most common mode of death. We may gather from Polybius, Appian, and others, that conjugal and parental feelings were strong among them. There was, as we have said, a censorship of public morals, and there is reason to believe that sumptuary laws also existed. The magistrates during the time of their office were required to abstain from wine. All these circumstances bear favourable evidence in favour of Carthaginian manners, at least in the earlier part of their political existence. Their religion or mode of worship, which was originally gloomy and cruel, they derived from Phœnicia. Melcarth, 'king of the city,' was their tutelary deity, and was perhaps the same as the Meles or Moloch, to whom they immolated the children of the noblest families to propitiate his wrath, until the cruel practice was abolished by the treaty with Gelon of Syracuse. Astaroth or Asarte, the

goddess of the moon, was another of their deities. They had also on the summit of Byrsa a magnificent temple sacred to Æsculapius. We hear of no sacerdotal caste possessing exclusive influence at Carthage. This subject has been investigated by the late Dr. Münter, bishop of Zealand in Denmark, in his *Religion der Karthager*; Copenhagen, 1821.

Although a people essentially commercial, the Carthaginians were remarkably attentive to agriculture, and their wealthy citizens used to employ their surplus money in the cultivation and improvement of their estates. The country in the neighbourhood of Carthage, and indeed all that tract which formed its real territory, and which corresponds to the present state of Tunis, was beautifully cultivated and extremely fertile. When Agathocles landed in Africa, and when Regulus, half a century later, Scipio Africanus, half a century later still, and Scipio Æmilianus, another half a century after that, invaded the Carthaginian territory, their march lay through rich fields covered with herds of cattle, and irrigated by numerous streams; vineyards, and olive grounds were spread on every side, innumerable small towns and villages were strewed over the country, and as they drew near to the 'Great Carthage' the neighbourhood was thickly studded with the country seats of the wealthy citizens. Mago, a suffete of Carthage, who is supposed by some to be the same as the head of the powerful family of that name, who flourished about 550 B.C., wrote a work on agriculture in 28 books, which is the only work mentioned as having been carried away by the Romans out of the libraries of Carthage when they destroyed that city, and which was translated by D. Silanus, but is unfortunately lost. Varro, Pliny, and other Roman writers have borrowed considerably from this work, which they quote with great praise. We are told by Polybius that the Carthaginians derived their public revenue from the taxes paid by the provinces.

The foreign policy of the Carthaginians was grasping, jealous, and often inhuman. This policy however dates from the time when Carthage became a conquering nation, which was in the fourth century of its existence, when the sons of Mago invaded Sardinia and Sicily. Before that event they seem to have contented themselves, like their Phœnician progenitors, with trading both inland and by sea, and establishing factories on the western coasts of the Mediterranean for carrying on an exchange trade with the natives. They early took possession of the smaller islands near their own coasts, such as Melita or Malta, Gozo, Lampedusa, and afterwards of the Balearic and the Lipari islands. The Balearics produced wine, oil, and fine wool, and Malta was celebrated for its cloth manufactures.

The intercourse of the Carthaginians with their mother country Tyre seems to have been very closely maintained. We read in Josephus (*Cont. Apion.*, lib. i.) that they sent assistance to the Tyrians when besieged by the king of Babylon, about 600 years B.C., and afterwards when Tyre was besieged, and taken by Alexander the Great, the Carthaginians afforded a refuge to some of their unfortunate fellow countrymen. Their policy and their old enmity towards the Greeks, originating perhaps in commercial rivalry, led them to enter into correspondence with the Persian kings, especially at the time when Darius and Xerxes invaded Greece. They also joined the Etruscans at an early period against the Phœcians, who had settled in Corsica, and afterwards the Ligurians against the Phœcean colony of Massilia (Marseilles), by which however they were defeated at sea, and precluded from forming establishments on the coast of Gaul.

Mago was the first who introduced military discipline, and made Carthage a conquering nation. He is said to have freed his country from the tribute or rent which they still paid to the Libyans for the original ground on which they built their city. As Mago however lived in the fourth century after the building of Carthage, it is not likely that the people of that city had till then confined themselves to the original grant of territory. We know that it was their policy to establish colonies among the Libyans, by means of which a mixed race was formed, called by Polybius Libyo-Phœnicians, as distinguished both from the pure Phœnicians of Carthage, Utica, and other maritime towns, and from the Nomades or Numidians of the interior. These Libyans, among whom the Carthaginians settled, were husbandmen, or became such by the example of their guests; they had fixed habitations, and they are evidently the same

whom Herodotus mentions as living north of the lake Tritonis, and distinguished from the Nomadic Libyans. He calls them by the names of their tribes, the Maxyes, Zæcees, Zygantes, &c., which they still retained in his time, but which afterwards became obliterated as the populations amalgamated themselves with the Carthaginian colonies, and made altogether one body of subjects of that republic. In the time of Herodotus they were apparently in the first stage after their transition from their aboriginal wild state to that of permanent agriculturists.

The real territory of Carthage seems to have extended southwards as far as the lake Tritonis, and W. not much beyond the frontiers of the present state of Tunis, for we know that Cirta, the modern Constantina, was the capital of an independent Numidian kingdom. But even in the tract of territory which may be considered as belonging to Carthage there were along the coast several old Phœnician colonies, such as Utica, Leptis, Hippo, Hadrumetum, which appear to have stood in the relation of allies to Carthage, retaining their municipal independence. But the political influence and indirect sway of Carthage extended much further inland over many tributary native chiefs, and it had settlements all along the N. African coast, eastwards as far as the Philænum Arce, on the boundary of Cyrene, in the most southern recess of the Great Syria, and westwards as far as the pillars of Hercules. Diodorus mentions various nations who inhabited North Africa,—the Phœnicians or Carthaginians along the coast, the Libyo-Phœnicians, who inhabited part of the territory subject to Carthage, and especially the district of Byzacium, the Libyans Proper, who spoke a different language from the Punic, and the Nomades or Numidians.

The first foreign conquest attempted by the Carthaginians seems to have been that of Sardinia, under one Malchus, perhaps Melech, who failed: it was renewed by Hasdrubal and Hamilcar, the sons of Mago. Hasdrubal, of whom we are told that he had been eleven times general, fell in battle in Sardinia; but his brother Hamilcar succeeded in reducing part of the island, where the Carthaginians built the colonies of Caralis and Sulei. It was about this time, 490 B.C., that Darius, according to Justin (xix. 1), sent an embassy to Carthage, requesting assistance against the Greeks, which the Carthaginians declined furnishing. About 480 B.C. Hamilcar was sent to Sicily with a great force, which has been probably exaggerated by Diodorus, who states it at 300,000 men. This was the first attempt of Carthage to conquer that fine island, and it was made at the instigation of Anaxilas the tyrant of Messana, and of his son-in-law the tyrant of Himera, who being expelled his country had taken refuge at Carthage. The Carthaginians landed at Panormus, which, as well as Soluntum and Motya, were old Phœnician settlements, and moved thence to besiege Himera. Gelon, the tyrant of Syracuse,

the assistance of the place, and by a stratagem surprised the Carthaginian camp, killed their commander Hamilcar, set fire to the ships, and totally defeated their army. The whole Carthaginian force was either destroyed or taken prisoners. Herodotus says that the battle of Himera happened on the same day as the battle of Salamis. On the news of the defeat the senate of Carthage sent messengers to Gelon to request peace, which Gelon granted, on condition that Carthage should pay 2000 talents and send to Syracuse two ships completely equipped, and also that the Carthaginians should abolish the cruel practice of sacrificing human victims to Melcarth. The Carthaginians, overjoyed with the peace they had thus obtained, made a present to Demarata, Gelon's wife, who had favoured its conclusion, of a crown of gold of the value of 100 talents. There was after this a period of 70 years of peace, during which Carthage seems to have reached the highest point of its commercial prosperity. It was during this time that it sent two fleets to explore the western coasts of Africa and Europe. The first was commanded by Hanno, a Suffete, perhaps the Hanno son of Hamilcar, who had died in Sicily. He took out with him 30,000 colonists, of the rural population, whom he distributed in six settlements on the W. coast of Africa. For particulars of this celebrated expedition see HANNO. The other expedition under Himileo (there was another son of Hamilcar of the same name) was sent round the coast of Lusitania and northwards as far as the Æstrymon Cape, which some suppose to be Cape Finisterre. But the only information that we have concerning this voyage is derived from Festus Avienus's poem,

who says (how truly is a question) that he wrote it from the Punic annals: his account is extremely confused and perplexing. It seems that the Carthaginians had discovered not only the Fortunate or Canary Islands, but Madeira also. A large island with rivers and forests is mentioned, the position of which they kept concealed as a state secret, intending it as a place of refuge in case of some great national catastrophe. Some have fancied from this that they had discovered part of America. (Heeren, *Researches into the Commerce and Policy of the Carthaginians*; Lelewel, *Die Entdeckungen der Carthager und Griechen auf dem Atlantischen Ocean*.)

The second Carthaginian expedition into Sicily took place about 410 B.C. The people of Egesta or Segeste, being oppressed by those of Selinus, applied to Carthage for assistance. Hannibal, a Sufflete of the house of Mago, sent messengers to Syracuse to request their joint mediation between Selinus and Segeste, but in reality to sound the opinion of that state, the most powerful of Sicily. But the Syracusans, who were distracted by civil factions, answered that they should remain neutral. The Carthaginians then sent first a small force to relieve Segeste, and afterwards landed a much larger force, with which they besieged Selinus. In this siege they employed moveable towers and battering rams. After a desperate defence Selinus was taken, plundered, and burnt. They next took Himera, which they treated in a like manner, 3000 prisoners being slaughtered to appease the manes of Hamilcar. The next attack was on Agrigentum, which was also taken 406 B.C. [AGRIGENTUM.] When the Carthaginians attacked Gela, Dionysius the elder, tyrant of Syracuse, interfered, and a series of wars began between him and the Carthaginians, which, with some interruption by truces, lasted till the death of Dionysius. [DIONYSIUS.] The wars were renewed under Timoleon [TIMOLEON], who at last made peace with Carthage, by which the territory of the latter state in Sicily was limited to the west extremity of the island, the river Halycus, between Selinus and Lilybœum, forming its eastern boundary. War broke out again between Carthage and Syracuse about 310 B.C., when Agathocles was tyrant of the latter city. It was on this occasion that a large fleet, intended for Sicily, soon after leaving Carthage, was dispersed by a storm, in which sixty galleys and 200 transports were lost. The loss was felt to be so great, that the walls of Carthage were hung with black, as in times of great national calamity. It is a remarkable fact that the Carthaginians, although by profession a maritime people, were singularly unlucky in storms and naval fights. They however assembled an army in Sicily, and totally defeated Agathocles, 309 B.C., who resorted to the bold attempt of carrying the war into Africa. This was the first deadly thrust at the power of Carthage, whose weak point being thus discovered, the example was afterwards followed by the Romans. [AGATHOCLES.]

After the death of Agathocles, Pyrrhus, who had married his daughter, came over to Sicily to oppose the Carthaginians. He overran their territory, and took all their towns, except Lilybœum. Pyrrhus however returned to Italy, and the Syracusans elected Hiero for their commander. Hiero began by attacking the Mamertines, a body of Campanian mercenaries who had served under Agathocles, but being dismissed after his death, had gone to Messina, where, after being kindly received, they suddenly fell upon the citizens, killed or drove them all away, and took possession of their houses, wives, and property. Being hard pressed by Hiero, they applied to the Carthaginian naval commander, who was stationed at Lipara. The Carthaginians came and took possession of the citadel. The Mamertines afterwards revolted against them, and applied to Rome for assistance against both Hiero and the Carthaginians. This gave rise to the first contest between Carthage and Rome, 265 B.C. [PUNIC WARS.]

The result of the first Punic war, which ended 242 B.C., was that Carthage lost Sicily and the Lipari islands. This war was followed by another, nearly as destructive to Carthage. The mercenary troops who had served in Sicily, and had been disbanded in Africa after the peace, without being paid their full stipend, rose under two chiefs, devastated the territory of Carthage, threatened the city, and carried on the war for several years, until Hamilcar Barca, who had already distinguished himself in Sicily in the latter period of the war against the Romans, succeeded in subduing or rather destroying the mutineers. Polybius calls this the Libyan war, and he gives a detailed account of it. It was attended

with circumstances of the greatest atrocity on both sides. Indeed the Carthaginians, who employed chiefly mercenary troops, though always commanded by Carthaginian officers, could not rely upon the attachment of these soldiers, and they seem also to have been wantonly prodigal of their blood, and often unjust to them, when they stood no longer in need of their services.

After the end of the war of the mercenaries, of which the Romans took an unfair advantage by seizing upon Sardinia, and driving away the Carthaginian garrison, Hamilcar Barca was sent over to Spain. That skilful commander turned all his thoughts to establishing the power of Carthage over that rich country, and thus gaining a compensation for the loss of Sicily and Sardinia. It was before setting off for Spain that he made his son Hannibal, then a boy nine years old, swear on the altar eternal hatred against Rome.

It does not appear that the Carthaginians held any extent of territory in Spain before Hamilcar's time, though they had factories on the south coast. The inhabitants of Gades, an old Phœnician colony, connected with Carthage by common descent and commerce, had asked assistance against some native tribes, and this had probably furnished a pretence for the first Carthaginian settlements on that coast. During nine years that Barca remained in command in Spain, he extended the dominion of Carthage over the south and east part of that country, and founded the town of Barcino or Barcelona. These conquests of course were not effected without much oppression of the natives, and we are told that Hamilcar remitted large sums to Carthage in order to strengthen the influence of his party in the senate and among the people, which were then divided between two rival factions, that of Barca and that of Hanno, each taking the name of the leading family. Hamilcar was killed in a battle against the natives (Appianus, *De Reb. Hispan. v.*), and was succeeded by Hasdrubal, his son-in-law, who took young Hannibal as his colleague. The Saguntini, who are said to have been a colony from Zacynthus, being pressed on all sides by the Carthaginian conquests, sent deputies to Rome for protection. The Roman senate sent deputies to Carthage, and a treaty was concluded, by which the river Iberus (Ebro) was to be the limit of the Carthaginian possessions in Spain, and moreover the Saguntini and other Greek colonies south-west of the Iberus were to remain free and independent. Hasdrubal some time after was killed by a native while hunting, and Hannibal, then twenty-six years of age, was proclaimed his successor by the army, a choice which was confirmed by the senate of Carthage.

He began his command by the siege of Saguntum, which led to the second Punic war, 218 B.C. [HANNIBAL.] By the peace (201 B.C.) which terminated that memorable contest, the power of Carthage as an independent state was entirely annihilated. Besides the large sums they had to pay, the Carthaginians gave up Spain, and all their other settlements beyond Africa; they delivered to the Romans all their ships of war except ten triremes, and all their elephants, and they bound themselves not to carry on war either out of Africa without the permission of Rome. Massanissa the Numidian king remained as a watchful and interested trustee for the execution of the latter condition. The sequel of the history of Carthage presents but a melancholy picture of the humiliation and decline of a once powerful state. The Carthaginians kept the treaty faithfully; they bore patiently during half a century with the impetuosity of Rome, and the annoyances of its ally, Massanissa, until the latter seized upon an extent of territory called Tysen, with fifty villages upon it, within the Carthaginian boundary Fossæ Punice, as fixed by the first Scipio. They then complained to Rome, which sent a commission, of which Cato the elder was one. That ruthless inflexible old man inspected every part of the great commercial city, and being astonished at the sight of its still remaining wealth and magnificence, persuaded himself that nothing but its ruin could insure the dominion of Rome. Hence his well known burthen to the senate on his return, 'Delenda est Carthago.' Some of the Roman senators however, and Scipio Nasica among the rest, men of more enlarged views, were for moderate and conciliatory measures. Scipio Nasica himself was next appointed commissioner to arbitrate between Carthage and Massanissa. He went to Carthage, and had nearly settled all controverted points, when Gisco, a Carthaginian demagogue, roused the populace to assault Scipio, who was obliged to save himself by flight.

Carthage, like all commercial cities in their decline, was distracted by factions; one party was favourable to Momo, another to Massanissa, and another, with Gisco and Hasdrubal at their head, called themselves the popular or National party. The friends of Massanissa were exiled by the popular party, and Gulussa, the son of Massanissa, who had come to Carthage to negotiate, was not allowed to enter the gates, and on his way back his escort was attacked by a party of Carthaginians, and some of his men were killed. Massanissa, who was then nearly 90 years of age, invaded the territory of Carthage. The Carthaginians opposed force to force, and Hasdrubal was appointed commander. While the two armies were fighting, Scipio Aemilianus, son of Paulus Aemilius, and grandson of Scipio Africanus by adoption, arrived in Massanissa's camp on a mission from Spain, where he was then serving. The result of the fight was unfavourable to the Carthaginians, who retreated to their camp, in which they were blockaded by Massanissa. Being reduced by famine, they were obliged to surrender, give up their arms, and pass under the yoke; after which, as they were marching on, exhausted and broken-spirited, towards Carthage, Gulussa fell upon them with his Numidian cavalry, and made a frightful slaughter. Hasdrubal, the commander, escaped, but being condemned to death as a traitor or coward, he collected the runaways and many outlaws, and formed a body of 20,000 marauders, who lived at discretion in the interior of the country. The city of Utica, an old Phœnician colony, to save itself from the impending storm, sent deputies to offer itself to the Romans. Rome declared war against Carthage, 149 B.C., under the pretence of its having violated the treaty by defending itself against Massanissa. The consuls Marcus Censorinus and Manlius Nepos were appointed to the command of the fleet and of the land force; and they received secret orders from the senate not to desist from hostilities until Carthage was destroyed. The Carthaginians, overcome by so many calamities, having lost their army, and being without ships, allies, or mercenaries, sent deputies to Rome with full power to make peace at any cost. The deputies were referred by the senate to the consuls, who had then arrived in Sicily, and who would prescribe to them the conditions, by fulfilling which Carthage should preserve its laws, its liberty, and its territory. Having repaired to the consul's station at Lilybœum, they were required to deliver as hostages 300 young men of the first families of Carthage. This being complied with, the consuls sailed for Utica, where, having landed their troops, they encamped at the old Castra Scipionis. They then gave a public audience with great pomp and state to the Carthaginian deputies, who appeared as suppliants before them, and were required to give up all their arms, as they had no more occasion for them, the Roman people taking them under their protection. The arms were delivered to the number of 2000 catapultæ, 200,000 complete armours, besides an immense number of pears, swords, bows and arrows, &c. This being done, the deputies waited to hear the final sentence. The consuls then signified to them that Carthage must be razed to the ground, but that the inhabitants might rebuild their houses any where, provided it were 10 miles distant from the sea, and there were no walls or fortifications. The scene that followed, first in the Roman camp, and afterwards within Carthage, on the return of the deputies, is well described by Appian. The indignation of the citizens at the base treachery of the Romans overcame all considerations of prudence or personal safety. They determined on defence, and the third Punic War began. It lasted only three years, and ended with the utter destruction of Carthage, 146 B.C. The horrors of that siege, the desperate resistance of the Carthaginians, the self-devotedness of their women, are described by Appian. Of 700,000 people who lived within Carthage, only 50,000 surrendered to Scipio and were saved. By a decree of the Roman senate, every part of the city was razed to the ground. The destruction of a great commercial city, the first in the world at the time, previously resolved upon in cold blood, after fifty years of peace, and without any fresh provocation, and against a defenceless people, who had thrown themselves entirely upon Roman generosity, was one of the most brutal acts of Roman policy. To Africa the destruction of Carthage was a retrograde step in civilization, for there was never afterwards a native power in that part of the world that could be compared to Carthage. The Carthaginian colonies beyond the pillars of Hercules were forgotten, and the key to their and extensive trade was lost. The literature of

Carthage likewise perished; the Romans gave its libraries to their Numidian allies, and we know, through Sallust (*De Bello Jugurth.*) that king Hiempsal had a collection of Carthaginian historians, from which Sallust derived some information on the early history of Africa. Pliny mentions a collection of African chronicles compiled by Joba, and extracted from Punic, Libyan, Greek, and Latin authorities; this work, however, is lost.

About 30 years after the destruction of Carthage, the Græci attempted to establish a colony on its ruins; but the settlement made little progress until Julius Cæsar, and Augustus, after him, sent colonies to build a new town, which was called Colonia Carthago. It stood on the S.E. part of the peninsula, between Cape Carthage and Cape Cammar, and occupied but a comparatively small part of the ground of the old city. Pliny called it 'Colonia Carthago, magnæ in vestigiis Carthaginiæ.' It rose, however, to considerable splendour, had its cotton or harbour, and became the first city of Roman Africa. In Christian history it is known for its councils and for the spiritual labours of St. Augustine. In 439 A.D., it was taken by the Vandals under Genseric; it was retaken by Belisarius in 533; and lastly was taken and destroyed by the Saracens in 698. Thus ended the second Carthage, after an existence of about seven centuries. The ruins which are now seen on that coast belong to the Roman Carthage; there are no remains of the Tyrian city, except the large cisterns and perhaps the ruins of the great aqueduct. It seems probable that the old or great Carthage occupied the N. part of the peninsula, between Cape Cammar and Cape Carthage, where substructure are still seen under water; and it perhaps extended also to the S.W. of Cape Cammar, where the whole appearance of the land is changed since the time of old Carthage. The gulf between Cape Cammar and the point of Porto Farina went much deeper inland than it does.

The alluvia of the Bagradas, and the sands raised up by the N.W. winds which prevail on this coast, have filled up this space for several miles. The shape of the peninsula of Carthage is completely altered; the isthmus, three miles broad, which was formed by the lake of Tunis on one side and the gulf above mentioned on the other, is now obliterated on the latter side by the main land, which has formed itself along side of it, extending N.W. to the spot where Scipio once stood. The lower course of the Bagradas is also altered. The river at one time entered the sea nearer Carthage than it does now; it stood between Carthage and the Castra of Scipio, whereas it now enters the sea on the other or N. side of the Castra. The remains of Utica are now several miles from the sea-shore. (See the topographic map of Carthage in Shaw's *Travels*.) It is possible that the cotton or harbour of the Tyrian Carthage opened into the gulf, which is now filled up, to the leeward or S.W. of Cape Cammar. As for Byrsa, there are several hillocks which may answer to it, as it was not the only hill within Carthage. Megara, which was a suburb with spacious gardens, extended probably over a great part of the

island. The most recent and accurate investigation on the site of the Tyrian Carthage is contained in Estrup's *Lineæ Topographiæ Carthaginiæ Tyriæ*, with a map, 1824. Estrup was a Danish scholar, who made use of the MSS. of Camillo Borgia, a Neapolitan traveller, who had examined the ground attentively, and who died at Naples without being able to publish his work. See also E. Stanley's *Observations on Tunis and Cape Carthage*, 1786. For the commerce and colonies of Carthage, the reader may refer to Heeren's *Researches*, and the authorities there quoted; and for its political history, to Bötticher's *Geschichte der Karthager*, 1827.

[Mus. Mus. Antiqu. Mus. Copper.]

CARTHAGINUS TINCTORIVS, a pretty animal found with the Egyptians and the Libyans. It has an erect

dricul stem, branching near the summit, a foot or two high, and furnished with sharp-pointed oval, sessile, somewhat spray leaves. The flowers grow in heads, enclosed in a roundish spiny involucre; the florets are of an orange-yellow, becoming red when dried. These latter contain a colouring principle called Carthamite, which is employed by dyers as the source of some of the more delicate rose-colours, and the rich scarlet called ponceau; it also constitutes the basis of the cosmetic known by the name of rouge.

The dried flowers of carthamus are exported in great quantities from Egypt, and are very like saffron to the eye, on which account they have been employed to adulterate that drug; and the plant itself has acquired the name of bastard saffron, or safflower. McCulloch states that 2772 cwt. of this article was imported in 1831.

CARTHUSIANS. The Carthusian monks were a branch of the Benedictines, whose rule, with the addition of a great many austerities, they followed. Bruno, who was born at Cologne in Germany, first instituted the Order at Chartreux, in the diocese of Grenoble in France, about A.D. 1080; whence the monasteries of the Order, instead of Chartreux-houses, were in England corruptly called *Charter-houses*. The rule of the Carthusians, which is said to have been confirmed by Pope Alexander III. as early as 1174, was the most strict of any of the religious orders; the monks never eating flesh, and being obliged to fast on bread, water, and salt one day in every week; nor were they permitted to go out of the bounds of their monasteries, except their priors and procurators, or proctors, and they only upon the necessary affairs of the respective house.

The Carthusians were brought into England in 1180 or 1181, by King Henry II., almost as early as their establishment at Grenoble, and had their first house at Witham in Somersetshire. Their habit was all white, except an outward plaited cloak, which was black. Stevens, in his *Continuation of Dugdale's Monasticon*, says there were but five nunneries of this austere order in the world, and but 167 houses of these monks. In England there was no nunnery, and but nine houses of this order. These nine houses were at Witham and Henton in Somersetshire, the Charter-house at London, Beauvale in Nottinghamshire, St. Anne's near Coventry, Kingston-upon-Hull, and Mountgrace in Yorkshire, Eppworth in the Isle of Axholm, and Sheue in Surrey. Licences for two or three other houses were obtained at different times, but they do not appear to have been established.

Dugdale has given the statutes of the order from a MS. in the Cottonian library, marked Nero A. iii. Some constitutions made at a general chapter of the order held in 1411, are also preserved in the Cottonian MS., Calig. A. ii. fol. 139. The Cottonian MS., Nero A. m., besides the statutes of the Order already mentioned, contains the oaths of those who entered the Carthusian order, with the graces which were used both before and after dinner and supper.

(*Histoire des Ordres Monastiques*, vol. vii. p. 366; Tanner, *Notit. Monast.*, edit. Nasm., p. 9; Dugdale's *Monasticon*, new edit. vol. vi. pt. i. p. 3.)

CARTILAGE, commonly called gristle, a substance intermediate in density between the membranous and bony structures of the body. It is distinguished from every other texture by its pearly whiteness, its smoothness, its firmness, and its great elasticity. When divided it appears to be perfectly homogeneous, without fibres and without lamium; but when examined after prolonged maceration, it is manifest that it possesses a fibrous structure. The component fibres are inferior in firmness only to those of bone; they are so brittle, that if forcibly bent they give way and break, and yet they are endowed with a high degree of elasticity. They are united by cellular tissue so exceedingly condensed, that it can be distinguished from the cartilage itself only after protracted maceration or long-continued boiling. The nutrient arteries of cartilage are so minute that they are incapable of admitting the red particles of the blood; but that they admit the finer particles of the nutritive fluid is manifest from the new matter which is deposited during growth, and from the yellow colour which the cartilage assumes in jaundice. No lymphatic can be detected in cartilage; but the presence of lymphatic vessels in it is demonstrated by the absorption that takes place in cartilage in the progress of ossification, and in the progress of many diseases. No nerve is visible in this substance to the eye, but the pain induced in it by disease proves that it is not destitute of nerves. Homogeneous as this substance appears, it is truly

organised, containing every constituent which enters into the composition of organic structures.

Chemically considered, cartilage appears to consist of condensed albumen combined with a small portion of earthy phosphate; its chemical composition thus showing its close relation to bone. According to Dr. Davy, 100 parts of cartilage consist of albumen 44.5, water 55.0, phosphate of lime .5.

Cartilage is not only closely allied to bone in the mechanical arrangement of its component fibres and in its chemical composition, but it sometimes supplies the place of bone, as in the fetus and in young persons. Cartilages of this class, which regularly disappear as ossification advances, are called temporary, in contradistinction to the permanent, which remain during all periods of life. Permanent cartilages either cover the extremities of the bones in the moveable joints or articulations, and are thence called articular; or are attached to the extremities of the ribs, and are thence termed costal. The articular cartilage consists of a layer of the same shape as the extremity of the bone which it covers, varying in thickness from one or two lines to the fraction of a line, and over its external or free surface there is always reflected a fine and delicate membrane termed the synovial, which secretes the fluid by which the joint is lubricated and its free and easy motion secured, denominated synovia or joint oil.

The costal cartilages, which are cartilaginous productions of the osseous ribs, are much larger and thicker than the articular, assist in the formation of the thoracic cavity, and perform a very important part in the function of respiration.

The distinctive property of this peculiar form of organised matter, to which the name of cartilage has been given, is elasticity, on which depends the specific use of this substance in the economy. It is mainly an adjunct to bones, counteracting certain evils which, but for the intervention of some substance of this kind, must necessarily have resulted from the hard unyielding nature of the osseous fibres. Covering the extremities of bones, or interposed between layers of bony fibres, without in the least diminishing the firmness and strength of the osseous fibres, it enables the bones to yield in the shocks to which the body is exposed in the ever-varying movements of the frame, defends them from fracture and displacement, and at the same time protects the great centres of the nervous system, the spinal chord and brain, from the concussions and jars to which these tender and delicate organs would, but for its interposition, have been constantly exposed. (Bostock's *Elements of Physiology*; Grainger's *Elements of General Anatomy*; and Southwood Smith's *Philosophy of Health*.)

CARTMEL. [LANCASHIRE.]

CARTOON, from 'carta,' paper, 'cartone,' large paper, Ital.; a word used by artists to signify the full-sized drawings or studies made in chalks, or body-colour (*tempera*, as it is called in Italy), preparatory to executing any great work either in oil-colour or fresco. Cartoons are also made when the design is to be copied in tapestry.

The preparation for making cartoons is very simple: several sheets of paper are pasted together at the edges, and then strained on a frame of the size required. Sometimes the surface is primed; that is, washed with a general colour or ground, but more frequently the paper is left in its natural state, and the drawing is made either in chalks or, as above stated, in distemper. When only two colours are used, as black and white, or brown and white, it is called 'in chiaro scuro,' i. e. light and shade. The cartoon being finished, it is transferred either by laying it upon the canvass on which the picture is to be painted, and tracing the lines through with a hard point (powdered charcoal, or black lead, or chalk being first rubbed on the back of it, or on paper placed between it and the canvass), or lines are drawn over it perpendicularly and horizontally at equal distances; and exactly corresponding lines or squares being made on the canvass, the parts of the cartoon are carefully copied into them, and the colouring is then commenced. The injury which the drawing of lines over it might do to the cartoon may be avoided by straining threads across it from pins at the required distances round the frame. In fresco painting the plaster on which the work is to be executed must be wet, and only a small portion can therefore be completed at a time; the transfer of the cartoon is effected here in small compartments, either by tracing as much as the artist means to finish, or by pricking the lines through.

The great masters seldom commenced any extensive pic-

ture without first making studies or cartoons in *chiaro scuro*. Many of those by Raffaele, And. Mantegna, Domenichino, the Caracci, and others, remain to attest the laborious diligence and care with which their great works were accomplished. By this means the composition, drawing, expression, and light and shade, were all perfected before the colouring of the picture was attempted, and as these may be said to constitute the highest qualities of art, the schools that chiefly attended to them, viz. the Roman, Florentine, and Bolognese, are eminently distinguished for their *grand style*.

The finest specimens of cartoons that are known are those executed by Raffaele d'Urbino, which were sent to Flanders, in the reign of Pope Leo X., to be copied in tapestry, in two sets. One was intended for the decoration of the pontifical apartments in the Vatican: the other as a present from the pope to Henry VIII. of England. The tapestries (only shadows of Raffaele's exquisite designs) were finished, and one set is now in Rome. The other was in England till the death of Charles I., when it was purchased and carried to Spain by the Spanish ambassador.*

The cartoons, originally twenty-five in number, were left neglected at Brussels, and most of them seem to have been lost or destroyed. A few however escaped this fate, and seven are now in England in his Majesty's collection at Hampton Court. Their history, even since their arrival in England, is eventful. They were bought in Flanders by Rubens for King Charles I. At the dispersion and sale of the royal collection the cartoons were secured to the country by purchase, by Cromwell's particular command: at which time, we are told, the triumphs of Julius Cæsar by Andrea Mantegna (still preserved at Hampton Court) were valued at 2000*l.*, while the cartoons of Raffaele were estimated at only 300*l.* In the reign of Charles II. they were again consigned to neglect. They had been sent to Mortlake to be copied in tapestry, where they were seriously injured. William III. had them repaired, and built a gallery at Hampton Court for their reception. George III. removed them to Buckingham Palace, and subsequently to Windsor Castle. They were again removed to Hampton Court, where they now are.

The cartoons represent the following striking subjects from the New Testament:—

Paul preaching at Athens.
The Death of Ananias
Elymas the Sorcerer struck with blindness.
Christ delivering the keys to St. Peter.
The Sacrifice at Lystra.
The Apostles healing the Sick in the Temple.
The Miraculous Draught of Fishes.

Precluded by our limits from entering at length into the merits of the cartoons of Raffaele, we would still earnestly direct the attention of our readers to these noble creations of genius. They will be found to possess all the qualities that dignify art. In the first place, they display the greatest judgment in the artist in the selection of his subjects, and equal skill in the manner of treating them. The compositions are in the highest degree masterly, and the stories intended to be illustrated are told with the greatest perspicuity. In the details they exhibit every variety of character and expression; the mild sublimity of our Saviour, the quiet dignity of the Apostles, admiration, doubt, surprise, pain, fear, down to the careless innocence of childhood, are all portrayed with a master's hand. The women are the most perfect delineations of grand female beauty, and the children, wherever they are introduced, are models of infantine grace and simplicity. In the arrangement of drapery Raffaele was unrivalled, and the cartoons offer the finest examples of excellence in this respect. These exquisite works cannot be too often nor too carefully studied by those who desire to form a pure and elevated taste in design. The cartoons above specified have been engraved by Dornigny, Audran, and Holloway; there are also engravings of a greater number than those in the English collection, some of which are taken from the tapestries; of others it is believed the originals no longer exist. Five from tapestries represent the Adoration of the Kings—Christ appearing to Mary Magdalen—The Disciples at Emmaus—The Murder of the Innocents—The Ascension. Others are described by

Fea, in his 'Descrizione di Roma,' and Somereau, a French artist, engraved them, with the whole series, in 4to.

Two large cartoons by Raffaele are in the possession of the duke of Buccleugh; and two, said to belong to the set sent to Flanders, are in the king of Sardina's collection. There was a tapestry from a cartoon by Raffaele, representing The Descent of Christ to the Fathers, in Limbo, which the Abbate Fea tells us was destroyed by fire. It was engraved by Nic. Beatrietto, and described by Braun. For some further interesting particulars on this subject, the reader is referred to 'Istoria della Vita, &c. di Raffaello Sangio del Sr. Quatremer de Quincy,' with ample notes by its translator (into Italian), Francesco Longhena; 1 vol., Milano, 1829. Lord Francis Egerton has, at Bridgewater House, two very fine cartoons in black chalk, by Annibale Caracci. They are studies for parts of the decoration of the Farnese Palace in Rome, and offer examples of the free and grand style of design which characterised this artist's pencil.

CARTWRIGHT, EDMUND, was born April 24, 1743, at Marnham, in the county of Nottingham. His family was ancient and highly respectable, and had suffered in its fortune on account of its attachment to the cause of Charles I. Edmund Cartwright received the early part of his education at Wakefield, and being intended for the church, he afterwards went to University College, Oxford, and was elected a Fellow of Magdalen College. He afterwards held the living of Brampton, near Chesterfield, and subsequently he removed to the living of Goadby-Marwood in Leicestershire. He wrote some poetical pieces at an early age, some of which were printed anonymously. In 1770 he published in his own name a legendary poem, entitled 'Arminia and Elvira,' which was received with much favour, and soon passed through several editions. He wrote also the 'Prince of Peace' and 'Sonnets to Eminent Men.' He was for a considerable time a contributor to the 'Monthly Review.' The duties of his calling were besides varied by a literary correspondence with several eminent individuals.

In the summer of 1784, during a visit at Matlock, happening to meet with several gentlemen from Manchester, the conversation turned upon the subject of mechanical weaving. Dr. Cartwright's attention had never been directed to mechanical inventions, but though in his fortieth year, the impulse which his mind received from this accidental direction of its powers, enabled him, by the following April, to bring his first power-loom into action, which, though an extremely rude machine, soon received many valuable improvements. Its first introduction was opposed both by manufacturers and their workmen, owing to various prejudices; and a mill containing 500 of his looms, the first which had been erected, was wilfully burnt down. In 1813 there were not more than 2300 power-loom in the United Kingdom. In fact, when first introduced, and before various improvements were made in it, the machine was scarcely equal to its results to manual labour. By a parliamentary return (No. 24) made during the present session (1836), the number of power-loom in the United Kingdom is as follows:—England, 95,975; Wales, 1939; Scotland, 17,721; Ireland, 1516; total, 117,151. In April, 1790, Dr. Cartwright took out a patent for combing wool: altogether he obtained ten different patents for inventions and improvements of various kinds. In 1807, a number of the principal cotton-spinners memorialised the government on behalf of Dr. Cartwright, who had hitherto reaped little advantage from the exercise of his inventive talents. He also petitioned the legislature himself in support of his claims; and in 1809 parliament granted him 10,000*l.* for 'the good he had rendered the public by his invention of weaving.' This was a smaller sum than he had expended on his projects, but it enabled him to pass the remainder of his days in ease and comfort. He died October 30, 1823, in the 81st year of his age.

CARTWRIGHT, JOHN, brother of the preceding, was born in 1749, at Marnham, and entered the navy at an early age. Soon after his thirtieth year, he published 'Letters on American Independence;' and though attached to his profession, he declined taking part in the struggle which ensued between the mother country and the North American colonies. In 1775, he received a major's commission in the Nottinghamshire militia, an appointment which the ministry regarded with displeasure. The attainment of annual parliaments and universal suffrage became the ob-

* These tapestries were recovered and brought to England, and exhibited lately in London, but as no purchaser was found, they were bought by a foreigner, who took them to the continent.

ject of his exertions; and to further this end he was active in establishing the Society for Constitutional Information, and in co-operating with Tooke, Hardy, Thelwall, and other advocates of reform. He was a witness on the trial of the above individuals; and in 1819, was himself the object of an *ex officio* prosecution, for having with others taken steps for procuring a 'legislatorial attorney' to be returned to parliament for the then unrepresented town of Birmingham. His name is intimately connected with the early history of the question of parliamentary reform. Lord Byron, when presenting a petition from him in 1813, said:—'He is a man whose long life has been spent in one unceasing struggle for the liberty of the subject.' He possessed considerable intelligence and ingenuity, and was the author of several useful projects, and a number of pamphlets and occasional addresses. Fox once passed a high eulogium on his public and private character. Though retaining his commission in the navy, he was invariably called Major Cartwright. He died 23rd September, 1824, and would have completed his eighty-fourth year on the 28th. A bronze statue has been erected to his memory in Burton Crescent, London, by contributions from his admirers and friends.

(*Life and Correspondence of Major Cartwright*, edited by his niece, F. D. Cartwright, 2 vols., 8vo., London, 1826.)

CARUNCULA, a name applied by botanists to protuberances found occasionally surrounding the hilum of a seed. It is sometimes also called a strophilon. Parts of this kind occur on the seeds of *Euphorbia Lathyrus*.

CARUS, MARCUS AURELIUS, prefect of the prætorium under the Emperor Probus, succeeded him by the nomination of the soldiers, after they had murdered Probus, A.D. 282, in his camp near Sirmium in the Illyricum. Carus was a native of Narbo, an old Roman colony, and as such he prided himself in being a Roman citizen by birth. (See his letter to the senate announcing his nomination, in Vopiscus, *Historia Augusta*.) He made war against the Sarmatians, and defeated them. He marched next against the Persians, A.D. 283, and took with him his younger son Numerianus, leaving his elder son Carinus to rule over Italy, and the other provinces of the west, in his absence. Carus overran Mesopotamia, and conquered Seleucia and Ctesiphon, after which, as he was encamped beyond the Tigris, a great thunder-storm arose, and it was reported that the Emperor was killed in his tent by the lightning: the servants upon this set fire to his tent, and his body was consumed. His secretary, Calpurnius, however, in a letter which he wrote to the Prefect of Rome, said that the Emperor, who was already ill, died during the storm. But the strongest suspicions rested upon Arrius Aper, Prefect of the Prætorium, the same who soon after killed Numerianus. Carus reigned about seventeen months. He was succeeded by his two sons Carinus and Numerianus.

Coin of Carus.

[Brit. Museum. Actual Size. Gold, 75 grains.]

CARVING, the art of forming any hard materials into a proposed shape or figure by means of sharp instruments. It is usually understood to refer exclusively to works in ivory or wood, to distinguish it from carving in marble or stone, which comes under the term *sculpture*; or in metals, when it is called *chasing*.

The ancients used ivory to a great extent in works of art, and its union with gold, called by the Greeks *chryselephantine* sculpture, was adopted by the greatest artists. The colossal statue of the Olympian Jupiter at Elis, by Phidias, was one of the most celebrated examples of this combination. In later times carving in ivory has been confined to smaller objects, as figures, reliefs, enrichments of flowers, fruit, and other devices on vases and cups, and such objects of general use. The instruments used for carving in ivory are very similar to those employed in working in marble, consisting of chisels of different sizes, saws, rasps, and files; the polishing is effected, as in marble, by friction.

Wood of almost every description was a favourite material for carving among the ancients: and, after clay,

was doubtless, from the facility of cutting it, the first substance used for imitative art. Some figures of very remote antiquity found in the tombs in Egypt are of sycamore. In Greece many of the statues of the gods were of wood; and all those attributed to the first Dædalus were of that material, from which circumstance indeed wooden figures were called *Δαίδαλα*, or Dædalian. Wood seems to have been used for sculpture long after more valuable and durable materials were employed. Pliny and Pausanias describe many of these works, and mention the varieties of wood of which they were made. Among them were the oak, ebony, fir, cedar, box, citron, cypress, beech, fig, myrtle, olive, palm, poplar, vine, &c., &c.

For a long period in modern times there was a great demand for fine wood-carvings. The elaborately worked Gothic screens, choir-seats, and desks, in most of our cathedrals and colleges, canopies, frames for doors and pictures, cabinets, and indeed every description of furniture, are evidence of the extent to which it was employed, and of the skill of the artists. It must be admitted that many of these performances display more ability in the workmanship than good taste in the design, being, where figures are introduced, chiefly of grotesque and not unfrequently indelicate subjects. There are, however, specimens of chaste design, as well as careful execution.

One of the most eminent modern carvers in wood was Grindling Gibbon, a native of England. He was much employed by Charles II., particularly at Windsor Castle and Hampton Court. In London the choir of St. Paul's may be instanced as a work of this artist. Many of his best performances are at the country residences of some of the English nobility: the specimens at Chatsworth, the seat of the Duke of Devonshire, are admirable imitations of nature. They consist generally of dead game, sporting tackle, fruit, flowers, &c., &c. Gibbon died in 1721.

The German and Flemish carvers in ivory and wood were also very distinguished.

The woods preferred by modern carvers are the pear, lime, American pine, maple, oak, and box: and the tools they employ are round hollow chisels called gouges; others with an angular extremity called from the shape V tools; flat chisels of various sizes, and files. A mallet is sometimes used, but pressure, or a sharp blow from the bottom or heel of the hand is generally preferred. The surface is cleaned and polished with sand-papers of different qualities, by pumice-stone, and by friction.

In preparing wooden blocks for printing from, the object is engraved with instruments similar to those commonly used for engraving. This branch of the art does not therefore properly come under the term 'carving.'

CARY. [FALGARD, LORD.]

CARYA, the botanical name of the genus of North American trees which comprehends the various kinds of hickory. It was formerly combined with *Juglans*, or the true walnut; but it is distinguished by the shell of its nuts not being deeply furrowed, and by the catkins of the male flowers growing in threes. This must not be confounded with *careya*, a genus of Indian myrtaceæ.

Several species of hickory are recognized by botanists; but, according to Michaux, the timber of them all is so similar in quality that it is impossible to distinguish it. The bark of the hickory is in all cases remarkable for the lozenge-shaped arrangement of its woody tissue; the wood is coarse-grained, very heavy, exceedingly tough and strong, and red at the heart: but on the other hand it decays quickly when exposed to the weather, and it is subject to be attacked by worms. It is on these accounts chiefly employed for the shafts and springs of carriages, for large saws, such as those of bookbinders' presses, for bows, chair-backs, whip handles, wooden-cogged wheels, hoops for casks, and a variety of similar purposes. When burnt, hickory wood consumes slowly, gives out a great heat, and forms a heavy coal, which remains glowing for a long while: it is considered to be upon the whole the best of all woods for fuel: it has however the fault of crackling and scattering about its sparks.

The following are the principal kinds of hickory:—

1. *Carya oliviformis*, the Pecan or Pecana nut. (*Juglans angustifolia*, Hort. Kew.) This is a swamp species, with a slender stem, sometimes as much as 70 feet high. Its leaves are a foot to 18 inches long; their stalks are downy; the leaflets, which are 2 or 3 inches long, or as much as 5 inches on very strong shoots, are taper-pointed and firmly serrated.

Their nuts are oblong, very smooth, angular in only a slight degree, about an inch and a half long, and thinner shelled than the other sorts. The kernel is good to eat, and by far the best of the hickories; on this account the nuts are a small article of North American trade. The pecan nut is found in Upper Louisiana and New Orleans. It is common on the banks of rivers in Missouri, Illinois, and Arkansas. It does not occur, except in straggling specimens, more than 200 miles above the mouth of the Ohio.

2. *Carya sulcata*, thick-shell-bark hickory, Springfield or Gloucester nut (*Juglans laciniata*, Michaux), very common in all the low grounds adjoining the Ohio and its tributaries, where, along with three-thorned gleditschias, black walnuts, Virginian bird-cherries, American elms, planes, and different species of Acer, it forms dense forests; it is seldom found west of the Alleghanies. Its trunk is as much as 80 feet high, on which it has a noble spreading head. Its bark, like that of some of the other hickories, strips off in ribands from one to three feet long, which separate at their extremities and curl backwards, finally adhering to the trunk only by their middle. The leaves vary in length from 8 to 20 inches: in form they are very like those of *C. alba*, but they usually have 6 or 8 leaflets instead of 4, which is the invariable number in that species. The nuts are oblong, sharp-pointed at each end, with four elevated angles, and a thick shell of a yellowish brown colour, not white as in *C. alba*. They are brought to market in North America under some of the names mentioned above.

3. *Carya alba*, white-shell-bark, shag-bark, scaly-bark hickory (*Juglans squamosa*, Michaux). The shaggy appearance of the bark, adverted to in speaking of the last species, has caused the above names to be applied to this common species. It extends from South Carolina to the neighbourhood of Portland in the state of New Hampshire, where it is said to disappear. It is the most slender-stemmed of all the hickories, its trunk being sometimes 80 or 90 feet high and not more than two feet in diameter, and is described as a magnificent tree in its native forests. The young buds are woolly and slightly orange-coloured. The leaves are often 20 inches long; they have only four leaflets and an odd one, which are smooth and bright green above, finely downy on the under side, and serrated at the edge. The nuts are whitish, nearly round, hardly pointed at each end, angular, compressed, thick-shelled, remarkably small in proportion to the size of the fruit with its fleshy rind upon it. The kernel is next in quality to that of the Pecan nut. They form a common article of market commerce.

4. *Carya tomentosa*, mocker-nut hickory; so called in consequence of the smallness of the kernel compared with the size of the nut. Its leaflets are from 7 to 9 in number, slightly round, very downy on the under side; they become bright yellow in the autumn. The leaf-buds are thick, short, whitish-grey, and very hard in the winter season. The nuts are sessile, roundish, and enclosed in a rind which only opens hol- way to let them drop out; they are light brown, angular, and very little pointed. The bark of this species does not scale off, but rends into deep fissures. It grows the slowest of all the hickories; and is found chiefly in forests from New England to Virginia, and in the Alleghany. Pursh says, in fertile soils; but Michaux adds, that it nevertheless is the only hickory which makes its appearance in those sterile tracts called pine-barrens, where however it is only a scrubby bush. In the most favourable situations it rarely grows more than 60 feet high, and is usually a gnarled inolegant tree. Nuttall mentions a variety of this species as occurring a few miles from Philadelphia, with 'fruit nearly twice the ordinary size, as large as an apple.'

5. *Carya microcarpa*.—Leaflets about five, oblong-lanceolate, sharply serrate, and obviously tapered to the point; smooth on each side, glandular beneath. Fruit roundish, with a small thin-shelled nut, which is somewhat quadrangular, and abruptly rounded at the end, with a very small nut. According to Nuttall, this is found wild on the banks of the Schuylkill, in the vicinity of Philadelphia, where it is of a large tree with an even bark. The fruit is much some of *C. tomentosa*, and eatable, but very small, not believed the size of a nutmeg. represent the bitter nut, or swamp hickory; found Mary Magdalen in the north, as far as the most the Innocents.—The American Union. In woods near

80 feet high; but in general it is smaller. It is the latest in leafing of all the hickories. The leaflets are 7 to 9 in number, smooth, coarsely and irregularly serrated, long, lanceolate, and more wrinkled than in other species. The fruit is small, roundish, with a thin rind; the nuts are obovate, depressed at the end, with a central projecting point; they have no angles, and are broader than they are long; the shell is thin and brittle, and the kernel so bitter and austere that even squirrels refuse to eat it. This species is easily known in winter by its yellow buds.

7. *Carya aquatica*, found only in the lower parts of the southern states of the American Union, in swamps, and by the side of ditches surrounding rice-fields, along with red maples, deciduous cypresses, and Carolina poplars. It is readily known by its very narrow taper-pointed leaflets, which vary in number from 9 to 11. Its fruit is small, ovate, tuberculated, angular, and placed upon stalks in little clusters. The nuts are bright brown, ovate, angular, but little pointed at either end; they are very thin-shelled, and contain an extremely little kernel. The tree grows from 40 to 50 feet high, and is of much less value than the other species.

8. *Carya porcina*, the pig-nut hickory, or hog-nut. This is most common in the middle states, beginning with Lancaster county, Pennsylvania, in the north. It is one of the largest trees in the United States, growing to the height of 70 or 80 feet, with a diameter of 3 or 4 feet. Its brown shoots and oval very small buds distinguish it in winter. The leaflets are lanceolate, very taper-pointed, regularly serrated, and from 3 to 7 in number; they are quite smooth on each side, and on vigorous shoots in shady places their stalks are violet. The fruit is sessile, and varies in form from pyriform to spherical: its little nuts correspond in this respect with their rind; they are scarcely at all angular, and always rounded at the apex, with a sharp point; their shell is very thick and hard, their kernel sweet but small, and difficult to extract.

9. *Carya myristiciformis*, nutmeg hickory. This is a little brown species, of which Michaux obtained a single branch with about 30 nuts, at Charlestown, from a negro gardener, who procured them in the neighbourhood of that city. Its leaves are like those of *C. aquatica*, but not quite so long and narrow. The fruit is sessile, oval, tuberculated, and contains a small, smooth, brown, striated nut, with an exceedingly thick shell, and a very small kernel. Elliott, who resided near Charlestown, and wrote on the plants of Carolina, could never gain any further intelligence of this plant.

(See Michaux's *Arbres Forestiers de l'Amérique Septentrionale* for further details regarding these trees, most of which are found growing in the plantations of Great Britain.)

CARYATIDES (Καρυάτιδες), female figures employed in architecture in place of columns, like Adantes and Telamones. Vitruvius attributes the origin of Caryatid figures to the circumstance of the inhabitants of Carys, a city of Peloponnesus, taking part with the Persians during the invasion of Xerxes, and their consequent punishment the men were slain, and the women carried into captivity, and their ignominy was perpetuated by the employment of figures, similar to the women of Carys, in place of columns. This absurd story however is hardly worth relating. It has sometimes been conjectured that these figures represent the virgins who celebrated the worship of Diana; but the better opinion probably is, that they represent Athenian virgins carrying on their heads the sacred vessels used in religious ceremonies. The use of Caryatid figures appears to be more ancient than the date of the story told by Vitruvius; like many other forms of art, they were most probably drawn from Egypt.

Six beautiful Caryatid figures were employed in the Pandrosion, one of the buildings on the acropolis of Athens. The northern portico of the Pandrosion had six Ionic columns, four in front, and one on each flank; the southern portico was supported by six Caryatid figures, four in front, and one on each flank. They were placed upon a basement, and supported an enriched entablature. (Stuart's *Athens*, vol. ii., Plates.) One of the figures is now in the British Museum among the Elgin collection. The execution of this figure is very fine: its height is seven feet nine inches.

At the sides of the New Pancras Church, London, and at the east end, are two projecting wings with four Caryatid figures in each. The whole is an imitation of the Pan-

* These figures were measured several individuals which lately in London, but not in circumference, and from 70 to

drosion; but the figures are very ill executed. These excrescences form the entrance to the places of sepulture under the church.

[A Caryatid figure from the Parthenon, now in the Brit. Museum.]

CARYBDEA. [MEDUSA.]

CARYCHIUM. [PLEROCHAILUS.]

CARYOCATACTES. [CORVIDE.]

CARYO'CAR, the only genus of the natural order *Rhizophoraceæ*, one of whose species yields the butter-nuts of the London fruiterers' shops. One species is described by Aublet under the name of *Pekoa butyrosa*, as a large tree with a trunk eighty feet high, and three feet in diameter. The bark is greyish; the wood reddish, hard, and compact. The leaves are opposite, each composed of five leaflets arranged in a palmated manner, the central leaflet being the largest, the two lower the smallest; they are as if articulated with the end of a footstalk seven or eight inches long, hollowed at its summit, but cylindrical otherwise, and a little enlarged at its base; the leaflets are smooth, oval, and pointed, the largest seven inches long by three broad. The flower-buds are inclosed in two great opposite bracts. The flowers grow in large bunches at the extremity of the branches and the twigs; their footstalks are downy. The calyx is fleshy, deeply divided into five leathery concave rounded parts. The corolla has five large white petals. The stamens are very numerous. The berries are covered by a rind two or three lines thick, and consisting internally of a buttery yellowish substance, which melts between the fingers, and which is sometimes used in cooking instead of animal butter. Under the rind lies a stone covered all over with slender stings, which easily separate, and become very troublesome to those who open the stones; within is a kidney shaped kernel, covered with a brownish membrane, and very good to eat; it is commonly served at table. It is called *pekea* by the blacks in the neighbourhood of Oyapoco in French Guiana, where it is much cultivated. The species that furnishes the butter-nuts of the London markets is much like this, but is called *Tata-youba* by the natives of Guiana, and differs in having no stings upon the surface of the stone of its

fruit: this is the *Pekoa tuberculosa* of Aublet; the *Caryocar domingense* of modern botanists.

Another species, the *Caryocar nuciferum*, bears what are called the *Sawarow* or more properly *Saouari* nuts of commerce. It has only three leaflets to each leaf, each with a toothed margin, and a taper-pointed extremity; the flowers are very large, deep brown externally, and rich crimson in the inside; the fruit is in form like an egg, covered with a thick rough brown rind, beneath which is a soft greenish buttery substance. The nut has a stinging surface, and contains a very excellent kernel, from which may be extracted an oil like that from sweet almonds. All these plants are figured in Aublet's *Plantes de la Guiane Française*. The last is represented in the *Botanical Magazine*, vol. liv.; but there appears to be some confusion in the account there given of the plant.

CARYOCRINITES. [CRINOIDEA.]

CARYOPHYLLEÆ, a natural order of plants, the type of which may be considered the *Dianthus caryophyllus*, or common garden pink. It consists of plants having narrow, opposite, undivided leaves, arising from tumours at the articulations of the stem; flowers with a definite number of hypogynous stamens; a fruit with a central placenta, and seeds that usually have the embryo rolled round mealy albumen. The species are in many cases mere weeds, in no instances have they properties of any importance, being mostly inert; but are occasionally objects of cultivation on account of their pretty flowers, as is the case in the whole genus *Dianthus*, and in several species of *Silene*, *Agrostemma*, *Lychnis* and *Saponaria*. The order has always been divided into two parts, one of which has the sepals combined into a tube, and the other the sepals wholly distinct: these are now considered distinct natural orders, the former constituting *Sileneaceæ*; the latter *Alsiniaceæ*. Of these the last-mentioned is very near *Illecebreaceæ*, and formerly contained species that are now known to belong to that order.

[*Lychnis grandiflora*.]

1, unexpanded flower; 2, calyx; 3, pistil and stamens; 4, a petal, with stamen attached; 5, anther impregnated; 6, a back view of the same; 7, fruit, with calyx remaining after impregnation; 8, the same without the calyx, and as it opens when mature; 9, the same cut horizontally.

CARYOPHYLLIA (zoology), a genus of corals of the section *Madrephyllia* of De Blainville. [MADREPHYLLIA.]

CARYOPHYLLUS AROMATICUS, the clove-tree (in botany), is an evergreen small tree, belonging to the natural order *Myrtaceæ*, with opposite, ovate-lanceolate, shining, leathery, stalked leaves, and a short terminal cluster

of flowers. The flower-stalks are green; the calyx consists of a brownish-red cylindrical tube, terminated by four ovate teeth; there are four small greenish concave petals, and a large cluster of yellow stamens. The fruit is an oblong one-seeded purple berry, crowned by the persistent teeth of the calyx. All the parts are, as in other true myrtaceous plants, covered with dots containing the essential oil peculiar to the species. The clove is a native of the Moluccas, whence it has been carried to all the other tropical parts of the world. Captain Owen's people found it apparently wild even upon Fernando Po, whether it had been probably transported by the Portuguese. The cloves of the spice shops are the flower-buds of this plant, gathered before they open, and dried in the sun; the round ball at their ends is the corolla inclosing the stamens; the quadrangular part below is the tube of the calyx; and the four teeth are the divisions of the calyx. The name *clove* is a corruption of the French word *clou*, a nail, a name that has been suggested by the resemblance of the dried clove to such a thing. The aromatic stimulating effects of cloves are well known. For a good account of their introduction to Europe, consumption, &c., see 'Botanical Magazine,' vol. liv., t. 2750. By some modern botanists, the genus *Caryophyllus* is reduced to *Eugenia*.

[*Caryophyllus aromaticus*.]

The *Caryophyllus Aromaticus* grows naturally in New Guinea and the Molucca islands, from which last exclusively Europe was supplied for a long time. About 1769 the French introduced it into the Isle of France, of Bourbon, and the Sechelles, and in 1771 into Guiana. In 1798 the cultivation of this tree was extended to Sumatra, and very lately it has been introduced into Brazil. A tree twelve years old will yield from 5 to 20 pounds of cloves annually; when older it may yield about 60 pounds, after which the quantity again diminishes. But as a single stem may live 150 years, it may furnish during that time 1100 pounds of cloves. Each clove is about half an inch in length. The external colour is dark brown, appearing as if covered with dust or little warts, with a somewhat fatty coating. When broken across, the appearance is decidedly oily, and oil quickly exudes from the exposed broken surfaces. The odour is strong and peculiar, but agreeable: the taste aromatic and burning.

Several varieties of cloves are found in the market. The difference of colour is attributed to the different season of the year when the gathering was made. 1st. Soft cloves, called also the Dutch Company's cloves: these have generally been distilled once, and have but a faint odour and taste. 2nd. Dry cloves, which are mostly distinguished according to their place of growth. The English Com-

pany's cloves, which are the finest sort, are of a large size, and of a bright reddish-brown colour. The Amboyna are probably the soft Dutch cloves. The Bourbon cloves are small: those of Guiana are still smaller: these two last named sorts are chiefly used to mix with the former and finer kinds. Analyzed by Trommsdorff, 1000 parts yielded of

Volatile oil	180 parts
Scarcely soluble extractive	40
Gum	130
Resin	60
Tannin	130
Lignine	280
Water	180

By distillation a thickish oil is obtained, which is at first colourless, but by time becomes yellow and brown. Its odour partakes strongly of that of cloves: its taste is very fiery and aromatic: it re-acts as an acid. In time there separates from it a steropten or clove-camphor, called *caryophyllin*. This principle may be procured in great quantity from the English Company's cloves, more sparingly from the Bourbon and Cayenne cloves: in some it appears to be altogether wanting. Owing to the presence of so much oil, cloves cannot be powdered without adding some gum or sugar during the process.

Cloves are employed in medicine, and also more extensively for culinary purposes. When received into the stomach they are powerfully stimulant, and promote digestion when taken along with food which is insipid or difficult of digestion. Though the action is generally limited to the stomach, yet if taken in excess, or the use very long continued, it extends to the brain, causing giddiness and other inconveniences. Cloves may be given in powder, along with gum, in very moderate doses; but the infusion is a preferable form. Either alone, or when made the vehicle for carbonate of ammonia, nothing so effectually and safely removes that feeling of coldness and weight about the stomach experienced by hysterical or gouty persons, and renders it unnecessary to have recourse to alcoholic stimulants, such as brandy, which is too frequently employed under such circumstances. Oil of cloves is used to drop into decayed teeth, and also is given along with many purgative and other medicines to correct their griping tendencies.

The fruit of the clove, called the mother clove, possesses little odour or acrimony; but when preserved with sugar it forms a good condiment to be eaten at dessert by persons with weak digestion. What is called the royal clove is merely a monstrous variety of that above described.

The buds of the *Calyptanthus aromatica* are employed in Brazil as a substitute for those of the *Caryophyllus aromaticus*.

CARYOTA, a genus of palms, with pinnated leaves and wedge-shaped leaflets, strongly toothed at the extremity. It has monœcious polyandrous flowers, a somewhat peltate stigma, and a one or two seeded pulpy fruit, with the embryo near the point of the albumen. The best known species, *Caryota urens*, is a native of most of the tropical parts of Asia, especially in mountainous situations, where, according to Roxburgh, it grows to be one of the largest of the palm tribe. Its trunk is described as being 60 feet high, thick in proportion, and slightly marked with annular scars, produced by the fall of its leaves; its wood is so hard as to be cut with some difficulty, and is consequently of considerable value, provided the soft sap-wood in the centre is scraped away. Its leaves are pinnate, the leaflets obliquely triangular, the apex of the triangle being the point where they are attached to the stalk; their end is irregularly toothed, as if bitten or gnawed by an animal (technically *præmorse*); and their general appearance is on this account so remarkable that Rumpf compares them not inaptly to the fin of a fish. The mass of flowers (*spadix*) is said to be from 6 to 16 feet long, divided into many simple branches, which are pretty thickly covered with innumerable sessile flowers. The fruit is called a berry, one-celled, roundish, about the size of a plum, with a thin yellow rind, so acrid that it produces a severe sensation of burning if applied to the skin; and hence its name, *urens*. It is generally stated, apparently upon the authority of Rumpf, that this noble species of palm yields no sap fit for manufacture into wine, and that the sago obtained from the soft central part of its stem is of such inferior quality as only to be employed in times of famine. Roxburgh however gives a very different account of it. He says, 'This tree is highly valuable to the

[*Caryota urens*.][*Caryota urens*. A portion of the spadix.]

natives of the countries where it grows in plenty; it yields them, during the hot season, an immense quantity of toddy, or palm wine. I have been informed that the best trees will yield at the rate of one hundred pints in the twenty-four hours. The pith, or farinaceous part, of the trunk of old trees is said to be equal to the best sago; the natives make it into bread, and boil it into thick gruel. I have reason to believe this substance to be highly nutritious; I

have eaten the gruel, and think it fully as palatable as that obtained from the Malay countries. This remarkable tree is not uncommon in hot-houses where palms are cultivated.

CASALE, a province and town of the continental Sardinian States. The province is bounded to the N. and E. by the Po, which divides it from the provinces of Verceelli and Mortara, on the S. it borders on the province of Alessandria, and on the W. on the provinces of Asti and Turin. The province of Casale formed part of the former Marquisate of Monferrato. It is intersected from N.W. to S.E. by a ridge of hills which divide the valley of the Tanaro from that of the Po, and are known by the name of the hills of Monferrato. The vine thrives on this tract, which produces some of the best wine in Piedmont. It is also known for its truffles. A great quantity of sheep are reared in the province. Silk is another of its chief products. The population of the province is 102,000, divided among 73 communes. (Serriatori, *Saggio Statistico*.) The chief town, Casale, has 15,000 inhabitants, a considerable number of whom are Jews. It is situated on the right or S. bank of the Po, is fortified, and has an old castle which was once the residence of the marquises of Monferrato. The town has sustained several sieges. The cathedral has a chapel cased with costly marble; the church of Santa Caterina is rich in paintings, and that of the Dominicans is also worth seeing. Casale has several palaces belonging to the nobility, a theatre, and a royal college, besides a college for boarders kept by the fathers Somaschi. There are several manufacturies for spinning silk, and a considerable trade is carried on in corn, wine, and other agricultural produce. Casale is a bishop's see and the residence of the intendente or governor of the province, and has a Tribunale di Prefettura, or court of justice, from which appeals lie to the senate or supreme court of Turin. The town of Moncalvo, with 3700 inhabitants, is next to Casale in importance, and was the birthplace of the painter Caccia, several of whose paintings are seen in the church and convent of St. Francis. The town of Casale is 35 miles E. of Turin and 18 N.N.W. of Alessandria.

CASALE is the name of several other towns in Italy, the names of which begin with the word casale, which is derived from casa 'a house,' and meant originally a collection of houses. Such are: Casalmaggiore in the province of Cremona in Lombardy, Casal Pusterlengo in the province of Lodi, Casalmuovo in Calabria, &c.

The villages, some of them very large, in the islands of Malta and Gozo, are also called Casali. [MALTA.]

CASAN, one of the five lieutenancies or provinces, into which the former kingdom of Casan is now subdivided, forms a portion of Asiatic Russia, and adjoins the province of Nishni-Novgorod, in Western Russia in Europe. It lies between 55° and 57° N. lat. and 46° and 52° E. long. The surface is in general an undulating level, the south-eastern part of which is varied by the western branches of the Ural mountains, while a small range of limestone hills, called the Undarian Mountains, runs parallel with the right bank of the Volga, but nowhere attains a greater elevation than 1000 feet. Its area is estimated at about 23,600 square miles, and its population, which was about 840,000 at the close of the last century, has increased to about 1,028,000, of whom 474,000 are Russians, Poles, and Cossacks, 245,000 Tartars, 235,000 Tshuwashes, 56,000 Circassians, (Tsheremisses,) and 18,000 Mordwines and others. It is divided into 12 circles.

The principal river in Casan is the Volga, which enters it from N. Novgorod in the north-west, runs through the heart of the province, where it is increased by the large river Kama, and quits it in the south, on the borders of the province of Simbirsk. The Volga has considerable breadth before the Kama joins it, but is enlarged to 2400 feet by the accession of that stream. The Verluga, the larger and lesser Kokshaya, Sviaya, Tsyvil, and Kasanka contribute also to augment the Volga in this quarter. The province is full of small lakes, which as well as the rivers are well stocked with fish. In the Undarian mountains many sulphurous springs and much liquid naphtha are found.

The climate is on the whole salubrious; but the winter is so severe that the rivers are covered with ice from November to the end of March. The Volga, on the breaking up of the ice, rises above seven feet beyond its level in summer. The fruits of Western Europe ripen in the open air.

Agriculture is pursued to a limited extent; and a sufficient quantity of hemp, fruit, and vegetables is grown for ordinary consumption. Indeed, the soil is generally fertile,

but hands are wanting for its proper cultivation. Whole districts are occupied by forests and swamps; the chief kinds of trees are the pine, fir, and oak; and the woods abound in bears, wolves, and feathered game. Large herds and flocks are reared on the rich pasture-grounds which border the rivers; and the fleeces of Casan are of good quality. The Tartar inhabitants make much wax and honey. The province contains stone for building, chalk and lime, alabaster, saltpetre, and small quantities of iron and copper.

The inhabitants are engaged generally in spinning and weaving, tanning, turning and making articles of wood, and oil-crushing, for which last purpose they employ hemp-seed as well as nuts, of which large quantities are obtained, particularly in the districts that lie between Casan and Simbirsk. The province contained, in 1808, 247 manufactories.

The Russian part of the population have preserved their mode of life; the Tartars live either in the towns, where they inhabit a particular slobode or quarter, or in the villages. The Circassians, Tshirwashes, &c. dwell either in the villages or occupy detached farms or settlements, and are by no means distinguished for their cleanly habits.

In 1810 the income of the province was 5,156,772 roubles, (about 236,360*l.*) and the expenditure 483,336 roubles, (about 22,150*l.*)

Casan was in earlier ages subject to Tartar sovereigns; it was conquered by Ivan II. and fell under the Russian sceptre in the year 1552.

CASAN, the capital of the province, is an ancient Tartar town, which stands on a hill rising out of a low plain, between the Casanka and the Bulak which flows into it, and about five miles above the influx of the Casanka into the Volga. It is composed of the Kremlin or citadel, the middle town, and the lower town; the whole is encircled by gardens, fields, and meadows, which, when the Casanka is swollen by the waters of the Volga in the spring, are subject, as well as the lower town, to very heavy inundations. The Kremlin, which is on the banks of the Casanka, contains the governor's palace and archiepiscopal residence, barracks, prisons, and houses of correction, but particularly the highly venerated 'Karsianskaya Boyeniatser,' or cathedral of the Holy Virgin of Casan, the prototype of other Greek churches in various parts of Russia. The middle town is chiefly distinguished by the Gostini-Dver or Bazaar, and the market-place which is surrounded in most parts by lofty houses, chiefly built of stone, and planted with rows of trees. Several of the churches are well built. The lower town, next to the Bulak, contains a number of rows of houses, separated by gardens, which are the residence of the merchants and dealers; and also the university buildings, a handsome pile embellished with Corinthian columns, and containing a library, a cabinet rich in Russian and Tartar coins, collections in Natural History and for experimental philosophy, a botanical garden, and a well-furnished observatory. Casan has 4 squares or open spaces, 33 streets, 41 Greek churches, 4 monasteries, and 8 Tartar medshets or places of worship; a Greek seminary for divinity students, 2 gymnasia and 4 other public schools, 9 Tartar schools, a military school for 330 boys, an orphan asylum and a Russian and a Tartar printing-house. From the towniness of its situation the town is unhealthy, and there is also a want of good water for drinking. The surrounding country produces all kinds of grain, potatoes, pease, and vegetables, in abundance, and the fisheries of the Volga furnish the place with an abundant supply of fish. In 1820, Cochrane stated the population to consist of 40,000, inclusive of 12,000 Tartars. Casan is the seat of several manufactures, particularly woollens, cottons, morocco and other leather; soap, steel, ironware, earthenware, tiles, gunpowder, spirits, and beer. It is the great mart for the products of the adjacent parts, and carries on an extensive trade, of which teas and Asiatic manufactures are leading articles. The Tartars live as a distinct community from the Russians, and have settled on the opposite bank of the Bulak, upon the eminences around Lake Kaban; their dwellings are small and rude. Casan came into the possession of the Russians in the year 1552, when the Czar John Vasilevitch captured it after a siege of 43 days. The jurisdiction of the university extends over 16 circles. (Cochrane and Holman.)

CASAS, BARTHOLOME DE LAS, was born at Seville of a noble family in 1474. When he was about 20 he studied his father, who embarked with Colombo in his

second voyage to the West Indies. On his return to Spain he entered holy orders and became curate of a parish. After some years he went back to Hispaniola, where he found the Indian population cruelly oppressed by the Spaniards. By the system of repartimientos, enacted by order of King Ferdinand of Aragon, and enforced by the governor Albuquerque, the unfortunate natives were distributed like cattle into lots of so many hundred heads each, and sold to the highest bidders, or given away to courtiers and other men of rank in Spain, who by their agents sold them to the colonists. The mortality became so great among these unhappy beings, who were naturally of a weak constitution, that out of 60,000 Indians, who were on the island of Hispaniola in 1508, only 14,000 remained in 1516. The Dominican friars were the only persons who loudly disapproved of this system; the secular clergy and even the Franciscans took part with the colonists. Las Casas sided with the Dominicans, and finding that Albuquerque was deaf to all their remonstrances, he sailed for Spain, asked and obtained an audience of Ferdinand, to whom he made such a dreadful picture of the fatal effects of the repartimientos, that the king's conscience became alarmed and he promised Las Casas that he would remedy the abuse. But Ferdinand died soon after, and Charles I., commonly called Charles V., succeeded him. The minister Ximenes, who governed Spain in the absence of the young king, listened with favour to Las Casas' remonstrances, and appointed three superintendents from among the Hieronymites, an order which enjoyed great consideration in Spain, with instructions to proceed to the West Indies, and examine the matter on the spot, and with full authority to decide finally upon the great question of the freedom or slavery of the Indians. He sent with them a jurist of the name of Zuazo, who had a great reputation for learning and probity, and, lastly, he added Las Casas to the commission with the title of 'Protector of the Indians.' The commission proceeded to Hispaniola in 1517. After listening to the statements of both parties, colonists and Dominicans, or friends of the Indians, and having also examined the physical and intellectual condition of the natives themselves, the Hieronymites came to the conclusion that the Indians would not work unless obliged to do so; that their mental capacities were much lower than those of Europeans, and could not be stimulated to exertion or be made to follow any moral or religious rules, except by authority; and therefore they decided that the system of repartimientos must continue for the present at least, but at the same time they enforced strict regulations as to the manner in which the Indians should be treated by their masters, in order to prevent as much as possible any abuse of power on the part of the latter. Las Casas, not satisfied with this decision, set off again for Spain to appeal to Charles V. himself, who came about that time from Flanders to visit his Spanish dominions. The question was discussed in the king's council, and as the difficulty of cultivating the colonies without the repartimientos was the great objection, Las Casas, it is said, observed that the African blacks, who were already imported into the West Indies, were a much stronger race than the Indians, and might make a good substitute. This suggestion has been made, by most writers on American affairs, a ground of reproach against the memory of Las Casas. It ought to be observed however that the fact of the suggestion rests solely upon the authority of Herrera, who wrote 30 years after the death of Las Casas. The writers contemporary with Las Casas, and Sepulveda himself, his determined antagonist, are silent upon this point. (Grégoire, *Apologie de B. de Las Casas*, in the iv. vol. of the 'Memoirs of Moral and Political Sciences of the French Institute.') It is certain, and both Herrera, and after him Robertson, acknowledge it, that, as early as 1503, negro slaves had been imported into America; and that, in 1511, a large importation took place by king Ferdinand's authorization. The Portuguese seem to have been the first Europeans who traded in black slaves. A negro was found to do as much work as four Indians. Charles V. granted a licence to one of his Flemish courtiers to import 4000 blacks into the West Indies. The courtier sold his licence to some Genoese speculators for 25,000 ducats, and the Genoese then began to organize a regular slave-trade between Africa and the New World. But the price of the blacks was so high, that few of the colonists could avail themselves of this supply, and consequently the slavery of the Indians was perpetuated for a long time after, until the extinction of most of the islands.

of all the universities in her kingdom. At the Restoration he was restored to all his ecclesiastical preferments, and continued to employ himself in writing till his death, 14th July, 1671. He was buried in Canterbury Cathedral. He had several children by his wife, whom he married in 1651, and who brought him a good fortune. His son John was a surgeon at Canterbury. His works, though numerous, are not of great value. In his book on 'Credulity and Incredulity' (London, 1668, 8vo.; second part, London, 1670, 8vo.) he maintained the existence of witches and familiar spirits.

CASBIN, otherwise written Casvin or Kazvin, a city of Irak in Persia, which Kinneir, after the observations of M. Beauchamp, places in 36° 12' N. lat., and 49° 33' E. long. It was built about the middle of the fourth century by Shapoor Zoelactaf. Under the princes of the Sufside dynasty Casbin became the capital of the kingdom, and remained such until Shah Abbas removed the seat of government to Ispahan. Although now of diminished importance, it may still be considered a flourishing place, and maintains its rank in the first class of Persian cities. When Morier was there in 1809 a great part of the town was in ruins, occasioned by an earthquake—a calamity to which all the towns at the foot of the Elburz mountains are liable. But when the present writer visited the place in 1832, there was much appearance of recent building, and new buildings were still in progress, exhibiting a principle of revival which is not often exemplified in Persia. The town is situated in an extensive valley or plain upwards of twenty miles in breadth, called the Plain of Casbin. This plain affords good pasturage, contains an unusual proportion of villages, and is in parts well cultivated. The great want in this district is that of water; but an extensive system of irrigation by means of subterraneous aqueducts called *kanauts*, so common in this country, with the natural fertility of the soil, renders the vicinity of Casbin one of the most productive districts in Persia. The town is approached through a vast extent of vineyards and orchards inclosed by high walls. The grapes of Casbin are considered the best in Persia; and its pistachio nuts also are abundant and highly esteemed. The town itself is inclosed by a mud wall with towers, but without any ditch. In extent it is said to exceed Teheran, the capital, but its population is less. The old traveller Herbert, who gives a good and sober account of Casbin in its best days, estimated the population at 200,000; but the vizier of the governor, who seemed well informed in the local statistics, told Morier in 1812, that the males then amounted to 25,000, without counting women and children. As the population would not seem to have decreased since then, we are strongly persuaded that this estimate is much too high; but we possess no materials for correcting the statement. Velvets, brocades, and a coarse cotton cloth, called *kerbas*, are manufactured at Casbin; and the place has also a considerable traffic with the province of Ghilan, on the Caspian. On account of the great proportion of new buildings, the town looks fresh and neat compared with many others in Persia. Some of the mosques and other buildings are good, but there are none that claim particular notice. Any grandeur or magnificence which Casbin may once have possessed has been destroyed by repeated earthquakes, which have left little remaining of the more ancient structures but broken masses of domes, towers, and old walls. A ruined mosque, with a conspicuous dome, and the palace built by the Sufside princes, are the most remarkable remains. The palace, although surrounded with ruins, and for the most part abandoned, still serves as the residence of the prince-governor.

CASCARILLA, a name given by the Spanish Americans to all kinds of tonic barks, and especially in Peru to the different kinds of Cinchona; but in England this word is confined to one kind of bark, imported from the equinoctial parts of America, and used medicinally as a valuable aromatic and tonic. It arrives in Europe in short, thin, brittle fells, whence its name, *Cascara*, bark; *Cascarilla*, little bark. It is said to be received from Paraguay as well as the West India Islands: botanists have ascertained that it is furnished by certain species of the genus *Croton*, particularly by *C. Cascarilla* and *Eleutheria*. [*CROTON*.]

CASE (in Grammar). [*ABLATIVE CASE*.]

CASE, ACTION UPON THE, is one of the forms of action into which, by the common law of England, remedies for civil injuries are distributed. It derives its name from

the circumstance that in the old form of the writ or process, which formed the commencement of the suit, the particulars of the wrong complained of, or the case, were set out in detail with nearly the same precision as in a declaration. [*READING*.]

CASE-SHOT are bullets contained in a cylindrical canister, or in a spherical shell of iron, which are discharged from a piece of ordnance. The first of these kinds of case burst immediately on leaving the gun; and the bullets, which at first take diverging rectilinear directions, soon lose all regularity of motion; and though they do great execution among the troops of an enemy within the limits of their effective range, that range, which does not exceed 500 yards, is in general of too small an extent. The divergency of the balls is said to be less when they are put into the case in tiers than when thrown in at random; and it is further lessened when the bottom of the case is formed of a strong plate of iron.

The spherical case-shot (the second kind above mentioned), which were formerly called Shrapnell's shells from the name of the inventor, are fired like common shells, and the length of the fuse being properly regulated, they only burst at the required spot; consequently the scattered balls and the fragments of the shell may be made to take full effect in a column of an enemy's troops at 800 or 1200 yards distance.

CASEIC ACID. [*CHEESE*.]

CASEMATE, a vault of stone or brick-work generally built in the thickness of the rampart of a fortress for the reception of artillery which is to fire through embrasures pierced for the purpose in the front of the vault.

The smallness of the flanks in the antient bastions, and consequently the insufficiency of the fire from their parapets, gave rise to the invention of casemates which, being formed under those parapets, augmented the means of defending the ditches without rendering any change necessary in the size of the works. Casemates so situated exist in the flanks of the Tower bastions, in places fortified according to the second system of Vauban; and at New Brisach they are formed both in the flanks of the bastions and in those of the intermediate curtain.

Buildings of this nature appear to have been executed as early as the sixteenth century, for they are mentioned by the Italian engineers of that age; and, as it was foreseen that the smoke arising from the discharge of artillery in the vaults might, after a short time, render them untenable, Castriotto recommended that only cross-bows or engines for throwing stones should be used in them.

In the works of Vauban casemates have also been constructed under the parapets in the flanks of the ravelins and of their reduits, for the purpose of defending the ditch and of co-operating with the flanks of the bastions in opposing the construction of the besieger's counter-battery whose situation is indicated at H. [*Fig. 1, BASTION*.]

Besides the supposed inconvenience on account of the smoke, casemates in such situations, their front walls being unavoidably weakened by being pierced with embrasures, are liable to be destroyed in a short time by the direct fire from the counter-batteries, when the roofs, in falling, may bring down with them the parapet above. To avoid this evil, engineers have proposed that the casemates in the flank of a bastion should be covered by the tenaille [*Fig. 1, BASTION*]; in which case a fire of shells is to be directed over the tenaille when it is intended to oppose the enemy in the formation of his lodgments.

A difference of opinion has existed concerning the impediment which might be produced by the smoke in the service of the guns; and in the year 1800 an experiment was made by the French engineers in order to determine the question, in the casemates of the Tower bastions at New Brisach, by firing 60 rounds from two pieces in half an hour. Each of these casemates has a perforation in the front wall, above the embrasure, and an ordinary chimney in the wall opposite the front; and during the firing the door between the casemates was kept open. No considerable inconvenience was experienced by the officers who were present; and as the service of guns in casemates so situated can never be required for a longer time, it seems evident that the apprehensions entertained on this subject are without foundation.

Similar experiments have been made in the casemates Riccaoli at Malta, and the smoke went off very clear, besides having an air-hole in the front

are open towards the sea. The casemates proposed were to be built in the flanks of the batteries and in the same manner; and those exhibited in the system of Carnot are entirely open both in front and rear; the mortars or howitzers being masked by a wall over which the line of fire is to be directed.

The term casemate is also applied to the shell-proof vaults of stone or brick constructed in fortresses to protect the troops, provisions, and ammunition. These are usually formed on the fronts which are least exposed to the enemy, and within the masses of the ramparts either of the bastions or curtains in order that they may be sufficiently protected from the effect of shells falling on them; attention should also be paid in constructing them that their interiors be dry and well ventilated. For the latter purpose, they may have perforations in the front walls; and to render them water-proof, the upper surface of the vault is usually covered with cement. That surface is in the form of two inclined planes meeting in a ridge over the crown, and the ridge, as well as the gutter between every two casemates, is covered with lead. Drains are formed in these gutters to carry off the rain; to facilitate the descent of which into them, courses of dry bricks or beds of gravel are laid on the exteriors of the vaults; over these is a covering of clay and earth terminating above in a level surface. (Colonel Pasley's *Elementary Fortification*, vol. ii. p. 367.) It was from the humidity as well as from the crowded state of the casemates at St. Philip's Fort in Minorca, and the consequent sickness among the troops, that the governor of that post was compelled to surrender it when it was besieged by the Spaniards in 1782.

When casemates are built for troops they should be 16 feet wide, in order to allow room for a double row of beds with a passage along the middle; and on the hances of the vault (the weakest part) the brick work should be about three feet thick. Those at Gibraltar are from 16 to 18 feet wide in the interior, and 16 feet high from the floor to the crown of the arch, which is semicircular, and they are from 40 to 100 feet long; some of them have air-holes in front, with chimneys through the roof, and the back walls have doors and windows which may be kept open while the firing is continued. The vaults of the casemates on the western heights at Dover are parabolical; the whole interior height is 17 feet, the breadth 18 feet, and the rise of the curve is nine feet from the springing courses.

CASHEL, an ecclesiastical province of Ireland, comprising the dioceses of Cashel, Emly, Limerick, Ardfer, and Aghadoc, Waterford, Lismore, Cork, Ross, Cloyne, Killaloe and Kilsenora; a district very nearly co-extensive with the civil province of Munster. By the first Report of the Commissioners of Public Instruction (1834), it appears that the province contains 810 parishes, with a population of 2,336,472, of whom 111,818 are members of the Established Church; 2,220,310 are Roman Catholics; 966 are Presbyterians; and 2454 are Protestant dissenters of other denominations. The number of churches in the province is as follows: churches of the Establishment, 362; other places of worship in connection therewith, 80; Roman Catholics do. 634; Presbyterians do. 20; remains for other denominations of dissenters, 84; making a total of 1170 places of worship, or 1 to each 2000 of the inhabitants nearly. By the Second Report of the same Commissioners (1835), it appears that there are in this province 2332 schools, educating 161,830 young persons of both sexes, showing a proportion of 1 school to each 1000 of the inhabitants nearly, and of scholars a proportion of 6.4 per cent. to the entire population; in which last ratio Cashel stands lowest of the Irish provinces. Of the above 810 parishes, which, in the Establishment, are divided into 469 benefices, there are 260 without glebes; 368 without any public place of Protestant worship; 200 in which no Protestant worship is performed; 21 in which there is no member of the established church; 68 in which such members do not exceed 20 in each; a total of 170 in which they do not exceed 50 in each; and in no parish of the province do they amount to 5000. (*Parliamentary Reports*.)

CASHEL, an archdiocese and city of Ireland. The diocese was erected into an archbishop's see at a synod held in Drogheda (March, 1159), where Donat O'Lonagan, the first of that name, was invested with the pall by Cardinal. Report of the legate of Pope Eugene III. The see is seated in the king's castle (St. Henry VIII.) at 651, 1583, Irish, at 486, 1813. The chapter consists of

chantor, chanter, treasurer, archdeacon, and five prebendaries; and the diocese, which contains 100 parishes, is divided into 48 benefices and 12 rural deaneries. With the exception of two parishes, the diocese is confined to the county of Tipperary, with which it is very nearly co-extensive. The proportion of Roman Catholics to Protestants of all denominations is as 36 to 1; of schools to entire population as 1 to each 753 nearly; and of scholars to entire population as 9.4 to each 100; in which last ratio this diocese stands first in the province, and is very nearly on a par with the average of the province of Armagh. Of the four Irish archbishops, the Archbishop of Cashel ranks third.

The seat of the see is at Cashel, a very ancient city, situated in the parish of St. Patrick's Rock and barony of Middlethird, in the country of Tipperary, 108 English miles S.W. from Dublin, a few miles E. of the river Suir, which flows southward towards Clonmel, from which town Cashel is distant fourteen miles. The boundaries of the old borough of Cashel included the entire of the ancient walled town, and extended between two and three miles in a south-western direction on the road to Cahier and Clonmel, including an extent of 3912 statute acres. By the late Boundary Act, 2-3 Will. IV., c. 89, the limits of the borough have been enlarged so as to embrace a part of the city which had extended northward beyond the ancient jurisdiction, by which the total area of the borough has been increased to 3974 statute acres, with a gross population of 6971 persons. Cashel sends one member to the imperial parliament.

The town, which is now much decayed, is chiefly built round the southern and eastern sides of an insulated mass of limestone, called the Rock of Cashel. On this rock, which rises abruptly in the midst of a rich plain, and commands an extensive view, formerly stood the residence of the petty kings of Munster. Sir James Ware, who lived so late as 1666, informs us that he has here seen the stone on which those potentates were inaugurated, and where, it is said, they received the tribute of their subordinate toparchs. From the latter circumstance the name of the place has been derived; *cash-iol* being interpreted by some 'the stone of tribute;' but *cash-iol* seems to be an original Celtic word, the same in all respects with the Latinized *castellum*, and the probability is that the place was so called from the castle or dun of the chieftain on its summit. A roll or schedule of the tribute payable here is still preserved; and the enumeration of the different articles of use and luxury which formed the rude substitute for rent is sufficiently curious—arms, clothing, provisions, live stock; and slaves, both male and female, being the dues ordinarily specified.

On the introduction of Christianity among the Irish, in the fifth century, Angus, son of the king of Cashel, was one of Patrick's disciples. From him descended Cormac, son of Cullenan, who became king of Munster and bishop of Cashel about the beginning of the tenth century, and who is generally supposed to have built the very remarkable stone-roofed chapel still standing on the summit of the rock. To him also the building of the adjoining round tower has been ascribed; but neither supposition has been borne out by authentic evidence, and the greater probability is, that the chapel was built by Cormac Mac Carthy, king of Munster and bishop of Cashel, in the eleventh century, while of the round tower (pending the publication of the late prize essay of the Royal Irish Academy on that subject) nothing even probable is known. This much however is certain, that both edifices were built prior to the foundation of the cathedral, which was erected by Donald O'Brien, king of Limerick, immediately before the arrival of the English, towards the latter end of the twelfth century. The cathedral is in the form of a cross, the choir and southern transept embracing Cormac's chapel on two sides: the chapel however, not being built due east and west, stands a little out of line, flanking the southern side of the choir, to which it serves as a chapter-house, and which is interposed between it and the round tower on the northern side. The other buildings on the rock are a hall for the vicars-choral, built by Archbishop Rd. O'Hedian (1421), who also repaired the cathedral, the old episcopal palace at the west end of the cathedral, and the remains of the Abbey of the Rock of Cashel, founded by David Mac Carthy about 1260. A wall, intended for defence, some remains of which were standing at the beginning of the present century, surrounded the platform on which the ruins stand, and

completes the pile of building, which, from its commanding situation, massive proportions, and singular variety of outline, is justly considered the finest of the kind in Ireland. The chapel, which, from its undoubted antiquity, is an object of the highest architectural interest, consists of a nave and choir; the latter of lessened dimensions, and partaking rather of the character of a cell. There is a slender square tower, very similar to that of St. Peter's at Oxford, built in the re-entrant angle of the choir at the south side, and rising considerably above the roof, which is of stone, of a very lofty pitch, springing from corbels, and concentrically vaulted underneath. The upper vault is Gothic, being the only arch of that description in the entire building, and forms the ceiling of an apartment, the floor of which rests on the arch of the lower vault, which is Saxon, and in like manner forms the ceiling of the nave below. This under-arch springs partly from the thickness of the wall, and partly from the architraves of a double range of rudely-carved columns at either side; those of the lower range are square, adorned with a lozenge net-work, and form pedestals to the round columns of the upper tier, which are ornamented with bands and capitals. Outside, the corbels supporting the pedimented roof form the architraves to two similar tiers of pillars at either side, between the columns of the lower of which ranges the windows that light the nave are pierced. The principal dimensions are as follows:—Length of whole building outside, 53ft.; inside, 47ft. 8in.; length of nave, 30ft.; breadth of ditto, 18ft.; length of choir, 13ft. 8in.; breadth of ditto, 11ft. 6in.; height of the roof from ground outside, 52ft.; slant of ditto, 24ft.; mean thickness of the walls, 4ft. 1in.; length of square tower, 10ft.; breadth of ditto, 6ft. 8in.; height of ditto, 68ft. These dimensions are given the more minutely, as Cormac's chapel is by far the most perfect specimen of this description of building in these islands, and as it gives a convincing proof not only of the existence but of the excellence of some works in stone and lime, exclusive of round towers, in Ireland before the coming of the English.

Donat O'Lonargan, the first bishop of Cashel who received the archiepiscopal pall, was succeeded in the see (1152) by Donald O'Hullucan, in whose time (1172) the great synod was held here, which has been so much celebrated by the early historians of the conquest as that at which the Irish prelates are alleged to have recognised the civil authority of the English king and the ecclesiastical superiority of the Anglican church. By this time a town had grown up round the seat of authority, large enough to make its burning in 1179 worthy of mention in the Irish annals. The next archbishop was Donat O'Lonargan the second, who assisted at the council of Lateran (1215), and died there. He was succeeded by his namesake, the third archbishop of the name, who erected the town of Cashel into a borough, in 1223. His successor, Marian O'Brien, having obtained a perpetual alms-gift of the town from King Henry III., re-granted and confirmed the same to the provost and burghesses, reserving only to himself the bakery and shambles (1230), in return for which the citizens made a grant of two gallons out of every brewage of ale in their town, for ever, towards the support of a lazaret-house, founded about this time by David de Latimer, the archbishop's senechal. Marian was succeeded (1253) by David Mac Carwell, who (1268) granted an indulgence of forty days to all such as would contribute to the erection of the church of *St. Paul's*, in London. This prelate, who was somewhat of a turbulent character, forcibly expelled the occupants of the lazaret-house founded by Latimer, and converted it into a monastery of black monks. He was engaged in various disputes with the government, but was a great benefactor to the church; he founded the Chauntry of St. Nicholas, the Abbey of the Rock of Cashel, and Hoar Abbey, a monastery for Cistercian monks, in the vicinity of the town, the ruins of which, still standing, attest its former splendour.

Cashel now seems to have attained considerable importance as a town; for by an assize taken, 7 Edward II., on occasion of a dispute relating to the above-mentioned grant of ale, it appears that there were at that time thirty-eight common brewers, or brewers of ale for sale, in the town. It was however, unfortunately situated in one respect, being upon the borders of the Butlers' country, and exposed in their wars with the family of Desmond to the hostile neighbourhood of the Fitzgeralds. In one of the frequent disputes between these turbulent families, David Creagh, who had become archbishop in 1483, rendered himself by some

means obnoxious to Gerald Fitzgerald, the great Earl of Kildare; the consequence of which was, that Gerald, about 1498, burnt down the cathedral, after probably devastating the town. Creagh, countenanced by the Earl of Ormonde, the chief of the Butlers, laid his complaint before King Henry VII., who, taxing Kildare, then present in council, was answered by the audacious noble, that "By ~~his~~ he would never have thought of committing such a sacrilege, had he not been told for certain that the archbishop was inside." This characteristic reply is said to have gained him the good will of the king, who shortly after created him lord deputy, alleging that "if all Ireland could not govern him" (which was the gist of his rival's complaint), "he was for that very reason the fittest man to govern all Ireland."

There is little of interest in what is known of Cashel Gill shortly after the Reformation, when James Mac Caghwell, who had been nominated to the see by Queen Elizabeth, was stabbed to death by Maurice Gibbon, or Maurice Beagh, his titular rival (1570). His successor was Miles Magrath, who, after having for some time filled the see of Down as titular bishop, embraced the reformed religion, and was advanced to the dignity of archbishop of Cashel by the queen. This see he held from time to time in *commendam* with Lismore, Emly, and Waterford, and died here (1612) aged 100. He is much censured for having alienated a considerable part of the property of the see. By some he is supposed to have died a Roman Catholic. His monument is shown on the south side of the choir, but his body is said to have been privately interred, according to the rites of the Roman Catholic church, elsewhere.

In the wars subsequent to the rebellion of 1641, Cashel was for some time garrisoned, and the rock put in a state of defence by Lord Taaffe, on the part of the Irish royalists; but Lord Inchiquin, who commanded the Irish parliamentary forces, having taken Cahier, which was at that time considered the key to Tipperary (1647), assumed a position so threatening that Lord Taaffe thought it expedient to withdraw from Cashel, leaving only a small garrison to aid the inhabitants in their defence. On Inchiquin's approach the city was deserted, and the people, leaving their gates open, fled to the cathedral, either as a citadel or as a sanctuary. Here they were summoned to surrender; and Inchiquin offered them liberty to depart on condition of their paying 3000*l.*, and furnishing a month's provision for his troops. The terms being refused the place was carried by assault, with a great slaughter of the besieged, of whom above twenty priests and friars were slain before the assailants gained possession of the cathedral, when at length quarter was given, and the survivors suffered to return to their homes. The city was again taken by Cromwell after which its annals afford nothing historically remarkable. In common with every other town of Ireland, Cashel reaped the advantages of the settled state of society consequent on the revolution of 1688, and up to the end of the last century seems to have been a flourishing place.

At present the city is in a state of lamentable decay, which is as much owing to the inefficient constitution of its corporation as to any other cause. The history of the corporation of Cashel furnishes the most striking example to be met with in this country of the evils arising from a corrupt municipal system. Their governing charter was granted 15th Charles I. (in 1640), and created the borough into a city, to be governed by a mayor, aldermen, bailiffs, and commons. This charter was repealed by the 6th James II., which recites a seizure of the franchises of the city into the king's hands by a judgment of the court of Exchequer; but in 1690, King William having his camp at Goldenbridge, not far distant, was memorialized on the subject of their displacement by the mayor and commons, whereupon he gave them a letter restoring them to their ancient rights and privileges as in the time of Charles I. The charter entrusted to this body for the benefit of the city consist of nearly 4000 statute acres of arable land, worth at least 20*s.* per Irish acre per annum; and of which upwards of 1700 Irish acres were out of lease so recently as 1837, yet the rents at present arising out of this great tract of land, which under proper management should produce a sum sufficient for all the purposes intended, amount to no more than 219*l.* 18*s.* 10*d.* per annum. From the Report of the Commissioners on Municipal Corporations in Ireland (inquiry held in November, 1833), it would appear that this very inadequate return has been caused by the disposal of large holdings to members of the corporation at rents which

may be termed a waste, particularly of 1448 acres, 2 rods, 4 poles, which was leased to an individual for ninety-nine years, from the 25th of March, 1830, at a rent of £1000 per annum; the board of aldermen, who made the lease for the lease, consisting of the grantee, two of his sons, seven other of his relatives, and one alderman connected with him by marriage. In consequence of this alienation of the public property, and from the mayor and aldermen having converted to their own uses the tolls and customs of the city, the public works of Cashel have fallen into a state of ruin almost unexampled in the kingdom. The streets are unpaved, unlighted, and uncleaned. There is no supply of water but by pumps repaired at the expense of the county. The water-works, erected in the early part of the last century by Archbishop Bolton, have gone completely to decay; the underground conduits, upwards of two miles in length, are choked up or obliterated, and the stream is diverted to the supply of mills in the neighbourhood. It is estimated that £6000 would be sufficient to supply the city with this most necessary element. There is no corporate police; their place being supplied by county constabulary. There is no institution for the support of the poor, of whom several hundred daily leave the town on begging excursions among the small farmers of the neighbourhood, and return at night to their hovels in the suburbs. The appearance of Cashel fully proves the neglect complained of. Although the main street is broad and handsome, the remainder of the town is mean. Out of 1135 houses, 751 are thatched; 26 are uninhabited, and 190 only are worth 10*l.* and upwards per annum. There is here a pretty good barrack, a dispensary, and a well-regulated bridewell, unconnected with the corporation. The new cathedral, built about the middle of the last century by Archbishop Agar (the old cathedral having been unroofed by Archbishop Price in 1752, and consequently gone to ruin), is a handsome structure, and stands within the town: the organ cost 600*l.*, and is a fine instrument. The archbishop's palace is a respectable mansion with very fine gardens, extending to the foot of the rock.

In 1831, the population of Cashel was, males 3279, females 3692, total 6971—in all 1364 families; of which 511 were chiefly employed in agriculture, 596 in trade, manufactures, and handicraft, and 257 not included in each denomination, but chiefly paupers. The proportion of Roman Catholics to Protestants in Cashel is about 30 to 1. The charter school of Cashel is an extensive and commodious establishment, with an income of 20*l.* per annum, and 22 acres of land annexed. In 1826 there were in Cashel 4 Protestant and 20 Roman Catholic schools, educating 697 males, and 381 females; and in 1833 there were in the entire deanery, which extends considerably beyond the city, 20 schools, of which 2 were in connection with the national board, educating 743 males and 636 females. There is no published history of Cashel.

The local taxes levied here are tolls, corporate customs, and church rate. (Ware's *Works*; Ledwich's *Antiq. of Ireland*; Carter's *Life of Ormonde*; Post-Chaise Companion; Inglis's *Ireland* in 1834; *Parliamentary Reports and Papers*; *MS. in Lib. Roy. Irish Academy*.)

CASHEW-NUT. [ANACARDIUM.]

CASHMERE, the most extensive of the alpine valleys of the Himalaya range, lies embedded in high mountains, between 33° and 35° N. lat., and 74° and 77° E. long. It extends from S.E. to N.W., according to Rennell, between 74 and 75 miles, and its breadth varies from 15 to 36 miles, when the declivities of the mountains are included. In the middle of the valley, near the capital, Sirinagar, there is a level plain some miles in width, which seems to have been once a lake. The waters apparently at last broke down the rocks at the N.W. extremity of the valley, and found their way to the lower plain of the Punjab. This plain is surrounded by high hills, with rather a gentle slope, and covered with large trees and excellent pastures. Behind them rise the mountains far beyond the snow-line, especially in the upper end of the valley. The height of these mountains has not been determined.

Almost innumerable rivulets descend from the sides of the mountains on the margin of the snow-line, and are abundantly filled with water at all seasons. They join, in the centre of the valley, a river, which rises at the

S.E. extremity of the valley. This river, called the Jhyllun, or Behut (the Hydaspes of Alexander), has at Sirinagar, about 60 miles from its source, so much water, that Bernier compares it with the Seine at Paris; and adds that it is navigated by vessels as large as those near the capital of France. Its course through the plain is gentle, and it continues so to the lake of Wuller, issuing from which in a westerly direction, the river enters a hilly country, where it is soon narrowed by steep rocks. It forms several rapids and cataracts, until it reaches Muzzufferabad, a town which belongs to the Punjab. The Jhyllun joins the Chinab (Acesines), and flows into the Indus. The lake Wuller has a circuit of about 40 miles. It is partly surrounded by extensive forests, in which there are numerous wild animals. From these forests the inhabitants get their timber. Near the capital is another lake called Dull, which, though shallow, seems to be of considerable extent; it is divided by dams into several parts, and contains many floating islands.

Numerous canals intersect the plain in every direction, which, besides watering the contiguous lands, afford great facilities to communication, being large and deep enough to be navigated by river barges. Cashmere is noted for the mildness of its climate, on which account it was chosen by the emperors of Delhi for their summer residence; but it appears not to deserve this praise, except in summer, when the heat, though great, is less oppressive than on the banks of the Ganges or Jumna. The winters are of course cold in a valley which is 6000 or 7000 feet above the sea. In 1822 Moorcroft found that snow began to fall in the middle of December, and the plain was not clear of it before the end of March. The sky during the winter months (from December to March) is so cloudy that the sun, on an average, is not seen oftener than once in three or four days, and then only for a short time. Towards the end of March and in April it is more frequently visible, but attended by a rapid succession of gusts of wind with hail. In May, 1823, scarcely a day passed without a shower; and Moorcroft observed, that he never had seen an atmosphere so frequently loaded with moisture. June, July, and August are hot; but the mornings, evenings, and nights are generally cool. Sometimes, though rarely, a failure of the rice crop has been experienced, owing to the summer heat not lasting long enough to ripen the grain. Cashmere produces wheat, barley, buck-wheat, millet, maize, pulse, and rice. Rice is raised in the greatest quantity, and may be considered as the staple. It is grown at a considerable elevation on the declivities of the mountains, as the streams which descend from their sides afford facilities for watering the fields. The lower classes live partly on the singhara, or water-nut, which, during eight or nine months of the year, is fished from the bottom of the lake Wuller. The mucilaginous pith of the water-lily (*Nymphaea lotus*) also supports a considerable number of people during eight months. Turnips, spinach, loose-leaved cabbages, and lettuce of the same description, are raised in the usual way; and cucumbers, gourds, and melons, in great quantities, by the ingenious and simple contrivance of platforms floating on the lakes. These swimming beds are commonly two feet thick, seven broad, and of considerable length. They resemble, in some respect, the swimming beds observed by Humboldt on the lake of Chalco near Mexico, where they are called *chinampas*.

Among the cultivated plants the crocus is the only one which furnishes an article of export, the saffron of Cashmere being known in all parts of western Asia.

The principal fruits are apples, pears, quinces, apricots, plums, cherries, and a nondescript species of grapes, called sungut by the natives. This grape yields, by distillation, a beverage which, in the opinion of the Chinese, is not inferior to that of the grape. Common grapes also abound, and the wine which is made resembles Madeira. Most of these fruit-trees cover large tracts of ground on the declivities of the hills, and have no owners: the fruit is gathered by the lower classes, and often constitutes their principal subsistence. It is thought that they are the remains of gardens which have been deserted.

No trees are cultivated with any care except the walnut, of which there are three different kinds. The kernel is eaten, and used for making oil; and the husks of the fruit are employed in dyeing black. Cashmere is famous for its flowers, especially roses, which are cultivated with care, and

are numerous, and are of a small size, but

Wardy. More attention is paid to black cattle; the breed is not large, but gives abundance of milk. Sheep are very plentiful, and their flesh well flavoured: goats abound in different places. In winter sheep are fed upon the leaves of several trees, which have been dried in the preceding summer.

Neither poisonous nor carnivorous wild animals are said to exist in Cashmere; but the forests abound with some kinds of deer, and the rivers with fish and water-fowl. Bees are very numerous, and each farmer has several bee-hives in the walls of his house, and sometimes as many as ten. These hives are of a cylindrical form, and extend quite through the wall of the house. Silk-worms are reared, but probably less than formerly, when silk was an article of export, which modern travellers do not mention. The metals are iron, which is abundant, but not of good quality; and copper and lead, which are said to exist, but are not worked.

The population of Cashmere is estimated to amount to 600,000. It consists, with few exceptions, of the natives, who appear to be of Hindu origin, though some authors think that the Cashmerians, as well as the Afghans, are descendants of the Jews. Their language, which is evidently derived from the Sanscrit, is pronounced with even more harshness than that of the Maharattas. The Cashmerians are very industrious, which is shown in the excellencies of their cultivation, and the perfection which their manufactures have attained. In this they resemble the Hindus, but they are also very fond of amusements, and ready to expend what they have gained. They are very fond of music. The principal branch of industry is shawl-making, in which 60,000 individuals are employed, though the number of looms, which 200 years ago amounted to 40,000, has been reduced to 16,000. Two weavers work at each loom, when the shawls are simple; but when they are of a superior kind, four persons are required. According to an estimate, 80,000 shawls are annually made. Paper is also manufactured, and though less is now exported than formerly, it is still considered as the best made in western Asia. The Cashmerians work with great skill and taste different objects in wood, which, as well as lacer-work, are exported to the neighbouring countries. The extraction of the attar of roses is also an important branch of industry. The commerce of the country seems to be limited to the exportation of the manufactured goods, and the importation of wool from Tibet, and of metals from India, and perhaps from Persia. The transport of goods over the high mountains is chiefly effected by men, who carry them on their backs. Between Cashmere and Ladak sheep are used to carry burdens.

Srinagar (Sranagara), the capital, contains from 150,000 to 200,000 inhabitants. It is nearly in the centre of the plain, on the N.E. bank of the Jhyllun, and is traversed by two small rivers. The streets are narrow and dirty. The houses are built of wood, and commonly four stories high, and sometimes higher. The ground-floor serves as stables, and for agricultural or other utensils. The family live in the first-floor, and the third and fourth are used as magazines of goods and provisions. The roofs of the houses are covered with tubpan beds. There is no good public building. Islamabad, higher up the river Jhyllun, is also a considerable town, situated on the right bank, where the river becomes navigable for barges.

Sampre, likewise a populous town, is also on the right bank of the Jhyllun, but below, about twelve miles, Srinagar.

Cashmere seems to have formed an independent kingdom up to the thirteenth or fourteenth century, when it was subjected to the Gaznevdes, and afterwards united to the dominions of the emperors of Delhi. When that empire was destroyed, about the middle of the last century, Cashmere was taken by the Afghans, who remained in possession of it till recently, when it became a part of the extensive dominions of the Maharaja Runjoet Sing, the sovereign of the Seikhs. (Borrier; Forster; Moorcroft in *Geographical Journal*.)

CASIMIR. [BIRMAN EMPIRE.]

CASIMIR I., son of Miecislav II., king of Poland, was a minor at his father's death in 1034. His mother Rikacha, niece of the Emperor Otho III., assumed the regency, but the Poles being dissatisfied with her government, she was obliged to fly with her son into Germany, from whence Casimir proceeded to France, where he entered the Bene-

dictine order of Cluni. In 1041 he was recalled by his subjects, who prevailed on the Pope Benedict IX. to absolve him from his vows, upon which he married Maria, sister of Jaroslaw, grand duke of Russia. Casimir defeated the Bohemians, and took Silesia from them. He founded a bishopric at Breslau. He did much to civilize the Poles, and he introduced among them his former brethren the Benedictines of Cluni. After a reign of eighteen years, he died in 1058, and was succeeded by his son Boleslas II., styled 'the Bold.'

CASIMIR II., younger son of Boleslas II., succeeded his brother Miecislav III., who was deposed by the nobles for his tyrannical conduct in 1177. He defeated the Prussians, who were then heathens, and were very troublesome neighbours to the Poles, and he obliged them to adopt the Christian faith. He died in 1194, and was succeeded by his son Lesko V.

CASIMIR III., called 'the Great,' succeeded his father Wladislas in 1333. He conquered the Russians, and annexed the greater part of their country to the crown of Poland; he also defeated the Bohemians. He married Anno, daughter of Gedemin, grand duke of Lithuania, and died in 1370, leaving no issue. In him the male line of Piast, which had held the crown of Poland since 820, became extinct. Lewis, king of Hungary, the son of Casimir's sister, succeeded him on the throne of Poland.

CASIMIR IV. was the second son of Jagello, grand duke of Lithuania, who married Hedwige, daughter of King Lewis, and thus became king of Poland under the name of Wladislas IV. Casimir succeeded to the crowns of Poland and Lithuania after the death of his brother Wladislas V., who lost his life in the battle of Varna against the Ottomans in 1444. Casimir made war against the Teutonic knights, and took from them a great part of Prussia; upon which the grand master of the order acknowledged himself a vassal to the crown of Poland. The duke of Wallachia also about the same time made allegiance to the same crown. It was under Casimir that the deputies of the provinces first appeared at the Diet of the kingdom of Poland. (Puffendorf.) This was the epoch of the greatest splendour of that country. Wladislas, son of Casimir, was made king of Bohemia and of Hungary. Casimir died in 1492, and was succeeded by his second son John Albert. It was Casimir who enforced the use of Latin as the official language of Poland.

CASIMIR V., son of Sigismund III., was elected king of Poland after the death of his brother Wladislas VII. in 1647. Casimir was then at Rome, where he had entered the church, and had become a cardinal. Having obtained a dispensation from the pope, he married Luisa Maria Gonzaga, his brother's widow. He made war against the Cossacks, and against the Russians, with various success. Casimir was attacked by Charles Gustavus, king of Sweden, who overran a great part of Poland, and defeated the Poles in a great battle near Warsaw. By the peace of Oliva in 1660 Poland gave up Livonia to the Swedes, and Smolensk and Kiev to the Russians. Casimir, seeing his subjects dissatisfied, abdicated the crown in 1667. He retired to France, where Louis XIV. gave him the abbacy of St. Germain des Prés, and other benefices. He died at Nevers in 1672. He was the last representative of the house of Jagello.

CASIMARHYNCHOS. [PROCNIA.]

CASPIAN SEA (the *Κάσπια θάλασσα* of the Greek writers) is properly an inland lake, which, in consideration of its waters being salt, must be placed among those lakes which are called steppe lakes. It lies along the boundary-line between Europe and Asia. It extends from its most N. point, near the mouth of the river Ural (47° 20' N. lat.), to its most S. point, which is nearly at an equal distance between the towns of Resht and Asterabad (38° 40'), in a straight line about 740 miles; but a curve drawn through the centre, from its N.E. corner at the mouth of the river Elba Djem to its most southern shores, measures about 900 miles. The general direction of its length is from S. by E. to N. by W., but the northern part is curved to the E., and there forms a bay nearly as wide as the main body of the lake. Here its width from E. to W. is 430 miles, but its average breadth is only about 210. Its most eastern point is the Gulf of Mertwoi Kulfusk, which extends to 54° 10' E. long.: the bay of Kooms on its W. shore reaches to 42° 50'. Taking the length of the sea at 200 miles, and its average breadth only at 200, it covers 18,000 square miles, or nearly the area of Spain, not including Portugal.

The Caspian Sea has very few bays. The most important are the Mertwoi Kultusk, or the Dead Sea, which forms the most eastern corner, and by one of its branches, the Turk Karassu, encloses the peninsula of Manghislack on the E. Farther S., nearly in the middle of the E. shores of the lake, is a smaller lake, called Kooli Deria, which contains bitter water, and is united with the Caspian by an open strait. Still farther S. is Baikal Bay, where the ancient mouth of the Amoo Deria or Oxus is said to have entered. [Oxus.] On the western side is the Bay of Sallan, into which the Koor river disembogues; and farther N. the Bay of Kooma which contains the mouths of the Terek and the Kooma. At the mouth of the Volga, the largest of the rivers falling into the Caspian, there is no bay; the numerous islands formed by the stream project some miles into the sea.

The shores of the Caspian are in general so low and flat, that most parts are inundated when a strong gale from the opposite point blows for a few days. The highest shores are those of the peninsula of Abcheron, which projects on the western side from 40 to 50 miles into the sea; but even here they do not rise to a great height. The S. portion of the sea, from the peninsula of Abcheron to the Bay of Asterabad, the S.E. corner of it, is enclosed by high mountains, from 15 to 30 miles distant from the beach, between which and the water extends a low flat country. The E. shores are very little known, on account of their great sterility, and still more, because they are commonly skirted for 20 or 50 miles inland by a swampy tract, which can only be travelled on in winter when it is frozen. The peninsula of Manghislack forms an exception, having rocky but not high shores. From the Mertwoi Kultusk to the mouth of the Terek, and even to the peninsula of Abcheron, the beach is low, flat, and sandy.

The depth of water is considerable, especially towards the S. extremity, where it attains 600 feet, but towards the N. it is not so deep, owing to numerous sand-banks, which are a great impediment to navigation. In general the depth decreases considerably towards the shores, and in some places by terraces. This circumstance renders large vessels unfit for the navigation of the Caspian. Its waters are not so salt as those of the ocean. According to Gmelin, only 10½ ounces of salt can be extracted from 122 lbs. of water; and he thinks that the saltiness of the Caspian is to that of the Atlantic as 1 to 4.

The navigation of this sea is confined to the countries lying on the W. shores between the mouth of the Volga and the town of Asterabad. The Russians of Astrakhan use brigs from 150 to 200 tons; but the Persians only small vessels, from 50 to 70 tons. The navigation is dangerous, owing to the prevalence of N.W. and S.E. gales, which sometimes blow with great violence for many days together. They raise the surface of the sea from 3½ to 4 feet along the shores on which they blow, and inundate the contiguous low countries to a distance of several miles. The fisheries give employment to the inhabitants of the adjacent countries. Numerous shoals of sturgeons, belugas (*Sturio huso*), sturgelets (*Sturio ruthenus*), salmon, and other fish at certain seasons ascend the rivers, especially the Volga, where such large quantities are taken, that this fishery is thought to be only inferior to that on the banks of Newfoundland. Seals are common, and are taken on some islands and on the E. coast.

Naphtha or petroleum frequently occurs on the shores of this sea. In the peninsula of Abcheron the whole soil seems to be strongly impregnated with it. [BAKU.] It is perhaps found in still greater quantity on the island Naphthalia or Tchilehon, the largest of the islands of the Caspian Sea, situated in the Bay of Balkan.

The Caspian appears to be subject to some extraordinary changes in the level of its surface, which have not yet been completely investigated. The inhabitants of Enzilloz, the port of the town of Resht, assured Colonel Monteith that it rises and falls several feet in periods of nearly thirty years; and Hanway has collected some facts to prove that in his time (1748) it had a much greater depth at several places than when it was navigated by the expedition of Peter the Great. Monteith himself observed in a few years a considerable decrease of its waters. There are no tides on the Caspian. The northern portion of it is, annually covered with ice.

Since the middle of the last century it has been known that the surface of the Caspian Sea is lower than that of the ocean. It was observed, that in Astrakhan

was generally above 30 inches. In 1812 an attempt was made by Engelhardt and Parrot to settle this question by a series of levellings and barometrical measurements. They effected this across the isthmus at two different places near the foot of Mount Caucasus. The result of one of these measurements was, that the Caspian Sea was 54 toises or about 348 feet lower than the Black Sea: the other gave a difference of 47 toises or about 301 feet. Some doubts have arisen respecting the correctness of these measurements; and in the present year (1836) the Russian government has granted the sum of 50,000 silver rubles to the Academy of Sciences for the purpose of ascertaining the truth by new levellings.

Pallas, if we are not mistaken, was the first who maintained that the Caspian Sea at some very remote period covered the extensive plain which lies between the most E. ranges of the Ural Mountains and the Black Sea. He inferred this from the peculiar nature of the soil, which consists of sand, partly unmixed with other kinds of earth, and partly containing a portion of clay loosely mixed with it. There is no grass upon it; and shells frequently occur which are met with in the Caspian Sea. It is also impregnated with salt, and contains a great number of smaller and larger salt lakes, among which that of Elton is the best known, from which large quantities of salt are annually procured. This plain is bounded on the N. by a wall-like ascent, elevated at an average 300 feet above it, which in the peculiar form of its margin, resembles very much that of the coast of the sea. This ascent extends from the S.W. extremity of the Ural Mountains, the Obshatshei Syrt, in a S.W. direction, crosses the Volga below its great bend to the E., and divides the source of the small river Samra (an affluent of the Volga) from that of the Manysh. Hence it runs W., and terminates not far from the confluence of the Manysh with the Don. According to appearances, it is very probable that when the surface of the Caspian Sea was at a higher level, there was a passage along the present course of the Manysh river between the Caucasus and the above indicated ascent, which united the Caspian and the Black Sea. Engelhardt, who determined by a series of levellings, and by barometrical measurements, the difference in the level of the two seas, estimated the source of the Manysh to be only 16 toises, or 102½ feet above the Black Sea, and consequently 450 feet above the Caspian.

It may be supposed that the Sea of Aral once formed a part of the Caspian; for though at present the sandy hills between them rise to the height of several hundred feet, it is not improbable that these heights have been formed by the accumulation of sand brought down by strong E. gales, which are very frequent in these countries. If this is admitted, it is not improbable that there existed a communication between the Caspian and Arctic Seas; for Humboldt, in his 'Fragmens Asiaticques,' has traced out a comparatively narrow low tract of land, which extends on the E. side of the Ural Mountains from the N. part of the Sea of Aral between the rivers Ishim and Irtysh, through the steppe of Baraba, and thence on the W. of the Oby to the swampy coasts of the Arctic Sea. This low ground has not been examined, but is indicated by a continuous series of lakes.

The Caspian was known to the Greeks and Romans. Herodotus (i. 203), the first who mentions it, calls it the Caspian Sea, a name probably derived from the Caspi, who inhabited its southern coast. This name it has preserved, though later writers limited the term Caspian to the W. portion, calling the E. the Hyrcanian Sea. Herodotus gives a pretty just idea of its extent, stating that its greatest width was about one-half of its length; but as Niebuhr has properly remarked (*Dissertation on the Geography of Herodotus*), he does not give any hint as to the direction in which the length and breadth respectively lie. Aristotle (*Meteorologica*, chap. 2) does not differ from the historian in his opinion as to the Caspian lake; but about this time an opinion began to prevail, that the length of the Caspian Sea was in the direction from E. to W. About the same time also it became a general notion that the Caspian was connected with the Arctic Sea by a strait, an opinion which seems to have arisen from some slight information obtained respecting the mouth of the Volga. It was said that the strait was only four stadia wide. Ptolemy, who knew the Volga, which is named by him 'Rha,' does not mention the existence of this strait, though he still thought that the greatest extent of the Caspian was from W. to E. This form of the Caspian is preserved on all our more ancient

maps, up to the beginning of the last century, when Peter the Great sent an expedition to explore the sea. (Pallas; Engelhardt; Humboldt; Col. Monteith, in *London Geogr. Journal*.)

CASSANDER was the son of Antipater, to whom Macedonia was allotted on the division of the Macedonian empire after the death of Alexander. Antipater dying, B.C. 318, appointed Polysperchon to succeed him. [ANTIPATER.] Cassander bore this exclusion with indignation; but finding his party too weak for successful opposition, he fled to Asia, and sought the assistance of Antigonus and Ptolemy. Antigonus gave him 4000 men, with whom he sailed to Athens, and was received by Nicanor, the Macedonian governor of the port and fortress of Munychia, who had recently, by a sudden attack, obtained possession of the chief part of Piræus also. Polysperchon lost no time in conducting an army to besiege him, but was soon obliged, by scarcity of provisions, to draw off the greater part of his troops into Peloponnesus, leaving only an army of observation in Attica. Almost the whole of Peloponnesus favoured Polysperchon; Megalopolis however remained firm to the Cassander, and defended itself with such resolution that the rival was compelled to retreat from under its walls in mortification and disgrace. Parties were so balanced in Greece, that a slight thing was enough to turn the scale in favour of one or the other. Polysperchon falling into disgrace through this failure (says Diodorus, xviii. 74), most of the Greek cities went over to Cassander; and, among the rest, Athens, seeing no chance of recovering possession of its ports by force of arms, B.C. 317.

In the following year, Cassander marched into Macedonia against Polysperchon, who, with the view of strengthening his party among the Macedonians, had associated with himself Olympias, the mother of Alexander. Leaving Callas, his general, to oppose Polysperchon, Cassander himself blockaded Olympias in Pydna during the winter. That town yielded on capitulation early in the year B.C. 315, when Olympias, in express contravention of the terms of surrender, was put to death through his agency. Having now gained possession of Macedonia, with the power, though not the name, of a king, he took to wife Thessalonice, the daughter of Philip and half-sister of Alexander, in hope of confirming his own ascendancy by the powerful associations connected with the royal blood. In the same year he founded the flourishing city of Cassandria, in Pallene, which was formerly known by the name of Potidea, and commenced the restoration of Thebes, twenty years after its destruction by Alexander. Soon after he joined the combination of Ptolemy, Lysimachus, and Seleucus, against Antigonus. The war which ensued was concluded, B.C. 311, on condition, so far as related to Cassander, that he should be military governor (στρατηγός) of Europe, till the son of Roxana by Alexander should attain his majority. This limitation Cassander made of no avail by immediately putting to death both the young prince and his mother, B.C. 309. Polysperchon set up another rival to him, in the person of Hercules, the only surviving son of Alexander by Barsine; but he agreed to put Hercules to death on condition of Peloponnesus being given up to him. Hercules was accordingly murdered, but Polysperchon was not able to take possession of Peloponnesus, which was the stipulated price of his treachery.

No part of history is more complicated, and less interesting, than that which relates to the wars of Alexander's immediate successors. We therefore pass over the constant employment given to Cassander by the confirmed enmity of the Ætolians, and by the disturbances continually fomented in Greece by Antigonus.

During the Rhodian war (ANTIG., p. 103), Cassander regained much influence in Greece, which he had lost by the intrigues of Antigonus and the military successes of his son Demetrius. But after the siege of Rhodes was raised, Demetrius again repaired to Greece, and, in the year 302, became master of the greater part of Peloponnesus. The danger in which Antigonus was involved by the second confederacy of Ptolemy, Seleucus, &c., recalled Demetrius to Asia; and the death of Antigonus at the battle of Ipsus, B.C. 301, removed Cassander's most formidable enemy. From that time forwards, he held secure possession of Macedonia, though Demetrius retained considerable influence in Greece. He died B.C. 296, leaving the character of an ambitious, able, unscrupulous man, of whom the best that

can be said is, that his rivals were no better.

He was succeeded in Macedonia by Philip.

CASSATION, 'the reversal of a judicial sentence, is a French law word, derived from *Cassare*, which, in the barbarous Latin of the lower ages, was synonymous with 'irritum reddere,' 'to annul.' (Ducange.) In the early times of the monarchy, petitions were presented to the various provincial parliaments by appellants from the decisions of the lower courts. The decisions of the parliaments on these petitions were liable to be annulled by lettres d'état issued by the king's council. This however gave rise to abuses, and the chancellor De l'Hôpital limited the use of the lettres d'état. By the order of procedure established under Louis XIV. in 1667, two modes of setting aside the decisions of the parliament were finally adopted; one was by 'requête civile,' which annulled a decision and restored the parties to their previous condition, in consequence of either fraud or legal mistakes being discovered in the proceedings; and the other was by 'cassation,' in consequence of a violation of either the principle or form of the law in the decision of the court. In the latter case the cause was tried anew in a council consisting of the chancellor, the four secretaries of state, the council of state, and the maîtres de requête. The national assembly, in November, 1790, abolished this system, and established a distinct, permanent, and independent court, called Tribunal de Cassation, which afterwards received its full organization under Napoleon, and has ever since continued under the name of Cour de Cassation. It is the highest court of France, and receives appeals from all other courts. It consists of 48 members, who, by the charter of Louis XVIII., are appointed by the king, but retain their places for life. The court has its president, although on certain occasions the keeper of the seals, or minister of justice, has the right of presiding in it. It is divided into three sections: 1°. Section des Requêtes, which examines whether the petitions or appeals are to be received. 2°. Section de Cassation civile, which decides upon appeals in civil cases. 3°. Section de Cassation criminelle, which decides upon appeals in criminal matters. The sections do not decide upon the main question, but only on the competency of the other courts, and the legality of the forms and principle of law by which the case has been already tried. If the law is found to have been violated, the sentence of the inferior court is annulled, and the case is sent to be tried again by another court. If this second court decides the case in the same manner as the first, and a petition against the decision is again laid before the Court of Cassation, then the three sections unite together in order to examine the case anew, and if they find reason to pass a second reversal, the case is sent to be tried before another court. Should this third court decide in the same manner as the other courts, and a petition against the decision be again presented to the Court of Cassation, the court requests a final explanation of the law on the point at issue from the legislature.

The institution of the Court of Cassation has proved highly beneficial to France; it has acted as a watchful guardian of the laws; it has afforded protection to the citizens against the arbitrary acts, and the misjudgments or misconstructions of the other judicial courts of the kingdom. Placed by the nature of its office out of the immediate influence of political passions, it has maintained its high character for strict impartiality throughout all the changes of government and administration. Many of the most distinguished jurists of France are numbered among its members. We can only mention here the names of Henrion de Pansey, who was long president and is known for his juridical works, and Merlin de Douai, who was procureur to the court, and is the author of the '*Répertoire de Jurisprudence*,' 16 vols. 4to.

CASSA'VA, or Manioc, a nutritious scula obtained from the roots of jatropha, or janipha manihot, and some allied species. This plant, belonging to the natural order Euphorbiaceæ, abounds in a highly poisonous juice, very small doses of which produce the most dangerous consequences; it is however of so volatile a nature as to be entirely driven off by heat, and consequently there is no practical difficulty in procuring the nutritious substance in a pure state. In order to effect this the roots are peeled, well washed, and then ground between millstones till they are reduced to the state of paste. This is subjected to pressure for the purpose of depriving it, as far as possible, of the juice; the residue is placed in vessels over a brisk and re-

sugar free, and continuously stirred, until it becomes dry; it then acquires a granular appearance, is gradually cooled, and afterwards packed in barrels, when it may be preserved for a great length of time. Half a pound of this substance daily is said to be sufficient to support a vigorous man. Tapioca is a preparation of Cassava. For the manner of preparing the various substances yielded by the janiapha, see *Ambert's Plantes de la Guinée Française*, vol. ii. Supp. p. 63.

CASSEL, HESSE, ELECTORATE OF. [HESSE CASSEL.]

CASSEL, the capital of the electorate of Hesse Cassel, in the province of Lower Hesse, lies on the Fulda, which is navigable, and over which there is a stone bridge. It is surrounded by walls on every side except that which is bounded by the Drusel. It has 11 large and small gates, and is divided into the Old Town, Upper New Town, and Lower New Town, and the three suburbs of Wilhelmshöhe, Frankfort, and Leipzig. The Old Town is a collection of crooked, narrow streets, which are rendered still darker by the height of the houses, and are not kept clean. Cassel is the great seat of trade and manufactures for the electorate. It contains the spacious square called the Palace Square, which is 900 feet long and commands a prospect of the beautiful valley of the Fulda; the market-place; the Electoral Palace, almost entirely destroyed by fire in 1811, on the site of which stands the new and unfinished residence termed the Kaltenburg; the Renthof, consisting of public offices, the old town-hall, the government buildings, the Stadtau, appropriated to public amusements, the packing-hall, and the furniture-hall, or Möbeln-Kammer. There are likewise St. Martin's Church, with the catacombs beneath it, in which the remains of the sovereigns of Hesse Cassel are deposited; the Lutheran, the Brethren's, and the garrison churches; a synagogue, an orphan asylum, and an hospital; an arsenal, foundry for cannon, a house of correction, and other public establishments. The Upper New Town is the finest quarter of Cassel, and may vie in splendour with any city in Germany. It contains the Friedrichsplatz (or Frederick's Square), 1000 feet in length and 400 in breadth; the boulevards; Charles Square, with the marble statue of the Landgrave Frederick; King's Square, of an oval form, 466 feet in diameter; the Royal Street, nearly a mile long, which passes through the centre of the square, the halls for trading purposes, and other handsome buildings; the barracks; William and Gardes-du-corps Squares; and the street of Bellevue, which overlooks a splendid country. Among other edifices in this quarter are the museum, which is considered the finest structure in the town, and contains an extensive library, collections in numismatics, natural history, antiquities, experimental philosophy, &c., and an observatory; the picture-gallery, the Bellevue Palace, the palaces of the elector, electress, and crown prince and princess, as well as of the Wilhelmshöher Rendant; the electoral stables and riding-house, town-hall, mint, cadet academy, lyceum, a normal and civic school, theatre, the New Town and Roman Catholic churches, an hospital and infirmary, a poor-house, six ranges of barracks, &c. The Lower New Town is the site of the Castell, an ancient structure surrounded by walls and a ditch, for the safe custody of state and military offenders: it contains the Lower New Town Church, a Protestant orphan-asylum, infirmary, lying-in-hospital, house of correction, common prison, &c.

In the Leipzig suburb are an hospital, an infirmary, and a spacious building with laboratories; in the Frankfort suburb, a brewell or house of industry, poultry-hall, &c.; and in the Wilhelmshöher suburb, a large hospital, which was originally designed for barracks for 6000 men. The whole town, including the suburbs and two settlements called the Philippinenhof and Momorade, contains 18 squares, 51 public buildings, 9 churches, comprising the Roman Catholic Chapel, a synagogue, 6 schools, 11 charitable endowments, 24 buildings for military purposes, 6 prisons, and about 27,000 inhabitants, among whom are about 500 Jews.

In 1792 the population, inclusive of the military, was 18,400; but in 1812, when Cassel was the capital of the Kingdom of Westphalia, it was 23,167. Independently of the establishments already mentioned, Cassel possesses an academy of arts, with schools of painting, sculpture, and a society of agriculturists, an agricultural association, a bible society, and a medical college. The manufactures of the town, none of which are on an extensive

scale, consist of silks, cottons, hats, tobacco, earthenware, refined sugars, woollens, gloves, cutlery, &c. Cassel has two large fairs annually, but although it lies on a navigable river, and is centrally situated between the Hanse towns, it is not the seat of any great trade. It abounds with public walks, such as the esplanade next the Palace Square, and boulevards adjoining Frederick's Square; without the town is the Aue or public mall, with marble baths, a handsome villa, a fine orangery, and grounds in which animals and wild fowl are kept; and the villa of Schönfeld in front of the Frankfort suburb, the wood of pines, and several public gardens. Every great road about Cassel has avenues of trees. Cassel is about 81 miles N.E. of Coblenz, 31° 18' N. lat., 9° 30' E. long.

CASSEL. [NORD, DEPARTMENT OF.]

CA'SSIA (from the Greek *κασσία*, *cassia*), a genus of leguminous plants, consisting of a large number of species, chiefly inhabiting the tropical or temperate parts of the world, and including among them the plants that produce the senna leaves of the apothecaries. Cassia belongs to sub-order Casalpinieae of Leguminosae, and is characterized as follows by De Candolle:—Calyx consisting of five sepals which scarcely adhere at their base, but are more or less irregular. Petals five, unequal in size: stamens ten, distinct from each other; the three lowest being the longest, the four intermediate ones shorter and straight, and the three uppermost deformed. Each of the anthers as are perfect open at the point. Ovary stalked, usually curved. Legume variable in form. The species consist of trees, shrubs, or mere herbs; the leaves are simply and abruptly pinnated, and usually bear glands on their stalks. The leaflets are opposite each other. Between 200 and 300 species are described by botanists. We shall only notice those employed in medicine.

1. *Cassia fistula* is a small tree, with large yellow flowers growing in long loose racemes, having the aspect of Laburnum, and is found wild in India and the tropical parts of Africa. It has ovate taper-pointed smooth leaves, in from four to six pairs, and long smooth cylindrical dark brown legumes, containing a quantity of thick pulp, that collects into transverse partitions, which separate the seeds from each other. The leaves, flowers, and pulp of this plant are purgative, but they are not much employed in Europe at the present day.

2. *Cassia acutifolia*, a small under-shrub, with ovate lanceolate sharp-pointed leaflets, yellow flowers in terminal erect racemes, and compressed velvety legumes an inch long and half an inch broad. It is found wild in Egypt, Senaar, and Abyssinia, and forms an important article in the commerce of those countries. It is chiefly sent to Alexandria for shipment, whence it has gained the name of Alexandrian senna among the drug-merchants. It is considered the most valuable of all the sennas.

3. *Cassia obovata*, or Aleppo senna, has obovate very blunt leaflets, and curved pods, with a very slight covering of down. The flowers are pale yellow. It is common in the same countries as the last, and mixed with it in commerce; it however chiefly constitutes the Aleppo senna.

4. *Cassia lanceolata*. Leaflets very narrow and acute; pods plano-compressed, straightish, a little tumid in the middle. Found wild in Arabia, whence it is exported under the name of senna of Mecca. It is a good deal cultivated in India, on which account, and from its being usually shipped for Europe from Indian ports, it has acquired the name of East Indian senna in the market. As a species it appears to differ very little, if at all, from *C. acutifolia*.

Of the different species of Cassia mentioned above, either the pulp or leaves are used in medicine. The pulp of *C. fistula*, called also Cathartocarpus *fistula*, consists chiefly of sugar and gum, with some other principles, and is a mild laxative. It accordingly enters into the composition of the confection of cassia, and the confection of senna or lenitive electuary. These are pleasant-tasted but rather bulky purgatives for children. They are not much used, and the pulp of cassia is chiefly employed to form what is termed essence of coffee. This, when prepared from pulp which has not been kept too long, is mildly cathartic, and a very proper article of diet for persons subject to habitual constipation.

The leaflets of several different species of cassia belonging to the section Senna, constitute the various kinds of senna called senna leaves. In addition to the leaflets, the leaf-stalks and pods are frequently present, especially in the Alexandrian senna, which contains also the leaves and pods

of a tephrosia, and the leaves, but rarely the foliicles, of the *Cynanchum Argemone* (Delile) *C. oleosifolium* (Nectoux), a plant of the tribe of the Apocynaceæ, which possesses deleterious properties. The leaves of this last-named plant constitute two parts in ten of the senna of Alexandria. The Tripoli senna is free from it, as is likewise the Tinnivelly senna, which is now the best and cheapest in the markets of this country, and should always be preferred, as much of the griping tendency of common senna is due to the presence of the argel leaves. The senna leaves met with in the continental markets or shops are frequently adulterated with the leaves and berries of the *Coriaria myrsifolia*, a very poisonous plant.

When free from adulterations, senna furnishes a most valuable purgative medicine; but when impure, its action is accompanied with nausea, griping, and other unpleasant symptoms. It is desirable therefore to free it from impurities before administering it or subjecting it to the action of water to form an infusion.

Senna contains a peculiar principle called *cathartine*, with a fat oil, and a little volatile oil, a colouring principle, mucilage, and malate and tartrate of lime, chlorophylle.

The active or purging principle is yielded to water, both cold and warm, and to alcohol. If the infusion be made with cold water, it never gripes: this method is now much employed to form the concentrated infusions supplied by wholesale chemists and druggists to country practitioners. It requires that the water should stand twenty-four hours on the leaves, which should be kept down with a heavy weight, and the air excluded as thoroughly as possible. The compound infusion of the Edinburgh Pharmacopœia, if made with cold water, is a very good form, and even relished by children. The tincture is almost an unnecessary form, while the powder is objectionable from its bulk and disagreeable taste. Various articles, especially aromatics, are occasionally added to infusions to correct its griping tendencies, or increase its purgative power. The confection is an example of such combinations in a solid state. A carefully prepared extract keeps well, retains the odour and virtue for years, and may be given in moderate-sized boluses or pills.

CASSIA BUDS. The unexpanded flowers, when they have attained about a fourth of their complete size, of a species of *Cinnamomum*, are collected and sold under this name. Much diversity of opinion exists respecting the particular species of *Cassia* which yields this article. Professor C. G. Nees von Esenbeck (who is perhaps the best authority) says it is chiefly *C. aromaticum* (Nees), and partially *C. dulcis* (Nees), *Laurus dulcis* (Roxb.), *Cinnamomum Chinense* (Blume), while Dr. Th. Fr. Ludwig Nees von Esenbeck ascribes it to *Laurus Tamala* (Hamilton Lam, *Trans.*, xiii, p. 556, the *L. Cassia*, Hort. Beng.), and Derbach to the *L. Cubeba Lour.*, which last supposition is at variance with the statement of Louriero (*Flora Cochinchinensis*, p. 310), respecting the action of the berries of that species.

Cassia buds have the appearance of nuts with heads of different sizes and shapes, according to the period of growth when collected. But an artificial process is employed by the Chinese collectors, of pressing the top against a flat, hard body, by which the ovary or fruit is prevented falling out. Externally they are of a dark or greyish brown: the fruit which is within is of a bright brown. The taste and odour resemble cinnamon. By distillation they yield a heavy yellowish-coloured oil. It was at one time supposed that an inferior sort, nearly devoid of taste, which is met with in commerce, was the genuine, which had been previously deprived of its oil; but Martius showed that this was a spurious kind, which is distinguished from the true by having the upper part of the calyx marked by six slits or incisions. It is moreover not so rounded as the true sort, and is furnished with a longer foot-stalk.

The uses of *cassia buds* are the same as those of cinnamon and cloves. [*CARYOPHYLLUS*]

CASSIANUS BASSUS. [*GEOPONICA*]

CASSIDÆ. a genus of Coleopterous insects of the family Cassidiadæ. Technical characters:—Body generally some what oval or orbicular, and sometimes nearly square; thorax semicircular or forming the segment of a circle, the margins in Greece considerably beyond and covering the head; the amblygonites have the margins projecting, and forming, as it were, a kind of shield to the body; mandibles with several teeth; the anterior maxillary lobe as long as the submentum. [*CYCICA*]

CASSIDÆRIA. [*ENTOMOSTOMATA*]

CASSIDIADÆ. each, *Cassidiadæ*, Latreille, a family of Coleopterous insects of the section *Cyclica* of Latreille. The species of this family are distinguished by their having the antennæ rather short, filiform or slightly thickened towards the apex, placed on the anterior part of the head, and almost close together. The legs are short and contractile; the tarsi are flattened, soft, and velvet-like beneath; the penultimate joint bilobed, the lobes completely enclosing the terminal joint; body generally very flat. [*CYCICA*]

CASSIDULUS. [*ECHINODERMATA*]

CASSINI. We have now for the second time to sketch the lives and labours of a family of distinguished men, who, though their contributions to the stock of knowledge do not rival in extent or value those of the Bernoullis, present nevertheless a succession of talent and industry which rarely occurs. From the date of its establishment in 1670, till the time when the revolution destroyed all hereditary privileges, the Observatory of Paris passed from one Cassini to another through four generations, as though it had been transmitted by the law of property.

1. In DOMINIC Cassini was born at Perinaldo, in the district of Nice, June 8, 1625, of a respectable family which came from Siena, of which place a Cardinal Cassini was archbishop in 1426. He was educated by the Jesuits at Genoa, and there are some Latin poems of his in a collection of 1646. He attached himself to mathematics and astronomy, and also, it is said, to astrology, of which he was cured by discovering that a prediction which succeeded had been calculated wrongly. He read the work of Pico di Mirandola against astrologers. In 1641, at the invitation of the Marquis Malvasia, who was building an observatory, he removed to Bologna, and in the university of that place, after the death of Cavalieri, in 1650, he succeeded to the chair of astronomy. He here observed the comet of 1652, on which he published his first work. He made various observations with a gnomon and meridian line constructed in a church at Bologna. In 1657 he was deputed, with another, ambassador to the pope, on a quarrel between Bologna and Ferrara relative to the river Po, and on his return was appointed to the superintendence of the river for the former place. In 1663 he was appointed to repair the works of Fort Urban. He was at this time patronized by Pope Alexander VII., and afterwards by Clement IX. In 1664 he made the first of his more brilliant and useful discoveries, namely, the time of the rotation of Jupiter, which he fixed at 9 hours 56 minutes. Professor Any, by very recent observations, makes it 9h. 55m. 21.3s. He also saw, for the first time, the shadows of the satellites of Jupiter. [*CAMPANI*]. By comparison of his own observations with those of Galileo, he constructed (1665) his tables of the satellites. In 1666-7 he found the rotation of Mars to be 24h. 40m. (it is 24h. 39m. 21.3s.) and in this same year he ascertained that the rotation of Venus, which is difficult to observe on account of her phases, does not differ much from that of Mars (it is 23h. 21m. 7s.). He made the apparent rotation of the sun to be about 27 days, which is very near the truth. These results show considerable skill and assiduity, and made the name of Cassini very well known throughout Europe.

When Colbert founded the Academy of Sciences, in 1666, and at the same time projected an observatory at Paris, he proposed to Cassini to remove into France, and offered him a pension equivalent to his Italian emoluments. Cassini expressed his willingness to comply if the consent of the pope (Clement IX) could be obtained, which was done on condition that Cassini's absence should not last more than two or three years. He arrived at Paris April 4, 1669, and began his duties at the observatory September 14, 1671, where his observations extend from 1671 to 1683. In 1673 the Bolognese government, which had kept all his appointments open, required him to return; but Colbert succeeded in negotiating his continued stay in France, and accordingly in the same year he was naturalized in his new country, and married a French lady. He never returned to Italy, except for a short time in 1695, but remained at the head of the Paris Observatory. In the latter years of his life he was totally blind. He died September 14, 1712, without disease, and only, as Fontenelle remarks, *par la seule nécessité de mourir*. His eldest son was killed at the battle of La Hogue; of his second we shall have to speak as soon as we have completed the present part of our subject. In 1671-2 he discovered the third and fifth satel-

ness of Saturn, and in 1684 the first and second. His position at Bologna led him to more correct solar tables than had been in use, and to more exact values of the refraction. He gave a more complete explanation of the lunar libration than either Kepler or Hevelius, particularly in the determination of the quantities concerned; and though he did not leave the actual observations, Delambre, who, as we shall see, judges him severely, appears to think that he *did* establish by observation the coincidence of the nodes of the lunar equator and orbit. He was the first who carefully observed the zodiacal light, which he imagines he discovered. His later tables of the satellites of Jupiter (1692 and 1693) were considerable improvements; but though in possession of facts analogous to those which led to the discovery of the motion of light, he not only did not make that discovery, but rejected it when announced by Roemer. For his arc of the meridian, his observations relative to refraction, with a multitude of other points too long to notice here, we must refer to Delambre, *Hist. d'Astron. Mod.*, vol. ii.

We have seen that Cassini, as an observer, was no ordinary man. Even if we leave out of view discoveries such as those of the satellites of Saturn, which though brilliant involve no extraordinary sagacity, we have still the continued, systematic, and successful observations of the satellites of Jupiter. But as a philosopher, and as a reasoner upon the results of his observations, Cassini does not excel. An obstinate follower of Descartes, we have no evidence that he ever looked into Newton; probably his mathematical knowledge was not sufficient to enable him to understand the *Principia*. A devoted, if not a bigoted, adherent of the church of Rome, he was a Ptolemaist long after the time when Galileo had made the speculation of Copernicus sound astronomical doctrine; and we cannot give much admiration to the power of a mind which enslaves itself to a church in a matter of science. His unskilful handling of Kepler's laws, his erroneous and unsatisfactory notions upon comets, and indeed method of dealing with almost any subject which involved investigation, are so many points which render the extravagant praises of Fontenelle and Lalande altogether inadmissible. His reputation, in fact, was altogether of a different species from that which it ought to have been. So far as that sort of notoriety is concerned with which the public in general is most struck, Cassini and William Herschel appear to resemble each other. Nevertheless, take from the latter Uranus and six satellites, with two of Saturn, and there is left a first-rate reputation among astronomers; withdraw the similar discoveries of Cassini and he remains a commendable and even a remarkable observer, but by no means in his present rank. And it must be remarked that there is throughout Cassini's writings a continual tendency, either from ignorance or vanity, to appropriate the discoveries of predecessors or contemporaries. He speaks of himself as the first who observed the variation of the moon's diameter depending upon her altitude. 'Ours,' says Delambre, in one of his parentheses, 'le premier après Kepler, Auzout, et Hevelius.' The summing up of this searching historian is worth extracting. 'But why, we may ask, has Cassini so universal a reputation? Why has he had more praise to his own share than all astronomers together, at least during their lives? Firstly, because there was in him much to praise; because he was industrious, because he kept public attention constantly awake, because he employed for the most part unusual means, such as his gnomon and his long telescopes; and because, being invited to France as a man who could not be done without, the world early became accustomed to consider him superior to those who had wished him to join them. He was a conquest for which the monarch was praised, and all the fluges bestowed upon him went indirectly to the king. He attributed (faisait honnêtement) all his discoveries to Louis XIV.: he was the favourite astronomer of the court, so that it did not need as much as he had to secure him more reputation than any other. All the world understood Cassini's discoveries; Jupiter turned in 3h. 56m., Venus in 23h. 20m., Mars in 24h. 48m., Saturn had four moons, which no one had seen till then, and a medal had been struck to commemorate the latter. In reality, these phenomena were isolated novelties, infinitely curious things, which all astronomers are very glad to know, but which could have been omitted without any result in the smallest degree prejudicial to the progress of real astronomy. If we feel authorized to reproach any one it is not Cassini, but his contemporaries.' On the other

hand Lalande, an astronomer of real merit but of great want of judgment, has the following absurd exaggeration: 'Cassini was one of those rare men who seem formed by nature to give a new face to the sciences; astronomy, augmented and perfected in all its parts by the discoveries of Cassini, underwent in his hands a most astonishing revolution. This great man was the chief glory of the glory of Louis XIV. in this respect, and the name of Cassini is almost synonymous in France with that of the creator of astronomy.' On which we can only say—may every Lalande find a Delambre!

The writings of Dominic Cassini are numerous, and a complete list may be found in Lalande's 'Bibliographie Astronomique.' It is a presumption, so far as it goes, of the accuracy of the character given by Delambre, that none of these writings are now sought after as containing matter of any lasting value, except only the pure results of observation.

II. JAMES CASSINI, son of Dominic, was born at Paris, February 18, 1677, and at seventeen years of age was thought of sufficient promise to be received a member of the Academy of Sciences. He accompanied his father to Italy in 1695, and afterwards travelled in England and Holland where he became acquainted with Newton, Flamsteed, &c. He succeeded his father at the observatory, was maître des comptes, and died April 16, 1756. He was proceeding to his estate of Thury, when the carriage was upset. The blow became immediately paralytic.

There is not much of brilliancy in the results of the life of James Cassini as compared with those of his father, whom, on the whole, he much resembled in the character of his methods of observing and dealing. He was a better mathematician, and devoted himself for the most part to fundamental points of astronomy, and to the construction of tables. His separate writings are not numerous; some of these—optics by himself and his brother (afterwards killed as before stated) were published in 1691, being nothing but college exercises. The others are, 'De la Grandeur et de la Figure de la Terre,' Paris, 1720; and 'Eléments d'Astronomie,' Paris, 1740.

The first of these two works (a *suite* to the *Mém. Acad. Sci.* for 1719) contains the account of the continuation of Picard's arc of the meridian, begun by Dominic Cassini and La Hire in 1680, and recommenced by Dominic and James Cassini in 1700. On the results of this measurement Dominic Cassini concluded that the earth was a spheroid elongated at the poles, contrary both to theory and other observation. Much discussion was excited at the time [GEOGRAPHY]. The second work is an elementary treatise, which seems intended to explain his own and his father's astronomy. It is accompanied by a volume of tables, which must be considered as the joint work of the father and son. This collection was republished when the original edition became scarce, but with so many errors of press as to diminish its value materially. The correct edition is that of the Imprimerie Royale, Paris, with the fleur-de-lis in the title page. From this work we see that James Cassini seems biassed, which is no great matter of surprise, in favour of his father, even to the extent of declaring that the hypothesis of the successive propagation of light, which all the world knew to belong to Roemer, was in fact stated, examined, and rejected, by Dominic Cassini. He cites the *Mémoires* of the Academy of Sciences, which when examined by Delambre were found to contain nothing in support of the assertion, but showed very distinctly that Cassini and Roemer were in controversy upon the subject, and that nothing but the rejection of the hypothesis now known by the name of Roemer appears to have belonged to Dominic Cassini. It appears also that James Cassini was rather Copernican in his notions, but not very strongly determined; that he knew nothing, or next to nothing, of the system and writings of Newton (*Principia*, 1687, J. Cassini's *Astronomy*, 1740), which he cites in two places, once to endeavour to explain the acceleration of Jupiter's motion, in another for observations of a comet. He knows nothing of Bradley's discovery of aberration (1727-28), but Delambre has forgotten when he adds 'that he knew nothing of that of nutation, which was not published till 1747.' He appears to be, like his father, a follower of Descartes, and also, like him, to prefer graphical methods to calculation. His ideas upon the theory of comets would have been much the better for the study of Newton. Nevertheless, as an observer, J. Cassini was distinguished. His determinations of the times of revolution of the five satellites of Saturn then known are

very exact; he first observed the inclination of the orbit of the fifth (now the seventh) of them. He improved the methods and tables of refraction: determined very nearly the variation of the obliquity of the ecliptic, and the length of the year by comparison of a large number of equinoxes of his own and others. He left also a great number of good observations. Nevertheless, it is but justice to Picard and Rôcner to remember, that both of the Cassinis put together, distinguished as they were, did absolutely nothing which can now bring them to the daily remembrance of the astronomer, though their fame has surpassed that of the re-inventor of the micrometer, and the inventor of the transit instrument.

III. CÆSAR FRANCIS CASSINI, son of James, was born at Paris, June 17, 1714. He is generally known by the name of Cassini de Thury, having been the first to take a territorial appellation from the estate acquired by his father or grandfather. He accompanied his father during his geodesical operations in 1733, and was received member of the academy at the age of 21. He succeeded his father as director of the observatory, and as *maître des comptes*, and died September 4, 1784, of small pox. His most remarkable labour is the large triangulation of France, published in 1744, under the title of '*La Méridienne, &c., vérifiée, &c.*' Paris. He nearly completed the large map of France, of which his son presented 124 sheets to the National Assembly in 1789. He made a long succession of observations at the observatory: but these, though they would have done credit to Dominic Cassini, were too late of their kind. The time was past in which a descendant of the first two Cassinis could compete with the rest of the world by his hereditary means only. We must refer to Lalande's '*Bibliographie*' for a list of his writings, and to Delambre (*Hist. d'Astron.* xviii. Siècle) for detail upon his astronomical observations.

IV. JOHN DOMINIC CASSINI, son of Cassini de Thury, and most commonly known by his title of Count, was born at Paris, June 30, 1748, and is still living. He is the first of his family who decidedly adopted the system of Newton, though the same may perhaps be said of Cassini de Thury, from some isolated passages in his writings. He was elected member of the academy in 1770, in which year he published the account of a voyage made by order of the king, for trial of the chronometers of Le Roy. He was employed in 1787 with Méchain and Legendre, in the operations for the junction of the observatories of Paris and Greenwich by a chain of triangles. He made repeated endeavours to induce the government to re-establish the observatory upon a new footing and with large instruments. The National Convention, apparently with the desire to force him to resign, resolved, in 1793, that the observatory should be placed no longer under the control of one person, but of four, who should take annual duty in rotation. Of the four the Count Cassini was one, and the other three were his own pupils. To this he refused to submit, and resigned his charge September 6, 1793. He received an order to quit the observatory in 24 hours; and in the following year was imprisoned for seven months. From that time he abandoned astronomy entirely, refusing either to take part in the great survey, or to belong to the Bureau des Longitudes, or to the Institute, though he entered the latter body under the empire. He fixed himself on his own estate, and devoted himself to the duties of the *conseil* of his department. His son, the fifth of the name, began an astronomical career in 1798, aged 16, but soon relinquished this pursuit for that of botany. He was a judge of the *cour royale*, and died of the cholera at Paris during the late prevalence of that disorder.

We have thus the history of the occupation of an observatory by the members of one family for 122 years, and in spite of the deserved reputation of all the observers in question for talent and assiduity, it must be asserted that the hereditary system did not succeed. Delambre remarks with some bitterness, that during the whole of the reign of the Cassinis, not 'one little catalogue of stars' issued from the national observatory. Picard had proposed the erection of large instruments, and the observation of right ascensions and declinations. To this Dominic Cassini was opposed, and in the usual course of things, such an error would have lasted for his life, and would have been repaired by his successor. But when the first Cassini was followed by a second, and a third, wedded to the ideas of their common ancestor, there could be no improvement; and the consequence is that the observatory of Greenwich, for the same period,

bears away the palm from that of Paris, in actual use of astronomy. Had the National Convention adopted the sound ideas of Count Cassini the case might have been altered. The errors of his predecessors appeared to be fully known to him, and had he been allowed to rectify them, it is probable that the fifth Cassini would not have abandoned the career of his ancestors, and we might have seen the observatory of Paris, such as it has been since the accession of Napoleon, still in the hands of the distinguished family who had connected their name with all its previous history.

CASSIODORUS MAGNUS (or, as some call him, MARCUS) AURELIUS, who lived in the sixth century, was a man of letters, an historian, and a statesman. He composed a history of the Goths in twelve books, which is only extant in the abridgment of Jornandes; and he caused the ecclesiastical histories of Sozomen, Sozomen, and Theodoret to be translated into Latin by Epiphanius, under the title of '*Historia Tripartita*.' Twelve books of his letters are extant: the first ten consist of instructions relating to the senate, and written in the name of Theodoric, and his successors, Amalasontha, Athalaric, Theodatus, and Vitiges; the two last consist of similar papers written in his own name. They extend from the year 509 to 539. He also composed a treatise *De Artibus ac Disciplinis Liberalium Literarum*, upon grammar, rhetoric, logic, arithmetic, music, geometry, and astronomy; a treatise on orthography, an exposition of the psalms, and other religious works. He enjoyed a high reputation among his contemporaries for learning, eloquence, and talent; but his Latin is impure, and his style full of the conceits of the age.

He was born at Seylacium, in the country of the Bruttii, probably about the year 470, though some date his birth ten years later. His father, also named Cassiodorus, was high in office under Odoacer and Theodoric; and he himself was early introduced to public life under the former, and obtained the confidence of the latter, under whom he filled the offices of secretary and quaestor. By Theodoric's successors he was appointed master of the offices and prætorian prefect. Under the reign of Vitiges, about the age of 70, he retired from the world, and founded the monastery of Viviers, in Calabria, where he lived nearly to the age of 100 in devotional retirement, enlivened by the exercise of his mechanical ingenuity in the construction of water-clocks, dials, &c., the collection of a valuable library, and composition. His last work, '*De Orthographia*,' he states in the preface to have been written in his 93rd year. The best edition of his works is that of Garot, Rouen, 1679, in 3 vols. fol., reprinted at Venice; which contains the abridgment of Jornandes and the *Historia Tripartita*, with a life prefixed. There is also a life of Cassiodorus in French, by Sainte-Marthe. Paris, 1690. 12mo. As to the character of Cassiodorus, and the literature of his age, the reader may consult Schlosser, *Universal Historische Uebersicht*, &c. iii. 4.

CASSIOPEA (zoology). [MEDUSA.]

CASSIOPEIA. This constellation is called *Cassiopeia* (*κασσιόπειρα*) by Aratus, and Cassiopea by Manilius. In the Greek fable, Cassiopeia is the wife of Cepheus and mother of Andromeda, placed in the heavens with her head from the pole, so as to turn round apparently upside down, because (according to Hyginus) she boasted of her own beauty as superior to that of the Nereids. This constellation may be found by looking on the side of the pole opposite to the Great Bear, where will be seen five rather bright stars disposed in something like an M. These stars are also in a line drawn from Capella to the bright star in Cygnus, and about half way between them. The old figure is that of a woman sitting in a chair or throne, with a branch in her hand. The constellation is on the meridian at midnight, about the end of September, and at eight p.m. about the end of November. The remarkable star which appeared in this constellation in 1572 has been noticed in TYCHO BRAHE, who also affirms that similar stars appeared in 945 and 1264, whence Sir J. Herschel thinks it possible another such appearance may take place in 1872. But the authority for the first appearance is that of a contemporary of Tycho Brahe, from nameless manuscripts, and as comets are recorded in or about both 945 and 1264, these may have been the stars spoken of. See the '*Companion to the Maps of the Stars*,' of the Society for the Diffusion of Useful Knowledge. Baldwin, 1836, p. 86.

The following are the principal stars —

CASSIQUIARI. [AMAZON, p. 417; BRAZIL, p. 360.]

CASSIS. [ENTOMOSTOMATA.]

CASSITERIDES. (Κασσιτεριδες) a group of islands, generally supposed to be the Scilly Islands. They are first mentioned by Herodotus (ii. 115), who professes, however, his entire ignorance of them. Strabo (ii. 175) observes—'The Cassiterides are ten in number, and lie near to one another, to the north of the port of the Artabri (Cape Finis-terre), out in the open sea. One of them is uninhabited, but the rest are occupied by people who wear black clothing coming down to the feet and tied round the chest. They go about with sticks in their hands, and with beards as long as that of a goat. They live mainly on their flocks in nomadic fashion. They have mines of tin and lead, which with skins they give in exchange for earthenware, salt, and copper vessels, to the foreign merchants. In former times, the Phœnicians alone used to make this voyage from Gadeira (Cádiz), and kept it a secret from all the world.—The Romans, after repeated efforts, became acquainted with this navigation. P. Crassus having passed over to the islands, observed that the mines were worked at a very small depth, and that the inhabitants were peaceably disposed,' &c.

The Greek name of the metal 'tin,' which is cassiteros, (κασσιτερος) occurs in the Iliad of Homer, and the name of the islands is obviously derived from the name of the metal. Cassiteros however may not be a genuine Greek word. It is difficult to suppose that Strabo's description applies to any other place than the Scilly Islands, and yet their position is not very accurately given by him.

CASSIUS, CAIUS LONGINUS, appears in history for the first time as the quaestor of Crassus, in the unfortunate campaign against the Parthians, B.C. 53. He foresaw the consequences of the expedition into Mesopotamia, and warned his general against it, but without effect. He commanded a wing of the Roman army in the battle where they were defeated; and in the retreat from Carrhæ, discovering the treachery of the guides, he took his own course with 500 horse, whom he conducted alone out of that army safely back into Syria. Succeeding to the command of that province, he held out Antioch against the Parthians, inflicted a signal defeat upon their troops retreating from Antiochia, and drove them, for a time, across the Euphrates. Upon the arrival of the proconsul Bibulus, B.C. 51, Cassius returned to Rome, having acquired great credit by his conduct.

A break occurs in his history, until, after the battle of Pharsalia, B.C. 48, when we find him in Pompey's service, commanding a fleet in the Hellespont. There he had the opportunity of ending the war by taking Cæsar prisoner, who fell in his way accompanied by a very few ships; but instead of doing so, by some strange indiscretion or treachery, he obeyed Cæsar's summons to surrender, and passed over to his side. Again we hear no more of him until the conspiracy against the dictator's life, in which he was a principal, and he was chiefly instrumental in drawing M. J. Brutus, whose sister he had married, into the plot. He had

shared in Cæsar's favours, having been appointed by him to a prætorship, and to the command of Syria. Of the latter Antony endeavoured to deprive him, and procured a vote of the people to transfer it to Dolabella. Cassius, who had passed into Greece with Brutus, no sooner heard of this than he hastened into Asia, and speedily collected forces, with which he mastered Syria, Phœnicia, and Judæa; and he was on the point of invading Egypt, when letters from Brutus summoned him to return towards Europe, to make head against the triumviri. After conquering and plundering Rhodes (B.C. 42), he joined Brutus at Sardis, and the united army marching through Thrace into Macedonia, encountered Antony and Octavianus in the plain of Philippi. Cassius wished to avoid a battle as long as possible, being aware that the enemy must soon become straitened for provisions. But Brutus was eager to fight, and as the soldiery also began to murmur at what they called the cowardice of their generals, Cassius was obliged to yield. In the battle he commanded the left wing, and was opposed to Antony. Brutus in the right broke the troops of Octavianus, and drove them off the field; but pursuing his advantage too far, he exposed the flank of Cassius, who was then taken at disadvantage by his able antagonist, and compelled to quit the field. Thinking that all was lost, he put an end to his life. On hearing of his death, Brutus honoured him with the appellation of the 'last of the Romans.'

Cassius was esteemed one of the best generals of the age; his private character was good, though his temper was stern, and he professed a warm attachment to the republican cause. He has not escaped the imputation of being influenced by private enmity in his hostility to Cæsar; and the abrupt way in which he abandoned Pompey's cause is calculated to excite suspicions unfavourable to his character. In his philosophical opinions, he belonged to the Epicureans. See Cicero, *Ep. ad Div.* xv. 19.

CASSIVELLAUNUS. [BRITANNIA.]

CASSOWARY. [STRUTHIONIDÆ.]

CASTALIA (zoology). [SUMMITLACEÆ.]

CASTALION or CHASTEILLOIN, SEBASTIAN, was born in Dauphiné, some say in Savoy, about 1515. He applied early to the ancient languages, and became a great proficient in Greek and Hebrew. Being at Strasburg in 1540-1, he made the acquaintance of John Calvin, who invited him to Geneva, and had him appointed to a chair in the college of that city. After two or three years, Castalion having become obnoxious to Calvin on account of some of his opinions, which were not in accordance with Calvinistic orthodoxy, especially on the subject of predestination, left Geneva for Basel, where he employed himself in teaching Greek and in writing several works, chiefly on Scriptural subjects. He wrote 'Psalterium reliquaque sacrarum Litterarum Carmina et Precationes, 1547, with notes; 'Jonas Prophetæ, heronæo carmine Latino descriptus; 'Dialogorum Sacrorum ad linguam et mores puerorum formandos, libri iv.' This last work has been translated into English by Dr. Bellamy, under the title—'Youth's Scripture Remembrancer, or select sacred Stories, by way of familiar Dialogues, in Latin and English, with a short Application of each Story,' London, 1743. He also published a version in Latin verse of the Sibylline books, with notes, and a Latin translation of the Dialogues of Bernardino Ochino. Before he left Geneva, he had undertaken a complete Latin version of the Bible from the Hebrew and Greek, which he completed at Basel, where it was published in 1551, and dedicated to Edward VI. of England. He published a French version of the same in 1555. Castalion's versions were made the subject of much conflicting criticism. His Latin Bible went through several editions; that of Leipzig, 1697, contains also his 'Delineatio Reipublicæ Judaicæ ex Josepho; 'Defensio versionis Novi Fœderis contra Th. Beza; and 'Nota prolixior in cap. ix. Epistolæ ad Romanos.' He carried on an epistolary controversy with Calvin and Beza, who assailed him with many charges, and even urged, though ineffectually, the magistrates of Basel to drive him away. He passed his latter years at Basel in great poverty, and died in 1563, leaving a numerous family in want. He was buried in the cathedral, through the exertions of three Polish gentlemen who had been his pupils. In his latter years he was in the habit of resorting to the banks of the Rhine or of the Birs when swollen, where with a crook he endeavoured to catch the pieces of wood and branches of trees which the river carried along, in order to procure fuel for his family. This was made the subject of a charge by

Calvin, as if he had been guilty of pilfering. In 1562, Castellan published his eloquent 'Defensio suarum Translationum Bibliorum et maxime Novi Testamenti,' in which he speaks of himself and his works with the frank earnestness of an injured person. His 'Dialogi IV. de Predestinatione, Electione, Libero Arbitrio, ac Fide,' were published in 1578, by Faustus Socinus. He has been abused both by Calvinists and Roman Catholics; Arminian critics have been more indulgent to him. He wrote a treatise to prove that magistrates have no right to punish heretics. (Bayle's *Diet.*, edit. 1730, art. *Castellan*.)

CASTANEA, the botanical name of the plants which the English call sweet chestnuts. From the similarity in the name one would be disposed to believe that the genus to which horse-chestnuts belong was nearly related to this; they are, however, extremely different in every thing except the unimportant circumstances of the fruit of both being prickly; and even in regard to this, their resemblance is more apparent than real, for the prickly part of the fruit of *Castanea* is an involucre, while that of the horse-chestnut is a pericarp; and the so-called seeds of *Castanea* are seed-vessels, while the parts which in the horse chestnut correspond with these are really seeds. [*ÆSCULUS*.]

The sweet chestnut, or Spanish chestnut (*Castanea vesca*), is a deciduous tree of considerable size, with long shining serrated sharp-pointed leaves, clusters of long spikes of pale greenish-yellow unisexual minute flowers having no corolla, and fruits consisting of a roundish prickly husk or involucre, technically called a cupula, and analogous to the cap of the acorn or the beard of the albert, in which are contained one or more dark brown ovate sharp-pointed nuts, each of which conceals a large single seed, and is tipped by the remains of several rigid styles. The seeds contain a large quantity of nutritious starchy matter of a sweet flavour, on which account chestnuts are extensively used as food in the countries where the tree abounds. In all Spain, the southern parts of France, Italy, and the adjacent countries, sweet chestnuts, either raw, or roasted, or ground into flour, or prepared in some other way, form a common article of diet. It is however not the wild *Castanea* which furnishes the nuts that are principally consumed in the south of Europe, and exclusively exported to more northern countries, but a number of cultivated varieties, the nuts of which are larger, and the seeds sweeter; of these the most remarkable are the *Corice*, the *Ganicaude*, the *Igalade*, and the *Murron cornu* of the south of France. The sweet chestnut is a native of all the southern parts of Europe, extending eastward to the Caucasus, beyond which it hardly passes in Asia. In North America it occurs wild in great abundance in the hilly and mountainous parts of Virginia, the two Carolinas, and Georgia, as well as other districts, not however reaching beyond New Hampshire to the north. Michaux distinguishes the American from the European chestnut as a peculiar species, but hardly upon sufficient grounds. It is always included as a wild plant in our English Floras, but upon no sort of authority. It is said indeed that its timber forms a considerable part of our oldest buildings, and that it has been ascertained to be the material out of which were constructed the ancient piles that have from time to time been taken from the Thames, the roof of Westminster Abbey, the church of St. Nicholas at Great Yarmouth, erected in the reign of William Rufus, and the timbers of other places; but these statements have arisen from the singular mistake of confounding the timber of *Quercus sessiliflora* with that of *Castanea vesca*; it is to the former that are to be referred all the supposed cases of ancient chestnut wood found in English buildings. [*QUERCUS*.] The sweet chestnut in its wild state acquires an unusual size; on Ætna, where it constitutes forests, there are trees of great antiquity, one of which is called 'the hundred horse chestnut,' from its being able to contain a hundred mounted men in its hollow, has or had a circumference of above 160 feet; and in the department of the Cher, near Sancerre, there is still standing a tree of this species, which at six feet from the ground measures more than thirty feet in circumference, and is to all appearance still sound. It is stated that 600 years ago this was called the great chestnut tree, and its actual age is computed at 1000 years. The wood of the chestnut is well suited for piling or piles, as it resists well the influence of water; it is also used for mill-timber and for water-works, but it is not in this country of much importance; it is said to produce one of the best kinds of charcoal.

Several varieties are cultivated in this country, among which are a shining-leaved, a variegated, and a cut-leaved

sort; they are multiplied by grafting on the common sweet chestnut.

Castanea pumila, or the Chinquapin nut, is a shrub rather than a tree, with leaves hairy on the underside, and small sweet nuts; it is a native of the United States of North America, especially in damp mountainous situations on a gravelly soil.

There are some other species in India and on the west coast of North America; but being unknown in this country they need not be described in this place.

CASTANETS, a musical instrument of percussion, of Moorish origin, composed of two small concave pieces of chestnut wood (hence the name) or of ivory, in the form of cockle shells, united at one end by a string, hung on the forefinger and thumb, and struck together in musical time, while the performer is dancing.

CASTANOSPERMUM, a remarkable genus of *leguminous* plants, the only known species of which is described as forming a tree thirty to forty feet high, in the forests near Moreton Bay in New Holland. It has unequally pinnated leaves, with elliptical ovate acuminate entire smooth leaflets. The flowers are papilionaceous and bright saffron-yellow. The pods are large, solitary, and pendulous, produced by the two years old wood, obtuse, rather inflated, and containing from three to five large chestnut-like seeds. The shade afforded by the foliage is said to excel that of most Australian trees. By the natives the seeds are eaten on all occasions; they have when roasted the flavour of a Spanish chestnut, and travellers assert that Europeans who have subsisted upon them have experienced no other unpleasant effect than a slight pain in the bowels, and that only when the seeds are eaten raw. They are however hard, astringent, and not at all better than acorns. (Hooker's *Botanical Miscellany*, vol. i. p. 241; vol. ii. p. 51, 52.) The plants have been introduced to this country by the Horticultural Society, but they will not live out of doors in the winter.

CASTEL, the name of several places in France, most of which are distinguished by some distinctive addition to the name, as Castel Sarasin, &c.

CASTELLI, BENEDICT, was born at Brescia in 1577, and died at Rome in 1644. He was a Benedictine, and taught mathematics at Pisa, and afterwards at Rome. He is known as having been a defender of the hydrostatical doctrines of Galileo, in his 'Risposta alle opposizioni,' &c., Florence, 1615. He also was the first who applied the new doctrines of motion to hydraulics, on which subject he is to be considered as the earliest writer of the experimental school. In his treatise 'Della Misura dell' Acque Correnti,' Rome, 1638, he explains several phenomena, but was misled by a notion that the velocity of issuing water is proportional to the height of the reservoir, instead of the square root of the height. Bernard Castelli, a painter, was born in the same year at Genoa. (Montucla, ii. 201; iii. 579, *Biog. Univ.*) There are some works of his in 'De Motu Aquarum Currentium,' Florence, 1723, and a life published at Dresden in 1746.

CASTELLO, CASTEL, an appellation, which is a component part of the names of many Italian, Portuguese, and Spanish towns. It is derived from the Latin *Castellum*, a diminutive of *Castrum*, which meant originally a fort or castle, and this is to this day the meaning of the Italian appellation *Castello*; but afterwards it was applied to the villages or assemblages of houses which gradually arose round the fort. Many of these villages have become considerable towns, and are surrounded by walls; and though the original castle has disappeared, they still retain the old name of *Castello* or *Castel*, joined to some local denomination which particularizes each of them, such as *Castel Goffredo*, *Castelforte*, *Castelnovo*, *Castellamonte*, &c. The number of towns and villages whose names begin with *Castel* is very considerable in Italy. The principal are: *Castellamare*, i. e. 'Castle by the sea,' a pleasant well built town on the Bay of Naples, opposite the capital, and near the site of the ancient *Stabie*, with various mineral springs, a royal villa, and docks for the navy; population 15,500. There is another *Castellamare* in Sicily, on the gulf of that name, a small town on the site of the ancient port of *Segeris*, 25 miles S.W. of Palermo. *Castel Vetrano* is a town of 12,000 inhabitants, in the province of Trapani, 6 miles N. of the ruins of the ancient *Selinus*. *Castel Gandolfo*, in the papal state, is a pleasant village on the banks of the Alban lake, with the country residence of the pope, and near it the remains of the villa of *Domitian*. [*ALBA LONGA*.]

In Tuscany is Castel Fiorentino, a thriving town of 3000 inhabitants, in the Val d'Elsa, 16 miles S.W. of Florence. In the Duchy of Parma are Castel San Giovanni and Castel Guelfo. In the Sardegnian states are Castelnovo di Serria, near Tortona, with 5000 inhabitants; Castellamonte, in the province of Iwrea, 4000; Castellazzo, in the province of Alessandria, 5000. In the island of Sardinia is Castel Sardo, a seaport, N. of Sassari. There are also several towns in Italy called Castiglione or Castellone, which is an augmentation of Castello, such as Castiglione Fiorentino, a town of 5500 inhabitants in the Val di Chiana, in the province of Arezzo, and Castiglione, in Lombardy, in the province of Mantua, near which a great battle was fought between the French and the Austrians, in August, 1796. [BONAPARTE and AUGEREAU.] There are also in Tuscany several places called Castiglione, i. e. 'little castle.'

In Spain, names of towns beginning with Castell are chiefly found in the eastern provinces, where the Limousin and Catalanian, which are dialects of the Romance language, are spoken. There are several in Catalonia, such as Castellfollit, Castello di Ampurias, &c. In Valencia is Castello della Plana, 50 miles N. of Valencia, near the sea. In Portugal are several others, the principal of which is Castello Branco, or 'white castle,' a considerable town built on a hill in the middle of a large and fertile plain in the S. part of the province of Beira. It is a bishop's see and the head town of the Comarca or administrative province of the same name, which includes 97 parishes. [BEIRA.] There are also Castel Rodrigo, a fortress in the N. part of Beira, not far from Almeida; Castel de Vide, in the Alentejo, near the frontiers of Spain, &c.

CASTELNAU, the name of several towns and villages in France, of which the most considerable will be noticed under their respective departments. This name is peculiar to the south of France.

CASTELNAUDARY, a town in France, the chief place of an arrondissement in the department of Aude. It is on the bank of the little river Biesquel, a feeder of the Aude and the great canal of Languedoc passes through it: it is 472 miles from Paris by the road through Orleans, Lunoges and Toulouse.

There seems to have been a town on the site of Castelnau in the Roman times, Nostomagus, mentioned in the 'Itinerarium à Burdigala Hierusalem usque.' This town is said to have been destroyed when the Visigoths settled in this part of France; the same people are stated some time after to have rebuilt it and fortified it. From them, as being Arians, Maure Brun derives its name, Castrum Novum Arianorum, whence, by corruption, Castelnau dary. Expilly, who writes the name with two r's, Castelnau dary, gives for its etymology Castrum Novum Arri. At a subsequent period it became the capital of the Lauraguais or Lauragais, a district so called from its original capital, Laurac, now an insignificant town. In the wars carried on against the Albigenses, Castelnau dary suffered severely, and again in the wars between the English and French. But the event which has made the place best known in history was the victory gained A.D. 1632 by Maréchal Schomberg, at the head of the troops of Louis XIII., over the malcontents headed by the duke of Montmorenci. The battle itself was little more than a skirmish brought on by the rashness and signalized by the valor of the duke, but it was rendered decisive by his being wounded and taken prisoner. He was afterwards executed for treason at Toulouse. The field of battle, on the banks of the Fiesquel, just below the city, and the house to which the wounded duke was taken, are still regarded as objects of interest.

The town stands on an eminence, and contains some well-built houses, but most of them have the roof projecting far beyond the body of the house, which defaces the outward appearance, and renders the interior dark and sombre. From the *hôtel de ville* (town-hall) there is a beautiful prospect. The church is well built, and contains a painting which is highly esteemed, by Rivals, an artist born near Toulouse; the subject is the Scourging of Christ.

The population of Castelnau dary in 1832 was 8471 for the town, or 2882 for the whole commune. The inhabitants are engaged in the spinning of wool, the machinery for which purpose is moved by water. The trade of the town is promoted by a fine canal, armed by the canal of Languedoc. The borders are shaded with trees, furnish an agreeable prospect, and the chief trade is in corn: wool, which was formerly

all, attended to. The town contains a high school and an agricultural society, and several charitable institutions. Among the natives of Castelnau dary may be mentioned Germain Le Felle, the historian of Toulouse, and General Androussy.

The arrondissement of Castelnau dary had, in 1832, a population of 52,659.

CASTES. [HINDUS.]

CASTI, GIOVAN BATISTA, was born in 1721 in the Roman State. He studied in the seminary of Montefiascone, and afterwards took priest's orders. Little is known of his early life, until 1762, when he published 'I Tré Giuli,' a series of 200 sonnets on the subject of a debt, amounting to three giuli or paoli, a Roman coin worth about five pence, which the author describes himself as having incurred. His merciless creditor insisted upon immediate payment, which the poet endeavours to put off by all sorts of ingenious devices, by flattery, entreaties, threats, &c. A rich vein of humour and facetiousness runs throughout the whole composition. The 'Tré Giuli' have been translated into English, London, 1826. In 1763, Casti went to Florence, where by his wit, as well as by his real information, he found favour with the Grand Duke Leopold and his court. When Joseph II. visited Florence in 1769, he became acquainted with Casti, and invited him to Vienna, where the poet was well received; and he afterwards attended Prince Kaunitz, the prime minister, in several diplomatic missions. In 1778 he went to Russia, where he was introduced to Catherine II., and where he conceived the plan of his 'Poema Tartaro,' which contains a satire on that empress and her court under fictitious names. He afterwards returned to Vienna, where he obtained the situation of Poeta Cesareo, or court poet, vacant by the death of Metastasio in 1782. He there composed some burlesque dramas, among others 'Il Re Teodoro a Venezia,' which was set to music by the great composer Paisiello; and 'La Grotta di Trofonio,' which is a sort of satire upon philosophers. He wrote another opera buffa, in which he parodied the story of Catiline's conspiracy, and Cicero's part in that transaction. It is said to be extremely humorous, but we do not find it among his printed works. About the time that the French entered Italy in 1796, Casti left Vienna for Milan, where he showed himself a warm partisan of republicanism. He lived afterwards some time at Florence; and lastly, in 1798, he visited Paris, where he remained till his death in February, 1803. At Paris he published in 1802 his 'Animali Parlanti,' a poem, which is his chief title to fame. It has been called a satire on courts, but it might be styled as well a satire on political society in general, for the author lashes demagogues as well as courtiers. It has been partly translated and partly imitated by W. Stewart Rose in his 'Court and Parliament of Beasts,' London, 1819. Casti had much of the humour peculiar to Berni's school [BERNI], of which he may be considered as one of the last specimens, although he rose higher in the choice of his subjects, and in the freedom of his allusions. A complete edition of his 'Novelle Galanti' was published in 3 vols., 8vo., Paris, 1804. They are humorous stories in verse, and the subjects are much after the fashion of Boccaccio's tales, written in a fluent style, but mostly licentious. Casti by this work placed himself among the very few independent Italian writers of the eighteenth century.

CASTIGLIONE BALDASSARRE, was born of a noble family in the State of Mantua in 1478. He studied at Milan under Merula and Demetrius Calchondylas, and afterwards returning to Mantua he entered the service of the Duke Francesco Gonzaga, whom he accompanied in his campaign in South Italy, when Gonzaga led the French army to the conquest of Naples. After the defeat of the French by Gonzalo of Cordova in 1503, Castiglione repaired to Rome, where he attached himself to the court of Guidobaldo di Montefeltro, Duke of Urbino, who was a patron of literature. During his residence at Urbino, he enjoyed the company of Bembo, Bibuena, Giuliano de' Medici, and other distinguished men who graced that little court. In 1506 he was sent by the duke to England on a mission to Henry VIII., who was pleased with him and made him a knight. After Duke Guidobaldo's death, he followed his successor Giuseppe Maria della Rovere in the campaign against the Venetians. When Leo X. ascended the Papal throne in 1513, Castiglione was sent as ambassador to him. Some years afterwards he was recalled to Mantua by his natural sovereign the Duke, and employed by him on several missions, and

after some years was sent again to Rome to Pope Clement VII., who took him into his own service and appointed him his ambassador to Charles V. While Castiglione was residing at Madrid in this capacity, the news came of the taking and sacking of Rome by the Imperial army in 1527. This unexpected catastrophe affected the mind and the health of Castiglione, who became disgusted with courts and politics. Charles V., who valued him, offered him the bishoprick of Avila, which he refused. After lingering in Spain another year, he died at Toledo, in February, 1529.

The principal work of Castiglione is his treatise in the form of a dialogue 'Del Cortigiano,'—Of the Courtier. He wrote it while he was at the court of Urbino, which happened to be then a very favourable specimen of courts. Castiglione specifies all the qualities which an accomplished and intelligent and at the same time honest courtier ought to possess, and the manner in which he ought to use them for the good of his prince. The 'Cortigiano' has been much and long admired in Italy, both for the thoughts and the style, and it still ranks among the classical works of the sixteenth century. Castiglione wrote also poetry, both Latin and Italian: his 'Lettere,' or correspondence, were published by Serassi, in 1769, 2 vols., 4to., with a Biography of the Author.

CASTILLA, is the name of one of the two kingdoms by the union of which the present Spanish monarchy was formed; and it is also the name of one of the great territorial divisions of present Spain. The name appears to be derived from 'Castellum,' a castle, in Spanish 'Castillo'; and the arms of Castile exhibit several towers or castles in their shield. The kingdom of Castile was originally one of the several Christian kingdoms formed in Spain as the Christian population which had taken refuge in Asturias, advanced gradually S. of their mountains, and gained ground in the interior over the Moors. Castile had first its counts, who were dependent on the kingdom of Leon; but in the eleventh century it became a separate kingdom, which by degrees extended over the greater part of Spain, embracing, besides the provinces which are still called Castile, the original kingdom of Leon and Asturias, Galicia, Extremadura, and lastly, Andalusia, after the final expulsion of the Moors. The kingdom of ARAGON embraced the rest or E. part of Spain. The two crowns became united by the marriage of Isabella, Queen of Castile, with Ferdinand, King of Aragon, A.D. 1471. After Ferdinand's death, 1516, Charles I. (V. of Germany) inherited both crowns, which have remained united ever since, although in the official and administrative language they have continued to be styled as separate crowns, each having its respective laws, usages, and prerogatives. For the ancient constitution of Castile, see CHARLES V. Of late years the administration, both political and judicial, has assumed a more uniform system over all Spain, the whole country being divided into intendencies or provinces, without regard to the boundaries of Castile and Aragon.

By the territorial division of Spain, which was in force from the time of Charles V. till the beginning of the present century, two of the largest provinces of the kingdom were called by the names of Old Castile, or Castilla la Vieja, and New Castile, Castilla la Nueva. They included together the most central part of Spain. We shall describe both under this head, specifying the provinces or intendencies into which they are now subdivided for the purposes of administration.

Castilla la Vieja is bounded N. by the Bay of Biscay, E. by the Basque provinces, Navarre, and Aragon, S. and S.E. by Castilla la Nueva, and W. by Leon. It extends about 260 miles N.E. and S.W. from Santander to the neighbourhood of Talavera la Reyna. Its breadth is very irregular; at its widest part, about the latitude of Burgos, it is about 110 miles; in other parts it varies from 60 to 70, and in some it is hardly 20. The principal river of Castilla la Vieja is the Duero, which rises in the mountains called Moncayo, 5000 feet high, one of the most elevated parts of central Spain. A ridge, under the names of Monte de Oca, Moncayo, &c., runs N.W. and S.E. through the provinces of Burgos and Soria, and parallel to the course of the upper Ebro, dividing the waters which run into that river from those which flow westwards into the Duero. From the Moncayo an offset descends itself in a S.W. direction, running by Medina Celi, Cuenca, Paredes, Ayllon, Baytrago, Somosierra, San Ildefonso, and the Escorial, where it assumes the name of Sierra

de Guadarrama. It then continues to the Sierra de Guadalupe on the borders of Estremadura. This long mountain ridge divides the waters of the Duero from those of the Tagus, and forms at the same time in several places the boundary between Castilla la Vieja and New Castile. The greater part of Castilla la Vieja lies N. of this ridge, and between it and the Asturian mountains to the N., forming a wide basin, watered by the Duero and the Pisuerga, and other affluents of the Duero, and sloping to the W., where it opens into the plains of Leon. North of the mountains of Reynos, which form part of the Asturian chain, lies the province of Santander, which is detached from the rest of Old Castile, although included in it as forming one of its administrative subdivisions. The district of Rioja, belonging also to Old Castile, lies E. of the Sierra de Oca, and is, geographically speaking, a part of the basin of the Ebro. Old Castile has many elevated plains, such as that of Avila, which is above 3400 feet high [AVILA]; and the high grounds E. of Burgos, and in the district of Soria, at the foot of the mountains of Oca and Moncayo, where the climate is cold, and the soil not very productive. The valleys enjoy a milder climate, and produce corn and wine. The country abounds in cattle and sheep; the latter are partly migratory, or merinos, and partly stationary. There are manufactories of woollens at Burgos and Segovia, of cottons and linsens at Avila and Soria, and glass manufactories at San Ildefonso.

Old Castile is divided into five intendencies or provinces: Avila, Segovia, Soria, Burgos, and Santander. The principal towns are—Burgos, an archbishop's see, with a number of churches and convents, and 12,000 inhabitants; Segovia, the ancient Segobia, which has a fine Roman aqueduct in good preservation, the alcázar or residence of the former Moorish kings, a fine cathedral, a military college, several manufactories of fine woollens, and 13,000 inhabitants; AVILA, 5000; Santander, one of the principal ports of N. Spain, with considerable trade, and 19,000 inhabitants; San Ildefonso, already mentioned, with its glass-works, a royal palace and gardens, and 4000 inhabitants. L'Escarial is another splendid royal residence, which is described under its proper head. The whole of Old Castile contains a population of 1,053,000, according to Mifano, exclusive of the clergy, military, students, vagrants, beggars, &c., whose numbers are not ascertained.

Old Castile and Leon are considered as the cradle of the Spanish monarchy. The people of Old Castile retain much of the old Castilian character for steadiness, sobriety, perseverance, and trustworthiness, united with a considerable degree of reserve, haughtiness, and taciturnity.

Castilla la Nueva is bounded to the N. by Castilla la Vieja, to the E. by Aragon and Valencia, to the S. by Murcia and Andalusia, and to the W. by Extremadura. It is 60 miles from N. to S., and 210 from E. to W. The two principal rivers are the Tajo and the Guadiana, both of which run westwards. The Tajo has its source in the W. side of the Sierra de Molina, a continuation of the Moncayo above mentioned, and which runs southwards along the border between Castile and Aragon, and then across the province of Cuenca, which is one of the most elevated in Spain, dividing the waters of the Guadalquivir and other rivers that flow through Valencia into the Mediterranean, from those which flow westwards into the Tajo and Guadiana. Offsets of this ridge enter Valencia and run in a S.E. direction to the coast of the Mediterranean. Between the southernmost end of this ridge, which Spanish geographers call Iberian, near Chinchilla on the borders of Murcia, and the Sierra de Alcaraz, which is the E. beginning of the Sierra Morena or Marianic range, is a plain in which stands the town of Albacete, and which separates the two ranges which many have supposed to be united. (Minaño, *Diccionario Geográfico*, art. 'España.') Through this gap the Xucar, which has its sources in the province of Cuenca in New Castile, passes on its way to the Mediterranean. On the N.W. slope of the Sierra de Alcaraz are the sources of various streams, which by their union form the Guadiana. The Guadiana crosses the province of La Mancha from E. to W., and then turning to the southward enters Extremadura. The waters that fall into the Guadiana from the N. are divided from those which flow into the Tagus by the ridge called Montañas de Toledo, which rise S.W. of the great central plain of Castile, in which Madrid is situated. The Montañas de Toledo join to the W. the Sierra de Guada-

lands, which run into Estremadura. The mountains of the interior of Spain form large irregular groups, separated by extensive elevated plains; and it is not so much the mountains as the general inclination of the plains, which determines the course of the rivers. Thus the Guadarmena and several other rivers which rise in Cuenca and La Mancha N. of the Sierra Morana, flow into the Guadalquivir, which runs S. of the same Sierra, and their sources are separated by the high lands of La Mancha, from the waters which run N.W. into the Guadiana.

The large mesas or plains of New Castile are chiefly sown with corn, and being entirely destitute of trees, for which the Castilians have a singular aversion, and very deficient in running water, they look desolate and burnt up, especially in summer. There are few villages in the plains. The hills, especially in La Mancha, are planted with vines, and produce some very good wine, such as the wine of Val de Peñas, which is mostly used at Madrid. Large flocks of sheep are reared in New Castile. In the province of Cuenca are iron mines and iron works. In La Mancha are rich mines of quicksilver [ALMADEN]. There are manufactories of arms at Toledo; of soap, paper, and linens, in Cuenca; of woollens at Guadalaxara; of silks at Talavera, besides the manufactories established in the capital [MADRID].

New Castile is divided into five intendencies: Madrid, Toledo, Guadalaxara, Cuenca, and La Mancha. The principal towns are Madrid, TOLEDO, ALANJUEZ, ALCALA DE HERNANDEZ; Guadalaxara, the chief town of the intendency of the same name, which has some good buildings, an ancient Roman bridge, woollen manufactories, and 7000 inhabitants; Cuenca, which is a bishop's see, has 9000 inhabitants; Ciudad Real, the chief town of La Mancha, with 8000 inhabitants, is known for its fairs and its excellent mules. The whole population of New Castile, including Madrid, is 1,602,000, according to Miñano, with the same exception as before, concerning the clergy, &c.

The principal high roads 'camino reales' of Spain branching out from Madrid cross Castile in different directions. That from Madrid to Burgos by Aranda de Duero, crosses the Somosierra ridge on the borders between Old and New Castile. From Burgos the road continues by Vittoria and Irun to France. This line of road is kept in good repair. Another very good road leads from Burgos to Santander, which is the shipping port for the surplus corn of Old Castile and Leon. The high road from Madrid to Estremadura and Lisbon leads by Talavera to Badajoz. The great southern road leads by Ocaña and through La Mancha, and by the pass of Despeñaperros into Andalusia. The great eastern road from Madrid to Valencia passes also through La Mancha to Albacete and Almazora in Murcia. The other or more direct road to Valencia through the mountains of Cuenca is in bad repair. Two roads lead from Madrid to Zaragoza, one by Sigüenza and Medina Celi, and the other by Molina and Daroca.

The canal of Castile was undertaken to facilitate the communication of the great corn plain of the Duero, both in Leon and Castilla la Vieja, with Reynosa at the foot of the Asturian mountains, from whence the corn is carried on mules or carts to Santander. It passes by Valladolid, Palencia, and Aguilar del Campos, and a branch of it extends to Burgos. The undertaking, however, is not yet complete. Want of communications is one of the principal drawbacks upon the industry and productiveness of the two Castiles. (Miñano, *Diccionario Geografico estadístico de España*; Laborde, *Itinéraire descriptif de l'Espagne*.)

CASTILLON, a small town in France, in the department of Gironde. It is on the right or north bank of the Dordogne, and on the road between Bergerac and Bordeaux. It derives its only claim to notice from its historical interest. When Guienne, long in the possession of the English monarchs, was conquered by the French, a number of the nobility of the province formed a plot for revailing

English, and Talbot, the most famous of the English captains of his day, was sent with a force of 4000 men to stain the revolted lords. Bordeaux opened its gates to him: he made himself master of Castillon and Fronsac, recovered all Guienne. The approach of the French was changed the face of affairs. Castillon was invested there, and Talbot, strengthened by some reinforcements in England, left Bordeaux, where he then was, to march to his relief. He attacked the French camp, which was

strongly fortified, but all the efforts of the hero, who was then upwards of 50 years of age, were unavailing. His army was defeated, himself and his son fell in the action, Castillon surrendered, and Guienne was re-united to the domains of the French crown. The battle of Castillon was fought A.D. 1453. The population of this town, in 1832, was 2528; that of the whole commune, 2897. There are several other places of the same name in France.

CASTING. [FOUNDING.]

CASTLE, from the Latin *castellum*, a diminutive of *castrum*, an encampment, is a walled inclosure with a tower or towers, strongly constructed and intended as a place of safety. Numerous castles, for the most part in ruins, still remain in various parts of Great Britain, France, Germany, Italy, and in the East; but our remarks are principally confined to those of this country. The castles of England consist of those erected by the Romans; of British and Saxon castles erected previous to, and Norman castles erected after, the Norman conquest; and also of the more modern stone and brick castles, erected from about the reign of Edward I. to the time of Henry VII. The Roman castles in this country are numerous, and some of them still in very perfect condition, such as Burgh Castle and Richborough. The Saxons most probably adapted the Roman inclosures to their modes of defence, and it appears that they often raised a mound on one side of the walls on which they erected a keep or citadel.

In various parts of England, Scotland, Ireland, and Wales, there are numerous encampments or castles, mostly occupying the summits of hills, which have been ascribed to the aboriginal inhabitants. Among the most remarkable are the Herefordshire Beacon, on the Malvern Hills, in Worcestershire; the Caer-Cardock, near Church Stretton, in Shropshire; Moel Arthur, in Flintshire; Chun Castle, in Cornwall; and Maiden Castle, in Dorsetshire. (Britton's *Arch. Dict.*)

Roman Castra were probably sometimes formed on the sites of British works. Richborough Castle, in Kent, perhaps the earliest Roman castle constructed in this island, has been conjectured to have been formed in the reign of Claudius, and completed by Severus. (Batteley's *Antiq. Rutupinae*, pp. 6, 14, &c.) It still retains the leading features of one of the most perfect of the stationary castles built by the Romans in England. The basement of the Sacellum, or small temple for depositing the ensigns, forms an important feature in this castle; and in the walls are the traces of the four gates. The entrance through the

[Plan of Richborough Castle, Kent.]

north-east wall is by one of the two gates (c) called by the Romans the Porta Principalis, and which became in after-times the postern gate. (King's *Munimenta Antiqua*, vol. ii., p. 16.) The Praetorian gate is supposed to have been on the side of the slope towards the estuary, which formerly bounded this side of the castle. The second principal gate was opposite the first principal gate or postern; and the Decuman gate and the Praetorian are presumed to have been nearly opposite. The form of this castle, like Burgh, is nearly a rectangular parallelogram, with rows of towers placed at intervals in the walls in a horizontal posi-

tion. These layers of bricks formed a fresh foundation for every succeeding layer.

Porchester Castle, another Roman station (Stow's *Annals*, p. 12) of a rectangular form, with hollow circular towers (a) at the angles and sides, presents examples of both Saxon and Norman adaptations and castle-building within its walls. The Roman gates (b, c) most probably the Decuman and Prætorian, have been fitted up with gates constructed after the Norman style of fortifying castellated entrances. The area of Porchester is 620 feet by 610. At the north-west angle a square Saxon keep (e), 57 feet by 58, has

usurped the place of one of the circular Roman towers. To this tower Mr. King supposes an addition to have been made by the Normans, who at the same time fortified it after their manner, forming an inner baillie or ballium within the outer baillie formed by the larger Roman inclosure. This keep may be considered the citadel of the castle, and was the residence of the chief officer. The keep of a Norman castle was to these people what the prætorium was to the Romans; and where the sacellum of the Romans was most probably situated a Christian church was often erected. At Porchester, where a Norman church still remains close to the Prætorian gate in high preservation. At Caistor, in Norfolk, the church is on the site of what was probably the ancient temple. The keep at Porchester is like most of the early Saxon keeps, adjoining to and upon the very outward wall of the castle area itself, unlike the Norman keep towers, which were usually in the clear open space of the castle area, as at Heddingham, in Essex, or unattached to the walls as at Rochester. The *Themelii* (*Opiliones*, layers of brick) are seen in parts of the Roman walls, which, like all the walls of Roman castra, are of rubble; while the Saxon and Norman works are usually faced with squared stones. The Norman gates were secured with a portcullis, a practice which it appears the Saxons did not adopt; there is no sign of a portcullis having been used in the Saxon keep at Porchester. At Nicopolis, near Alexandria, in Egypt, there is a Roman castle very similar in plan to the castle at Porchester previous to the Saxon and Norman alterations. (King's *Munimenta Antiqua*, pl. xxviii. vol. ii.) Pevensey Castle in Sussex is considered to have been a late Roman work, if not an Anglo-Roman building. The *Themelii* are not laid horizontally as at Richborough and Burgh, but more like the Saxon herring-bone. Like Porchester, it has had many subsequent additions in later times. The earlier works are far more durable than the later constructions. The plan is an irregular curve with solid towers, and a raised inner baillium with hollow towers, and a keep. The plan given in King's *Munimenta* is however very incorrect, giving nearly the form of a circle, while the real shape

approaches to that of a triangle with the ends round. The walls at Pevensey average ten feet in thickness, and twenty feet in height.

King, in his *Munimenta Antiqua*, gives some plans and views of castles which he thinks may have been constructed after the plan of Syrian castles, to which he argues they bear, in many parts of their plan, a strong resemblance. Launceston, Brunless, and others are mentioned by King as being of Phœnician origin, a position which it is much easier to assert than to prove. Conisborough, another singular castle, is considered by the same author to be an early British work.

Saxon castle-building was probably borrowed from the Romanized Britons, who had acquired a taste and knowledge of the arts from the Romans. Thus in Pevensey there are walls that have an appearance of Roman character and design, and yet are so much ruder in execution than any other Roman works, that they can only be referred to a time when the knowledge of the Roman arts, though yet fresh in the memory of the inhabitants, might probably be on the decline.

British, Saxon, and Norman castles have one principal feature, the keep-tower, which is a strong and massive building, placed either near the side of one of the external walls, or attached to them. As a general rule, Saxon castles have the keep-tower attached to the walls, and the Norman unattached; but there are exceptions in both cases, though we believe not many.

Among many others, King considers Castleton, in Derbyshire, to be a genuine Saxon castle, from the style of its architecture and the appearance of herring-bone masonry in the walls.

The keep (a) is attached to the walls of the castle, which is also fortified with one small square tower and another half tower. The castle-keeps at Guilford and Colchester castles have some curious herring bone construction in brick, which is considered to be a distinguishing mark of Saxon building. Goodrich castle-keep, which is also Saxon, is placed in a manner somewhat similar to those at Porchester and Pevensey; but the castle itself is Norman, and has four circular towers at the angles.

Norman castles, as fortifications, are the strongest. They consisted of mounds and ditches, or moats, with walls on the mounds surmounted with battlements; the walls were also fortified at the top with small projecting towers called bastions. In the walls were entrance gate towers, with bridges either of stone or wood, which were made to draw up and down. The entrances were also guarded with thick doors and portcullises or gates, which dropped down through grooves at the side of the masonry. All apertures, except the gateway, were usually very small. Platforms were made behind the parapets. The gateway was sometimes defended by a barbican, and also flanked by towers, as well as the outer walls. The keep was usually in or near the centre of the castle, and it had sometimes a chapel within it. Rochester castle, which stands on a small eminence near the bridge over the Medway, is a fine example of a Norman castle. It was probably rebuilt by the Normans, soon after the conquest, on the site of a more ancient castle,

[Rochester Castle, and Keep]

and presents a fine example of a Norman keep, 'which originally consisted of four floors, including the basement or dungeon story. It is about 70 feet square at the base, with walls varying from 13 to 8 feet in thickness, and rising to the height of 105 feet to the top of one of the angular turrets. The walls of the ground floor slope or bend inwards; but from that to the top they are continued perpendicularly. Externally there is a pilaster buttress near the centre of each side, and at three angles are square staircase turrets, and a rounded turret at the fourth angle. At the north face is a projecting work, forming a sort of vestibule to the chief entrance door-way to the first floor, and this is approached by a flight of steps commencing at the western side, and returning round the corner. The walls, doors, and windows are constructed to repel assailants.

The first ascent was by a flight of 12 or 13 steps, leading round the north-west angle to an arched door-way, beneath which a flight of seven steps led forward to a draw-bridge that connected with the arched gateway to the entrance-tower: this opened into the vestibule, between which and the keep there were no other avenues of communication than by a third arched passage in the thickness of the wall. This latter inlet to the body of the keep was defended by a massive door and portcullis, the hinges and grooves of which remain; and in the roof are openings for the purpose of showering missiles on the heads of assailants.

The interior of the keep is divided longitudinally by a strong wall into nearly equal parts, which communicate by open arches on each floor. In the centre of this wall is a well of considerable depth, 2 feet 9 inches in diameter, neatly wrought, open to the very top of the keep, and communicating with every story. There were three stout floors besides the basement. The basement story was low and gloomy; here the munition and stores for the use of the garrison were deposited. In the north-east angle is a circular winding staircase, communicating from the ground to the summit, and within the south wall is a square passage, or funnel, which also communicates with the upper floors, and from its singularity has given rise to much fanciful speculation; among other conjectures, it has been considered to have been used for the conveyance of stores to the upper part of the keep. On the north side is a flight of steps leading to a dungeon.

The first floor, which seems to have been that occupied by the soldiery, and into which was an entrance from without, was 22 feet in height. Besides 7 large loop-holes, larger than those beneath, there were two spacious conical fire-places, the flues of which gradually contracted to the outer part of the walls, where there were small apertures for the smoke. Another, but smaller fireplace is contained in a little apartment within the north-west angle, and here also were two very curiously-contrived and well-defended win-

dows, designed to command a view of what was passing on the steps of entrance. Within the east floor of this wall is a gallery, together with some private apartments, the openings into which were well calculated to secure those who might be there stationed to watch a besieging army. In the south-east angle is a second circular staircase, which, as well as that in the opposite tower, opens to the top of the building.

The second floor consisted of the state apartments, 28 feet in height, and was more ornamented and lofty than either of the others. These communicated by four large semicircular arches, formed in the partition wall, which was sustained by massive columns and half columns. Within the thickness of the wall round the upper part of this floor is a gallery which traverses the whole keep, and receives light from without through 25 small windows: the exteriors of these were more highly finished than any of the lower openings, and inwardly they appear to have been secured by wooden shutters, the hinges and bare holes of which still remain. This gallery was also open to the state apartments by six arches on each side. The upper floor was about sixteen feet high, and has likewise a gallery, with openings both within and without, similar to the preceding. From the remains of a large arch in the south-east corner it seems highly probable that the chapel was placed here.

The roof of the keep, as well as the floors, have been destroyed: the former, most probably, consisted of a platform on a level with the top of the wall within the parapet: the latter was about five feet high, and had embrasures about two feet wide. The four towers at the angles were raised another story, and had also small platforms with parapets and embrasures. The gutters which conveyed the water from the platform still remain.

The outward walls, which formed an irregular parallelogram of about 300 feet in length, were strengthened by several square and round towers embrasured and provided with loopholes and machicolations. On the north-east was the principal entrance, which was defended by a tower gateway with outworks at the sides. (Britton's *Archæological Antiquities*, vol. iii.)

Lincoln castle, also a Norman castle of the first class, was founded about 1068, at the same time with the castles at Hastings, Nottingham, and York. The keep stands on the south side of the castle. The plan is an irregular polygon. The character of this keep resembles Arundel, Tunbridge, and other Norman castles, and is set on an artificial mount, like Clifford's tower at York, the keep at Windsor, and others. The interior of the castle contains six acres and a half.

In Grose's *'Antiquities'* (vol. i. preface, p. 10.) there is an interesting restoration of a Norman castle with the keep in the centre, and surrounded by the inner and outer baillie, showing also a Saxon mount. But we are informed that there is no good authority for this restoration of Dunmington castle. Bedford castle, which was taken by Henry III. 1221, is considered to have been somewhat similarly situated, from the fact of its having been taken in four attacks: first the barbacon, then the outer baillie, then the inner baillie, and finally by mining the tower the besieged capitulated. Nevertheless it is not by any means clear that the form was such as is restored by Grose.

According to Asser's statement, Alfred built castles of wood and stone. Elfried, his daughter, built eight castles in three years. (Henry of Huntingdon's *Hist.* p. 204.) William of Malmesbury describes a stone castle built by Athelstan at Exeter, A.D. 944. William the Conqueror was a great builder of castles. (ib. *Hist.* p. 8.) Forty-nine castles are mentioned in Domesday Book, which notices Arundel as the only one named in the time of the Conqueror. It is said that in the 19 years of Stephen's reign 1115 castles were erected. It is almost unnecessary to remark that the building of such strong edifices, which in the then state of warfare were often impregnable, is a proof of the insecurity to life and property which prevailed. Every feudal chieftain had his stronghold, round which his immediate retainers rallied for the purpose of mutual defence, or to annoy and plunder their neighbours. A very considerable number of old towns of Europe gradually arose around these baronial fortifications, and it is interesting to trace, in the history of many of these communities, the progress by which the town, originally a miserable dependence on the castle, gradually obtained privileges, and charters, and wealth; and increased in strength and importance exactly in proportion as the owner of the fortress

lost both: till finally the castle, from being neglected and deserted, was either levelled with the ground and furnished materials for house-building, or remained in ruins, an enduring monument of the slow but certain victory of the once subject townsmen over their lords.

We may conclude this article with a brief notice of a few of the remarkable castles still remaining.

Chun Castle, Cornwall, most probably an early British castle, is circular in its form. The plan consists of two concentric circles, raised on a slight artificial mound. Launceston Castle, probably of the same date, has a circular keep or citadel, surrounded by an outer circular wall, both placed on the summit of a conical rock. Fortifications of a later date have been formed at the base of the hill, with works connecting these with the earlier circular works on the summit of the rock. There are some curious castles in the north of Scotland, called Duns. Picts Castle, in Shetland, is a good example. They appear to have been conical, and to have had galleries in the walls.

Oxford Castle seems to have been a Saxon or Norman keep, erected within an earlier circular enclosure, like Chun Castle. Comsborough keep is circular, but it has six enormous buttresses, which give it an angular appearance. The general plan of the castle at Old Sarum, near Salisbury, resembles Chun and Launceston.

Hedingham Castle, Essex, has a fine Norman keep of four stories, part of which is in good preservation. The entrance is over a drawbridge, and the access must have been extremely difficult to besiegers. Richmond Castle, Yorkshire, has also a fine Norman keep-tower. Kenilworth Castle, which encloses an area of seven acres, is built on an irregular plan; but the keep, like that of most Norman castles, seems to have been nearly in the centre of the enclosure. Of the later brick castles, among the most interesting are Tattershall, Hurstmonceux, Thornbury, and Caistor. Tattershall, in Lincolnshire, erected about 1155, is a large square brick tower, with polygonal turrets at the angles. Hurstmonceux, in Sussex, is a brick castle, also with polygonal turrets at the angles and sides, and is similar in the arrangement of the plan of the external wall to the castle at Rochester. The entrance gate-way forms the keep; it was built in the reign of Henry VI. Thorubury Castle, perhaps the last erected, was begun in 1540.

Caistor, in Norfolk, was erected about 1450, and is remarkable for two very large circular brick towers, at the northern angle, one of which only remains. Beaumaris, Conway, Caernarvon, and Caerphilly Castles, all of great extent, are fine specimens of the style of castellated architecture of the time of Edward I. Of the numerous castles erected at various times in this island, a few are still used as residences. The finest are Windsor Castle, the residence of the king, and Warwick Castle, the residence of the Earl of Warwick; and it will be difficult to find in all Europe any edifices of this class which can be compared with them for magnificence. Berkeley Castle, Gloucestershire, Alnwick, Northumberland, Leeds Castle, Kent, Arundel, Sussex, and some others, are still used as dwelling-houses.

Convenience and magnificence are united in the castles of Harwood and Spofford, in Yorkshire. Naworth, in Cumberland, has equal merits. Corfe Castle, which was strong, and of great extent, was defended as late as the reign of Charles I.: it is now in ruins. Dover Castle, also of great extent, presents specimens of the architecture of every period of castellated building.

Few parts of Europe contain so many ruins of castles as the banks of the Rhine. They are almost all built on an irregular plan, and adapted to the nature of the rugged sites on which they are placed. The most remarkable both for their size and history are the castles of Ehrenbreitstein and Heidelberg.

There are many ruins of fine castles in Normandy and in the Pays des Vosges. Switzerland has also its castles, but they are on a smaller scale. The French castles were often bastilles, like Villebon, the castle of the Duke de Sully.

For general information on castles, the reader may consult King's *'Munimenta Antiqua'*; and also the drawings and prints of castles in the king's library of the British Museum. We are indebted to Mr. Britton for permission to consult the numerous drawings of castles (plans and elevations) which he possesses. Grose's *'Antiquities'*; Conybeare's *'Warwick Castle'*; *'The Military Antiquities of the Ro-*

mans in Britain', by the late William Roy; and Britton's *'Archæological Antiquities'*, are our chief authorities.

For further information on castles the reader is referred to Dallaway's account of castles in his *'Discourse on Architecture in England'*; *'Ancient Castles of England and Wales'*, engraved by W. Woolnoth, with descriptions, by E. W. Brayley, jun.; and notices of castles in the *'Archæologia'*, and *'Gentleman's Magazine'*.

CASTLE-MARTYR, a village of 830 inhabitants, in the barony of Imokilly and county of Cork in Ireland, formerly returned two members to the Irish parliament, for which Richard Earl of Shannon received 15,000*l.* compensation at the union. The village, which is a borough and has a charter-school, is the property of Lord Shannon, who has a fine demesne of 1200 Irish acres adjoining. (*Repts. of Commissioners.*)

CASTLEBAR, the assize-town of the county of Mayo in Ireland, in the barony of Carragh, 146 English miles W.N.W. from Dublin. Castlebar is situated on the river Clydagh which, rising in the little lake of Castlebar, within a mile and a half of Clew Bay on the W., flows N.E. with the Moy, which it meets in Loch Callen, to Loch Conn, an inland lake in the centre of the barony of Tirawley, and thence runs northward to Killala bay by Ballina.

Castlebar as a town is of very recent date. It is stated in the Report of the Commissioners on Bogs in Ireland (1814), that eighty years before that time there was but one cultivated field of about eight acres between Castlebar and the sea; and that forty years before that time the roads to the west of Ireland did not pass the town of Castlebar at all. The castle, which gives its name to the place, was a stronghold of the De Burghos. In the wars of the rebellion of 1641 it was held by Sir Henry Bingham for the Parliament, when, being besieged by Lord Mayo and his son Sir Theobald Burke, on the part of the Irish Catholics, he surrendered on terms of being conveyed with his troops in safety to the next garrison town. Lord Mayo protected his prisoners during three days, but on their arrival at the bridge of Shrule, beyond Ballinrobe, the fury of the insurgents could no longer be restrained, and Bingham, with all his company, was barbarously massacred. After the old lord's death his son Sir Theobald, then Lord Mayo, was tried for the offence by a special commission appointed for that purpose, 17th December, 1652, and being found guilty was shot by their sentence 15th January, 1653. Castlebar was also a scene of conflict towards the end of the rebellion of 1798, when General Humbert, having landed at Killala with a force of not more than 1000 French infantry, reinforced by about an equal number of undisciplined peasants of the country, put to rout 6000 British troops commanded by Generals Lake and Hutchinson, and that so completely that the action has since been generally known as 'the races of Castlebar.' The town hereupon fell into the hands of the insurgents, by whom it was occupied for about a fortnight, till the surrender of Humbert at Ballinamuck (8th Sept., 1798) put an end to the ill-judged expedition, and with it terminated the last of the Irish rebellions.

Castlebar is a borough-town, though the corporation has for some time been defunct, and, prior to the union, returned two members to the Irish Parliament, for the loss of which franchise Richard Earl Lucan received 15,000*l.* compensation. The assistant barrister for the county of Mayo sits twice a year at Castlebar for the trial of civil bills, and petty sessions are held in the town every Saturday by the resident county magistrates. The county gaol is situated within the borough limits, which comprise the town and a space of about a mile round in every direction.

Castlebar has some trade in linens, but the vicinity of Westport, which at a distance of eight miles has the advantages of being a seaport town and the residence of an enterprising proprietor, operates considerably to its disadvantage. The court-house is a mean building, and the charter-school has been converted into a lunatic asylum. Here is a good foot barrack, a new church, a Roman Catholic chapel, a Wesleyan meeting-house, and a county infirmary. Lord Lucan is the chief proprietor. Castlebar is not lighted or watched, and the streets are repaired by county payments. There are three bridges over the Clydagh. In 1831 the town contained 909 houses, was occupied by 1196 families, of which 34 were chiefly employed in agriculture, 515 were engaged in trade, manufactures and handicraft, and 647 not included in either denomination; in all a population of 2987 males and 3286 females, total 6273; com-

prising capitalists, bankers, and other educated men, 92 persons. The population in 1821 was 3404, the increase in ten years being 969, or one-seventh. In 1824 Castlebar contained two Protestant and nine Roman Catholic schools, educating 520 males and 235 females; and by Second Report of Commissioners of Public Instruction in Ireland it appears that in 1834 there were in the benefice of Aglish or Castlebar (total population of the three parishes comprised therein 24,464) 14 schools, educating 1000 males and 626 females. Three of these schools were in connection with the National Board of Education, one in connection with the Ladies' London Hibernian Society, and the great majority situated in and near the town of Castlebar.

(Carte's *Ormond*; Inglis's *Ireland in 1834*; *Parliamentary Reports and Papers*; Barrington's *Rise and Fall of the Irish Nation*.)

CASTLETON. [CASTLE.]

CASTINIA, a genus of lepidopterous insects. [SPHINGIDÆ.]

CASTOR (zoology). [BEAVER.]

CASTOR, or a Gemminorum, one of the bright stars in the head of the twins from which the constellation gets its name, being the nearer of the two to the pole. [GEMINI.] This is a remarkable double star, that is to say, consists of two stars so close together as to be inseparable to the naked eye, which are nearly equal, and compose the appearance of the third magnitude. The two are, however, easily separated by a moderately good telescope, being more than four seconds distant from each other at present. Sir J. Herschel has determined the elements of the orbit in which each star moves round the other. (*Mem. R. Astron. Soc.*, v. p. 196.) He calls the star 'the largest and finest of all the double stars in our hemisphere, and that whose unequivocal angular motion first impressed on my father's mind a full conviction of the reality of his long-cherished views on the subject of the binary stars.' By observations of Bradley and Pound, Maskelyne, W. Herschel, Professor Struve, his own, and Sir J. South, he has deduced the following elements of the elliptic orbit of each star round the other; major semiaxis, $8''\cdot086$; eccentricity, $\cdot7582$; inclination of the real orbit to the apparent orbit on the sphere of the heavens, $70^\circ 3'$; period of revolution, 253 years; next period of closest approach, A.D. 1855. In the following years the distances were or will be as follows: at the beginning of

A.D.	Dist.	A.D.	Dist.	A.D.	Dist.
1833	$4''\cdot82$	1845	$3''\cdot85$	1851	$1''\cdot36$
1836	$4''\cdot65$	1848	$3''\cdot37$	1853	$0''\cdot93$
1839	$4''\cdot37$	1850	$2''\cdot91$	1856	$0''\cdot68$
1842	$4''\cdot19$	1852	$2''\cdot18$		

The whole of the computations are of approximations as the present state of the subject will allow.

This star seems on the point of undergoing, within the ensuing twenty-four years, a similar remarkable change to that of which γ Virginis has already furnished a striking instance during the last century, and passing from a distant double star of the second class to a close one of the first, and ultimately to one of extreme closeness and difficulty, such as only the very finest telescopes, with all the improvements we may expect in them, will be capable of showing otherwise than single.

CASTOR FIBER (Linn.), the Beaver. Into a cavity situated at the posterior part of the trunk, both in the male and female animal, the urinary organs and anus open, and in this are also lodged two pear-shaped bags, which receive the secretion of certain glands, which is termed castor. The bags are united by a ligament supposed to be their excretory duct. The secretion is at first in a liquid state about the consistence of syrup, but it ultimately becomes solid, losing some of its odour and activity. As met with in commerce it is of two kinds, the Russian, and Canadian or English, of which the Russian is the rarest and most esteemed: it is more carefully managed from the time of its excision, being first dried in smoke, and often wrapped in swine's bladder. The bags of Russian castor are in pairs of unequal size, from 3 to 4 inches long, and $1\frac{1}{2}$ to 2 inches broad towards the base, the skin thick, smooth, of a brownish red or yellow, the mass more or less friable or tenacious according to age; adhering to them are in general the remains of the oil or fat-bags. The odour is peculiar, very penetrating, and unpleasant; the taste is also peculiar, bitterish, somewhat acrid or aromatic, and enduring. The bags of American castor are smaller, narrower at the base, of a great variety of co-

lours, yellow or orange-brown or brownish-black, the skin thinner, more of the consistence of paper, the surface often wrinkled, and in general no vestiges of the oil-bags present. Both kinds are occasionally slit open and a part of their contents abstracted. A seam on the surface and an internal cavity, sometimes filled with other materials, indicate when this fraud has been effected.

Castor should be kept in a cool place, in a well-corked bottle.

* Brandes, from 1000 parts of Canadian castor, obtained:—

Volatile oil	10.0
Castorine pure	7.0
Castorine with carbonate, urate, and benzoate of lime	3.5
Castoreum-resinoid	120.0
Castoreum-resinoid with benzoate and urate of lime	16.0
Castoreum-resinoid obtained by ether	1.0
Castoreum-resinoid from watery extract	1.5
Albumen with trace of phosphate of lime	0.5
Osmazome-like matter	2.0
Phosphate of lime	14.0
Carbonate of lime	336.0
Carbonate of magnesia	4.0
Sulphate of potassa, sulphate and phosphate of lime	2.0
Animal mucus	23.0
Carbonate of ammonia	8.2
Animal matter	23.0
Skin and salts	192.0
Loss and moisture	229.1

Castorine may be obtained by boiling one part of castor in six of alcohol, and leaving the filtered liquid to cool, when it falls to the bottom. It is very combustible, and is neither acid nor alkaline; it has a copperish taste. It crystallizes in long diaphanous fasciculated prisms, is insoluble in cold water and cold alcohol, but dissolves in 100 parts of boiling alcohol, also in the volatile oils. Bizio considers it the active principle of castor, but it is more probable that the active properties depend upon the essential oil and resinoid principle: the most proper menstruum to take up these is alcohol or the ethers. Rectified spirit is preferable to proof spirit to form the tincture. The compound tincture of the Edinburgh Pharmacopœia is a valuable form of exhibition. It should never be prepared as an extract or a decoction. The powder is not an objectionable form, if too high a temperature be not employed to dry and render it friable.

If from five to ten grains of castor be received into the stomach, a gentle heat is felt in that organ; a more considerable dose causes a still greater sense of heat, and increased strength and frequency of pulse. That the principles of castor pass into the blood is proved by the secretions acquiring its odour during the employment of it internally. It appears to act specially on the cerebro-spinal and ganglionic systems of nerves, so as to modify their condition. Hence it is used against spasmodic symptoms, and to restore the healthy action of the nervous system when that is disturbed. It is rarely given to excite the digestive organs, the heart, or the lungs, but chiefly to influence the brain, the spinal chord, and the uterus. Its employment is sometimes followed by very profound sleep, which, if the dose be moderate, need not excite alarm. Castor is most useful in hysteria, hypochondriasis, nervous palpitations of the heart, convulsive hiccup, colic, and similar diseases. It ought not to be employed if any morbid sensibility of the stomach or enlargement of the heart exist.

CASTOR OIL. [CROTON.]

CASTRES, a town in France, in the department of Tarn, on the river Agout. It is 365 miles from Paris, in a straight line nearly due S.; in $43^\circ 36'$ N. lat., and $2^\circ 15'$ E. long. In the middle ages this town was remarkable only for an abbey, the heads of which were the lords of the place. It subsequently became (according to some authorities) a possession of the crown, and having been erected into a lordship in favour of the counts of Vendôme, passed from them by marriage to the counts of Armagnac. Upon the death of the last count of Armagnac, it was seized by Louis XI., after which, with one interval, it remained in the possession of the crown. In 1567 Castres was taken and pillaged by the Huguenots, who destroyed the cathedral. It became one of the strongholds of the reformed party, to which the inhabitants were attached; but it was reduced to

submission in the reign of Louis XIII., and the fortifications demolished.

The town is situated on both banks of the river, and has two stone bridges. The office of the subprefect, formerly the episcopal palace, is a magnificent edifice; and the town, according to Expilly (1762), has a number of good public buildings and private houses.

The population of Castres, in 1832, was 12,032 for the town, or 16,418 for the whole commune. The inhabitants are engaged in a variety of manufactures; linens, woollens, cottons, paper, leather, and copper and brass goods. It is the most commercial and populous place in the department.

In 1316 Castres was made an episcopal town by Pope John XXII.; the diocese was formed of a portion of that of Alby, and included Upper Languedoc; it was abolished at the Revolution, and the town is now included, with the rest of the department, in the archiepiscopal diocese of Alby.

Among the natives of this town may be mentioned Rapin de Thoyras, author of a well-known History of England, and Abel Boyer, also well known by his French and English Dictionary; these were both Protestant refugees; Dacier, an eminent classic; and the Abbé Sabatier.

In the neighbourhood of Castres is a remarkable curiosity, *le rocher tremblant*, or the rocking stone: it is of an irregular figure, somewhat approaching to that of a flattened egg standing on its smaller end. Its greatest girth, which is at about two-thirds of its height from the ground, is twenty-seven or twenty-eight English feet; the smallest, which is at the base, is about thirteen; the height is about twelve feet; and the weight is estimated at 600 quintals of 100 lbs. each. The base is convex in the direction of its longer diameter, so that at each extremity of that diameter it rises eight inches from the supporting rock; along the smaller diameter of the base the stone is supported throughout, so that it is only in one direction that it is susceptible of motion. It requires several smart pushes to put this stone in motion, but when the movement has once commenced, a small force suffices to keep it up. *Le rocher tremblant* is near the corner of the rock which serves for its support, and overhangs it; it is on the top of a hill, at the foot of which is a remarkable grotto that once served as a retreat to St. Dominick. The arrondissement of Castres had, in 1832, a population of 131,134.

CASTRUCCIO CASTRACANI was born about the year 1283. His family name was Italian, but he assumed that of Castracani on his adoption into the family of that name, which was one of the principal of Lucca. When he was 20 years of age, he visited England, where some of the Interminelli, who had been exiled from Lucca as Ghibelines, had settled, and had acquired wealth by trade. Castruccio was admitted into the court of Edward I., and served in the armies of that prince; but having fallen in a quarrel a nobleman of the court, he was obliged to leave England for Flanders where he served under Philip le Bel, king of France, and greatly distinguished himself by his valour and abilities. About 1313 he returned to Italy, and joined the Ghibelines of Pisa, whom he assisted in expelling the Guelphs from Lucca. But Uguccione della Faggiuola, the leader of the Pisans and a soldier of fortune, having made himself tyrant of both Pisa and Lucca, threw Castruccio into prison. In 1316 an insurrection of both Pisa and Lucca drove away Uguccione, and the citizens of Lucca, having liberated Castruccio from prison, proclaimed him chief of their republic. He was young, handsome, and brave, clever and unscrupulous, and he strengthened himself in his place by removing, by fair or foul means, all those who were ill disposed towards him.

He then attacked Florence, which was the stronghold of the Guelph party in Italy. He took Pistoja and completely defeated, at Alto Pascia, the Florentine army under Raymond of Carlonia, a Catalonian mercenary chief, in September, 1325. He then joined the other Ghibeline leaders in inviting the Emperor Louis of Bavaria to march into Italy and complete the subjugation of the Guelphs. The emperor came, and Castruccio became his chief adviser. In 1327 Louis reduced Pisa, and then proceeded with Castruccio to Rome, which he entered by force, and was crowned in the Vatican by the bishops of Venice and Aleria in January, 1328, notwithstanding the excommunications of the pope John XXII. The emperor next assembled a council in which the pope was declared to have forfeited his dignity, and a new pope was proclaimed under the name of Nicholas V. Castruccio, on this occasion, was made Count Palatine.

He had already been acknowledged by the emperor as Duke of Lucca, Pistoja, Volterra, and Lunigiana. He aimed at uniting all Tuscany under his sway, and establishing at the same time the supremacy of the emperor over all Italy, according to the principles of the Ghibeline party. While at Rome he received intelligence that the Florentines had surprised Pistoja, upon which he immediately returned to Tuscany, and on his way made himself master of Pisa, and besieged and took Pistoja, notwithstanding all the efforts of the Florentines to relieve the place. His exertions during the siege brought on an illness of which he died, 3rd September, 1328, at 45 years of age. His death relieved Florence of one of its most dangerous enemies, and gave at the same time a fatal blow to the Ghibeline party in Italy. His children were driven away from Lucca in the following year. Castruccio is acknowledged by Italian historians to have been one of the few Italian chiefs of the middle ages whose ideas soared beyond the narrow circle of municipal ambition, and who entertained enlarged views for consolidating all Italy into one system. His military tactics, the secrecy of his plans, and the quickness of their execution, are also highly extolled. The life of Castruccio by Machiavelli is more a romance than a real biography. Aldo Manuzio the younger has written 'Le Attoni di Castruccio Castracani, Signore di Lucca,' 4to., Roma, 1590, a good work. Tegrini of Lucca has written the life of Castruccio, Modena, 1496, and Paris, 1546; it is also printed in vol. xi. of Muratori, 'Rerum Ital. Scriptores.' Sismondi, 'Histoire des Républiques Italiennes,' a work however decidedly hostile to the Ghibelines in general, may be consulted.

CASUARACEÆ, a natural order of incomplete Exogens, whose branches are in all cases long, drooping, green, and winy, with very small scale-like sheaths, in the room of leaves. The flowers are unisexual, and disposed in verticillate spikes; they have neither calyx nor corolla, are monandrous, and their ovaries are lenticular, with a solitary erect ovule. The fruit consists of hardened bracts, enclosing the small fruits, which are winged. Botanists say that this very small family, which is exclusively Asiatic, Australian, and Polynesian, is most nearly allied to Myricaceæ; but it appears probable that its immediate allies are either still to be discovered, or are extinct. In habit and in their striated stems casuaraceæ are so like arborescent equisetums, that one can hardly resist the conviction that there must be some connection between those plants, although botanists hardly recognize it. The timber of some species forms the hoop-wood of the New South Wales colonists, and is of excellent quality.

[Casuarina quadrivalvis.]

1, male flowers; 2, one of the same; 3, bract; 4, female flowers; 5, section of the cone; 6, capsule; 7, bractlet; 8, seed; 9, embryo; 10, 11, 12, 13, 14, 15, 16, embryo.

Without its

and 11, section

CASUISTRY, the name of a science which professes to give rules for the resolution of doubts of conscience. It was greatly cultivated in the 15th and 16th centuries, especially by the Jesuits, and was calculated to be a very efficient instrument of the crafty policy ascribed to that order. The confessor, who professed himself able to lay down exact rules of conduct, to weigh the merits of two conflicting duties, and decide which was the greater of two sins, had the means of obtaining an almost boundless influence over his penitent. The casuists made a distinction between venial and mortal sins. 'It is a fixed rule among the casuists,' says Stillingfleet, 'that an infinite number of venial sins do not amount to one mortal, and consequently, though they have obliquity in them, they do not put a man out of the favour of God.' The science of casuistry, however, though so liable to abuse that it has been termed, not inaptly, the 'art of quibbling with God,' has been cultivated in the reformed as well as the papal church; and for a specimen of its subtleties we may refer to Bishop Taylor's 'Ductor Dubitantium, or Rule of Conscience.' There is a professor of casuistry in the university of Cambridge, whose lectures however have been discontinued. For a full account of the casuists, see Mayer's *Bibliotheca of Casuists*, divided into three heads: Lutheran, Calvinist, and Roman.

CAT. [FELIS.]

CAT-BIRD. [MUSCICAPIDÆ.]

CAT'S EYE, a species of quartz sometimes used as a gem.

CAT'S-TAIL GRASS, the common name of *phleum pratense*, an agricultural plant, also called Timothy grass. [*PHLEUM.*]

CATACOMBS, subterranean excavations, used as vaults for the burial of the dead. They are found in most parts of the world, but chiefly in those countries which, like Italy, Sicily, and Egypt, offer extensive beds of soft *tufa* or of some other stone which is easily cut, and which yet is adhesive enough not to fall in. The probable origin of many of them is that they were mere quarries, where materials were dug for building; and when spacious caverns were thus made, the adaptation of them as places of interment seems natural and obvious.

The catacombs of Rome, the entrance into which is on the Via Appia, at a short distance from the city, are very extensive, and have evidently been used both as burying places and as places of worship, for Christian altars, inscriptions, and paintings have been found, and in part still exist in these gloomy crypts. The generally received opinion is, that during the persecutions the early Christians retired thither to worship in secret, and that the remains of many thousands of martyrs were deposited there apart from the pagan Romans. The long galleries of these catacombs, which twist and turn in a curious manner, are, generally speaking, about eight feet high and five wide; there are mostly three tiers of graves or cells, running lengthwise,

one above another, along the galleries, and in some instances there are two and even three of these dark galleries, beneath one another. At certain irregular intervals these subterranean passages converge, and then expand into large vaulted chambers, which still look like churches. Although the cross and the monogram of Christ have long been affixed to every accessible corner, and the traditions of the Romish church give the exclusive occupancy of the catacombs to the Christian dead, there seems good ground to believe that the ancient and pagan Romans deposited the dead in them. According to the ciceroni, or guides, taking in their different ramifications, these cold gloomy galleries run for 20 miles under ground, and several recent travellers have stated their length at six miles, confessing, however, that from their having fallen in and become dangerous in many parts it is not possible to penetrate them to any thing like that extent.

The catacombs of Naples, which are cut in tufo under the hill called Capo di Monte, do not differ materially from those of Rome, and their real extent, which is considerable, is liable to the same exaggeration. The entrance into them is rendered horrible by a vast heap of skulls and bones, the remains of the victims of a plague which desolated Naples in the sixteenth century. Some of these passages are almost covered with Christian symbols, and the paintings in one of the large vaulted chambers or churches, though badly drawn, have retained a wonderful freshness of colouring, considering their under-ground damp situation. The spreading palm-tree is a frequent feature in these pictures. At Palermo and at Syracuse there are similar recesses, the catacombs of the latter place being very considerable, while close in the neighbourhood there are plenty of quarries and subterranean excavations that might have been turned to the same uses. In the island of Malta catacombs, of a much more limited extent, are found at Città Vecchia, cut into the rock on which that old town stands. They occur again in the Greek islands of the Archipelago. At Milo (one of the Cyclades) we have seen a mountain completely honey-combed with them, a labyrinth of tombs running through it in all directions. From the *bassa rilievo*, figures in terra cotta, and other works of art found in them, it was evident that these tombs were of a date far anterior to the Christian epoch. In Egypt these subterranean excavations occur in all parts of the country where there is rock, but they have neither the extent nor the form of those of Rome or Naples, at least so far as is yet known. Those of Abousir are no doubt very extensive, and have not yet been fully explored. There are extensive excavations near Alexandria, which appear from the style of the ornamental parts to belong to the Greek period.

The anxiety of the Egyptians to preserve from decay the bodies of their friends and the bodies of sacred animals, may sufficiently account for the number of these excavations, and for their being so well tenanted. For an account of these excavations the reader may consult Belzoni, Salt, Legh, Henniker, or any respectable modern traveller in Egypt. In Peru, and in some other parts of South America, both mummies and catacombs have been discovered. The mummies however are frequently buried in the sand, and the size of the catacombs can bear no comparison with the extent of those of Italy and Egypt.

The catacombs at Paris could not be called catacombs with any propriety until very recent times, when, by a decree of the French government, all the churchyards within the city which had been crammed to a loathsome and dangerous degree, were emptied of their contents, and the skulls and bones sent to the spacious subterranean quarries, where they are now arranged in a manner that is grotesquely horrible.

CATALEPSY, or **TRANCE** (from the Greek *κατάληψις*, literally 'a seizing'), to which is closely allied *extacy*, or the *extatic trance*, is a disease of the nervous system, attended with an abolition of sensation and of intellectual operation, and with a peculiar condition of the muscles of voluntary motion, those muscles retaining during the paroxysm precisely the same position they were in at the moment of the attack, while the action of the heart and the respiratory functions are but little affected. The malady consists of a great disturbance or an absolute suspension of the functions of the animal life, while the processes of the organic life go on with comparatively little change.

A lively description of a person labouring under a paroxysm of this disease has been given by Dr. Jobb:—My

patient, says this physician, who is describing the condition of a young lady who was the subject of this curious malady, "was seized with an attack just as I was announced. At that moment she was employed in nesting; she was in the act of passing the needle through the mesh; in that position the became immovably rigid, exhibiting, in a pleasing form, a figure of deathlike sleep, beyond the power of art to imitate, or the imagination to conceive. Her forehead was serene, her features perfectly composed. The paleness of her colour, and her breathing, which at a distance was scarcely perceptible, operated in rendering the similitude to marble more exact and striking. The position of her fingers, hands, and arms was altered with difficulty, but preserved every form of flexure they acquired; nor were the muscles of the neck exempted from this law, her head maintaining every situation in which the hand could place it, as firmly as her limbs."

This disease is so rare, while it is not unfrequently feigned, that a suspicion has been excited as to the reality of its existence. Without doubt it is often assumed, and that under circumstances which afford no assignable motive for the deception; but still cases are on record, of which that which has just been recited may be taken as an example, which leave no room to doubt that the affection is not invariably simulated, but is sometimes, though not often, a real disease. The disease, when undoubtedly real, is attended with a disturbed state of almost all the functions of the body. There is commonly severe headache, often giddiness, noise in the ears, lassitude, languor, yawning, a disturbed condition of the gastric and intestinal organs, and, more especially, in the male, of the biliary, and, in the female, of the uterine organs. The functions of the spinal cord and brain are at the same time disordered. The whole muscular system is preternaturally irritable or morbid; there is present a long train of symptoms, commonly termed nervous; the intellectual operations are dull and confused, and the temper is mutable and irascible.

During the paroxysm, which commonly comes on quite suddenly, the patient retains precisely the same posture of the body as at the moment of the attack; even the expression of the countenance which existed at that instant remains unchanged as long as the paroxysm lasts: the eyes, whether open or shut, are perfectly fixed, any position in which any part of the body under the influence of the voluntary muscles may be placed, as the head, the trunk, or the limbs, is retained without the slightest deviation: this fixedness and unchangeableness in the attitude giving to the subject of the malady a striking resemblance to a statue.

The countenance during the paroxysm is almost always paler than natural, though it is stated that it has occasionally been observed to be slightly flushed. The skin in general is unusually cold, excepting about the head, where the heat is sometimes even greater than natural, indicating a preternatural determination of blood to the brain, as well as to all the textures that surround it. The action of the heart is so greatly depressed, that it is often altogether imperceptible, and when capable of being distinguished, it is either slow, occasionally below 50 in the minute, or quick and small. The respiration is sometimes incapable of being distinguished, and is never natural; while the processes of secretion and excretion are performed so languidly as to give little or no indication of their existence; and so, the animal functions being abolished, and the organic being performed in so languid a manner as to be imperceptible, the person is sometimes supposed to be actually dead.

After a period of very uncertain duration, sometimes comprehending only a few minutes, and at other times many hours, occasionally as is stated even days, consciousness returns generally with the same suddenness as the attack commenced, the return to consciousness being accompanied with sighing, and followed by pain or confusion in the head, and a sense of lassitude and fatigue. No memory is retained of anything that may have passed during the paroxysm, the very same train of ideas returning when consciousness is restored as were present at the instant it ceased; and even, according to some narratives, the very same sentences which had been suspended by the seizure being pursued at the moment of recovery.

In the most severe form of the paroxysm, sensation, intellectual operation, and voluntary motion are entirely abolished; and when the attack is less complete, consciousness is re-

Still there is no power of making the slightest movement of any part of the body, nor even of producing so much

as an articulate sound; and several striking and even appalling cases of this latter modification of the disease are on record.

The modification of cataleptic disorder which constitutes the affection termed extacy is generally induced by mental excitement, and sustained contemplation of some particular subject, most generally of a religious nature, and more especially when such subjects have raised the passions and engaged the affections. The patient suddenly seems mentally struck or carried away from all external objects, either standing or sitting, in a most excited and impassioned position, with the eyes fixed and open; and sometimes uttering either the most enthusiastic and fervid expressions, or the most earnest denunciations and warnings, or the most absurd exclamations, with the feeling or belief of their reality; and total abstraction from, or unconsciousness of all surrounding objects or persons.

Such of the cases as were not feigned which lately made so much noise in London under the idea of inspiration with 'unknown tongues' belong to this affection: the effects produced by the practisers of animal magnetism upon nervous persons are obviously allied to it; and the faculty of improvisation is rarely possessed but under a state of the system perfectly analogous to it, while few who are endowed with this power are in a state of sound health, or consider their faculty otherwise than as a morbid one.

The hypochondriac, the melancholic, and the hysterical temperaments are by much the most predisposed to this disease, while the paroxysm is commonly excited remotely by some disorder of the biliary and digestive organs, or by a suppression or some irregularity of the catamenia; and directly by some powerful mental emotion.

The treatment of the malady must be different in every different case, according to the particular condition of the system and the nature of the exciting cause. If some derangement of the physical health be the primary cause of the disease, as is almost always the case, the indications of which will commonly be found, if looked for, in the disturbed functions of the brain, the stomach, the liver, the uterus, &c., such remedies must be applied as are calculated to restore these diseased organs to a sound condition; and the treatment must be essentially the same if the intellectual or the moral health or both be deranged; for this latter derangement is almost invariably the effect of physical disease, and is wholly dependent upon it. (Copland's *Dictionary of Practical Medicine*; and Southwood Smith's *Philosophy of Health*.)

CATALOGUE (Astronomy). This is the name given to a list of stars with the means of determining their positions annexed, whether latitudes and longitudes, or right ascensions and declinations. Such a catalogue is not only a register of the stars in question, but also gives the means of computing the effects of precession, aberration, and nutation, and thus finding the absolute place of the star in the heavens at any given time. Another species of catalogue is a register only, being a list of objects which are looked at, not for the purposes of geography or navigation, but as connected with purely physical investigations, such as double stars, nebulae, &c. The places of the objects are only given to such a degree of nearness as will enable the future observer to lay his telescope upon them. We may place in this list all catalogues of comets; and the whole of this second class requires no further description.

Our whole actual knowledge of astronomy, so far as the position of the heavenly bodies is concerned, is contained in the catalogues of stars and the Planetary Tables, the latter of which furnish, not the places of the planets, but the elements by which those places are determined. The names of the principal catalogues will be found in their proper places in the article **ASTRONOMY**, and there would be no use in repeating them here.

A catalogue, such as is now constructed, shows at one given time the places of a number of stars in right ascension and declination, to which are usually annexed various auxiliary quantities to aid in the reduction of the catalogue to another epoch. These, though useful, are not necessary parts, since they might be supplied by each person for himself, whereas nothing could replace an actual observation made at or near the epoch in question. For the instruments employed in the construction of a catalogue see **TRANSIT INSTRUMENT**, and **CIRCLE**. The regular work of an observatory, so far as the stars are concerned, is the incessant observation of their places, with a view not only to amend pre-

ceding results, and to destroy the necessary errors of one observation by the average of many, but also to increase the precision of the stars, which, since accurate catalogues began to be formed, become visible in comparing the results of catalogues of stars, therefore have been increasing in precision in proportion to the number of comparison, or two distant catalogues served to determine the position of the equinoxes and the motions of the stars.

The positions of stars are observed by a method which, in its correctness depend either upon a plumb-line, or a level, or, at the present day, upon a double observation of the star, first, directly; secondly, by means of a telescope, reflected from a surface of mercury. The latitude of the place, and the refractions of the atmosphere, must also be well known. The right ascensions of the stars, relatively to each other, depend upon nothing but the correctness of the instrument employed, and the uniform going of the clock, but the absolute right ascensions of the stars are measured from a fictitious point, the *mean equinox*. The real equinox is the point at which the sun crosses the equator; but as this point moves in the heavens with a motion nearly uniform, but at the same time affected with slight irregularities (Equinoxes, EQUATION OF), the latter are made use of as corrections to be applied when necessary; and astronomers always give the right ascension of the stars as measured from the point at which the equinox would be, if it had its average motion, instead of the real motion. The same fiction is adopted in our measurement of time, which proceeds not according to the real sun, but according to a fictitious body which moves, not in the ecliptic, but in the equator, and not as the real sun moves, but with its average motion. Consequently, the value of the absolute right ascensions of a catalogue depends upon the observer's observations of the sun; these may be wrong, more or less, while his relative right ascensions may be very correct; that is, the differences of his right ascensions may be exact, while his right ascensions may be wrong by the same quantity arising from a misplacement of the equinox.

In the mean while, since it is certain that there are stars which are much better known than any others, it is usual to make these, which are called *standard* stars, the sole regulators of the clock, that is, to presume that all the difference of right ascension which appears between the places of these stars as deduced from the catalogue, and that obtained from observation, is the fault of the going of the clock; which, corrected by these observations, is made to determine the right ascensions of stars which are presumed to be not so well known. The tendency of this assumption is, to make the latter species of stars as well known as the former, after they cannot be by such a method. The observations of the sun, by which even the standard stars must be regulated, are best made at the solstices (from which the equinoxes can be deduced), and of course occur only twice a year. There is in the Nautical Almanac a catalogue of standard stars, a hundred in number, which are reduced and their places given for every ten days throughout the year. This last refinement, namely, the selection and constant observation of a few particular stars, is due to Maskelyne (1790 and 1805); but the celebrated catalogue of Piazzi (1814), though it contains more than 7000 stars, is considered almost as a perfectly standard catalogue.

Looking further back, we find that a preceding epoch began with Bradley, whose discoveries of aberration and nutation enabled him first to reconcile the discrepancies which his predecessors had detected, but could not account for. Flamsteed (whose catalogue was published in 1725) was the first who habitually observed with the transit instrument to the effect of forming a large catalogue. Hevelius (1680) was the first who determined right ascensions, not however by the transit instrument, but by the old method of measuring distances of stars from each other. Tycho Brahe, the restorer of astronomical measurement, furnished the first catalogue in which any material improvement was made upon that of Ptolemy: for those of Albategnius and Ulug Beg hardly merit such a designation. The catalogue of Ptolemy is not formed from observation, but from that of Hipparchus, brought down to the time of the latter by Ptolemy (but erroneous) value of the precession. Delambre found, by taking the value of the precession as given by Ptolemy himself, and reducing his catalogue of stars to the time of Hipparchus, that it

represented the state of the heavens more nearly than given by Ptolemy had done in the time of Ptolemy.

A catalogue of stars, which is not formed from observation, but from that of Hipparchus, brought down to the time of the latter by Ptolemy (but erroneous) value of the precession. Delambre found, by taking the value of the precession as given by Ptolemy himself, and reducing his catalogue of stars to the time of Hipparchus, that it

represented the state of the heavens more nearly than given by Ptolemy had done in the time of Ptolemy. To give them the same idea of astronomy, some idea of what results, we here subjoin the right ascensions of stars observed and predicted, the last column of the catalogue. The hours and minutes of each are the same; we give only the seconds, and fractions of seconds; that is to say, the star is reported to have passed at such an time by the sidereal clock, of which the hours and minutes are the same in all three, and the seconds and fraction of a second vary as follows

Day.		Obs.	at	Greenwich.	Cambridge.	Edinburgh.	Paris.
1835							
Nov. 1	α Piscium	30.05	10.17	30.12	30.15		
	β Piscium	16.00	16.23	16.05	16.07		
Nov. 27	γ Aquarii	53.03	53.09	53.04	53.09		
Nov. 28	δ Piscium	55.68	55.68	55.68	55.68		
Dec. 2	μ Ceti	5.04	5.33	5.04	5.04		
	π Arietis	9.09	9.02	9.09	9.09		
	ζ Tauri	49.64	49.82	49.64	49.64		

We have made no selection, but have taken them as they came. In five instances out of seven, the catalogue lies between the results of the observers.

CATALOGUES. [BIBLIOGRAPHY.]

CATALONIA (CATALUNA in Spanish), a large province of Spain, the most eastern in the peninsula, and bordering upon France, from which it is divided by the Pyrenees. It has the title of principality, and the name of Spain ever since the time of Charles I. (V. of Germany), have been styled princes of Catalonia. At the breaking up of the western empire, the E. parts of Spain were invaded by the Goths and the Alani, from whose joint names, according to some, the country was called Gothaland, by corruption Catalonia, and lastly Catalonia or Catalonia. The Moors occupied Catalonia at the beginning of the eighth century, but Charles Martel, and Charlemagne, drove them beyond the Ebro. About the end of the eighth century, we find the first mention of an Earl of Barcelona. The Earls of Barcelona were at first vassals of the Carolingian emperors, but they afterwards emancipated themselves, and continued to hold the sovereignty of Catalonia and of the county of Roussillon till the middle of the twelfth century, when Ramon Berenguer, the twelfth earl, married Petronila, daughter of Ramon the Monk, king of Aragon. After the death of Ramon and Petronila, their son, Alonso II. was crowned king of Aragon and earl of Barcelona. Catalonia was annexed to the crown of Aragon as a separate principality, with its own cortes, laws, and usages. By the union of the two crowns of Castile and Aragon in the person of Charles I., Catalonia became a province of the Spanish monarchy, but still retained its laws and privileges, which were however encroached upon by Philip II. and his successors. In 1640 a general insurrection broke out in Catalonia against Philip IV., and the insurgents were assisted by the French, who entered the country. The grounds of complaint which led to the insurrection are forcibly stated in a work published in 1641: "Noticia universal de Cataluña, en agravios, opresiones, y desprecios, sujeción en cosas de honra, privilegios, y libertades, valerosas; en alteraciones, tumultos, y debates, disculpada etc., and addressed to the Illustrious and Wise Councillors of the Council of One Hundred of the City of Barcelona." The war of Catalonia continued for many years, during which the Catalonians, growing tired of their French allies, sought to make their peace with king Philip. But the French continued the war on their own account, until, by the peace of the Bidasoa, 1659, Catalonia was restored to Spain, and Roussillon was given up to France. During the war of the Spanish succession, the Catalonians, as well as the Aragonese, took the part of the Archduke Charles of Austria against Philip of France, in consequence of which, Philip having finally triumphed, formally deprived both the Aragonese and Catalonians of their cortes and liberties, by right of conquest. Barcelona however retained in part its municipal privileges.

[BARCELONA.] Under the present administrative divisions of Spain, Catalonia, or *Cataluña*, is a province, or intendencia, containing thirteen comarcas, or districts, and a population according to the census of 1857 of 1,000,000 inhabitants, exclusive of military garrisons, and garrisons, &c. whose number is uncertain. The surface of Catalonia has been estimated by Hassel's *Historical and Statistical Atlas* for 1825 at 572 German square miles, or about 12,286 English square miles. The province has the shape of a triangle, of which the sea forms one side, the Pyrenees another, and the frontier of Aragon, and in a small part those of Valencia the third. The river Noguera de Ribagorza, which flows almost direct S. from the central Pyrenees to the Ebro, divides Catalonia from Aragon; S. of its junction with the Ebro, the latter river continues the demarcation for a few miles, beyond which the territory of Catalonia extends to the S. side of the Ebro, where a ridge called Montsia, which is an offset of the great range of the Teruel and Albaracin mountains in Aragon, enters this southernmost part of Catalonia, and bounds the valley of the lower Ebro on that side. The highest summit of the Montsia, called the Malacima, is 2740 feet above the sea (Antillon *Geografía de España*). S. of this ridge the small river Cenia divides Catalonia from Valencia. The distance from the mouth of the Cenia direct N. to the frontiers of France near the sources of the Noguera is about 160 miles, which is the greatest length of Catalonia; its greatest breadth from the sources of the latter river to the sea-coast near Rosas is about 125 miles.

The Pyrenees throw out numerous offsets, which run in a general S. direction, dividing the basins of the different rivers, some of which flow into the Ebro, and others into the Mediterranean. The principal rivers are: 1. The Ebro, which comes from Aragon and touches Catalonia below Mequinenza, near which it receives the Segre; it then runs nearly due S. and marks for a few miles the boundary between Aragon and Catalonia; after which, bending to the S.E., it crosses the southernmost part of Catalonia, passes by Tortosa and Amposta, and enters the sea by three mouths forming two islands. The navigation of the Ebro below Amposta is interrupted by shoals and rapids, to avoid which, a canal was begun from Amposta to Alfaques, on the sea-coast, where a good natural harbour exists, but the undertaking has been abandoned. 2. The Segre, which rises in the Pyrenees near Andorra, runs S., passing by Urgel, crosses a plain fertile in corn, then receives the Noguera Pallaresa near Balaguer, and farther S. the Noguera de Ribagorza already mentioned, crosses the fine plain of Lerida, and passing by the town of that name, enters the Ebro below Mequinenza. 3. The Llobregat, which rises near Bagu in an offset of the Pyrenees, runs S., receives the Cardener from the N.W., passes through a narrow gorge at the foot of the mountain called Montserrat, and then enters the sea S. of Barcelona. 4. The Ter rises near St. Pau, E. of the Llobregat, runs first S.E. and afterwards due E., passes by Gerona and Torrella, and falls into the Mediterranean near Palamos, where there is a harbour. 5. The Fluviá rises in the Pyrenees near Camprodon, crosses the fertile district called Ampurdan, passes by Olot, and enters the Gulf of Rosas near Ampurias. Besides these, Catalonia is irrigated by numerous other streams, which either fall into the above rivers, or run after a short course into the Mediterranean. The valleys and plains of Catalonia are fertile; but a large proportion of the country is rocky and naturally barren, although the industry of the inhabitants has done much to improve the soil. It does not produce corn enough for its own consumption, and there is also a want of horned cattle; but it produces a considerable amount of wine, which it exports in large quantities. The forests abound with cork trees, which form a considerable article of commerce. At Falset, W. of Tarragona, are mines of lead and antimony. Coal mines have been found in several parts of Catalonia.

The chief wealth of Catalonia is derived from its maritime resources, and its manufactures. Catalonia is the most manufacturing country of Spain. It has manufactures of woolens, silks, lace, leather, paper, iron, brandy, and tencers, &c. The coasts abound with fish. The Catalonians are the best sailors in the Mediterranean. In the most recent war, they disputed the ascendancy on that sea with the British and Venetians. Of late years their commerce has declined, owing in a great degree to the competition of the American colonies. The annual

value of the exported produce of Catalonia is stated by Hassel at 10 millions of reales, or 400,000 £.

1. Tortosa, a town of 16,000 inhabitants, is the chief port of the left bank of the Ebro, and here the river is crossed by a bridge of stone. Tortosa is a fortified town, surrounded by a deep ditch, and is a bishop's see. It has the buildings of some Roman and Moorish remains, and 16,000 inhabitants. The plain around is fertile, and is irrigated by the Ebro for the purpose of irrigation. The chief produce is sugar, and the neighbourhood of Tortosa has salt pits and quarries of stone. 2. Lerida on the Segre, a strong place, with 12,000 inhabitants. 3. Tarragona, the ancient Tarraco, once the capital of the Roman Tarracensis Provincia, which included the greater part of Spain, is built on a hill near the sea, about fifty miles S.W. of Barcelona. It is an archbishop's see, has a fine cathedral, and several remains of Roman antiquity, such as an amphitheatre, a triumphal arch, and a noble aqueduct, which still carries water to the town. It has some manufactories of silks, carries on a trade by sea, and has 11,000 inhabitants. The country around Tarragona abounds with wine. Tarragona is fortified, and is known in the history of the late Peninsular war for the siege which it sustained against the French Marshal Suchet, and the dreadful massacre of its inhabitants when the place fell. 4. N.W. of Tarragona is Reus, a thriving town, which rapidly risen during the last thirty years. It has manufactures of brandy and liqueurs, and 24,000 inhabitants, who carry on a trade by sea through the small port of Salou, which is six miles from the town. 5. Manresa, N.W. of Barcelona at the confluence of the Llobregat and the Cardener, has manufactures of silks and gunpowder, and 18,000 inhabitants. 6. N.W. of Manresa is Cardonn on the right bank of the Cardener, and at the foot of a rock of pure salt more than 400 feet high, and nearly three miles in circumference at the base. The salt is shining, white, and transparent. 7. Farther N.W. is Solsona, with considerable manufactories of woollens and hardware. 8. W. of Manresa, and between it and Lerida, is Cervera, with 5000 inhabitants, and a university, which has been transferred here from Barcelona. 9. Martorel, a commercial town on the sea-coast, sixteen miles N.E. of Barcelona, in a country rich in wine, has manufactories of cottons, silks, lace, and glass, and 13,000 inhabitants. 10. Farther N.E. but inland is Ostalich, a strong place, which commands the road leading from Barcelona into the N. districts of Catalonia. 11. N. of Ostalich is Gerona, on the right bank of the Ter and at its confluence with the Ona. Gerona is a strong place and has sustained many sieges, is a bishop's see, and has 6000 inhabitants. The territory around is one of the best cultivated in Catalonia: it produces corn, wine, oil, and lemons in abundance. 12. Farther up the Ter is Vich, a bishop's see with manufactories of woollens and cottons, and 12,000 inhabitants. In the neighbourhood are found crystalists, topazes, and coloured crystals, which are carried to Barcelona and worked by the jewellers of that city. 13. N. of Vich is Ripoll, with manufactories of firelocks and bayonets. 14. Olot, in the valley of the Fluviá, with 14,000 inhabitants, carries on a considerable transit trade. 15. Figueras, a town and fortress near the French frontiers, has 7000 inhabitants. Much local information concerning Catalonia may be derived from Major Vacani's *Storia delle Campagne e degli Assedi degli Italiani in Spagna, dal 1808 al 1813*, 3 vols. 4to, with an atlas, Milan, 1823-5; a work valuable, not only for its military, but also for its historical and geographical details. The Italian troops were employed chiefly in Catalonia.

The Catalonians are spirited, industrious, and bold; the educated classes are sociable, well informed, and fond of strangers; the lower orders are boisterous and rude; they are industrious and brave, and make excellent guerillas. Their language is a dialect of the Romance language d'Oc, which was spoken at one time all over the south of Europe. It differs however from the Valencian, and has become mixed up with Castilian words. The following is a specimen of it, being the title of an old book of custom-house regulations issued by their Cortes: 'Capítol dels drets y altres coses del general del Principat de Catalunya y comtats de Rosselló (Roussillon) fets en Cortis generals del Any 1481 fins en le Any 1500, y dels drets que per pragament altrament fets y fets per manament dels molt Illustres Senyors Deputats y Oïdors de Comptes y comprovats de sos autenticos originals recordats de l'Archiu de la Secretaria major de la Casa de la Depu-

tatio, y estampas ab annotaciones referencias de Capitolis, &c. Antic Road of Gerona published in the 17th century. Catalonian and Latin Dictionary.

CATAPLASM. A Symplicial. A tree of considerable size belonging to the natural order *Bignonia*, and is included in the genus *Bignonia*. It is a tree having only two perfect stems. It is found in the mountains of North America along the base of the Sierra Nevada, where it grows to a height of 40 to 50 feet with a diameter of 2 or 3 feet. In that state its branches become naked, and the beautiful appearance of the tree is thus lost. The wood is said to be durable, and is of rare occurrence in the gardens of this country. But when it thrives it forms a singularly beautiful tree, hardly exceeding 30 feet in height, and loaded in May and June with immense quantities of large trumpet-shaped white flowers, variegated with yellow and purple. Many such have been seen on the west of London, in the villages of Hammersmith, Chiswick, Engham Green, &c. The leaves usually grow in threes; they have a heart-shaped outline, are downy underneath, and are from 8 to 12 inches in diameter. The pods are from 12 to 15 inches long, tapering, and filled with winged seeds, having a small tuft of hair at the summit. Some of the American botanists have asserted that it is not an actual aboriginal inhabitant of the United States, because it is generally found in the vicinity of Spaniards, Indian encampments, &c.

CATANIA (the ancient *Karava*, *Cátane*), a city in Sicily, the capital of the *Intendenza* or province of the same name. The province is bounded to the N. and N.E. by that of Messina, N.W. by that of Palermo, W. by Calatamisseta, S. by Siracusa, and E. by the sea. It is 55 miles in length from S.E. to N.W., and about 35 in its greatest breadth, and has a population of 295,000, distributed in three districts, Catania, Caltagirone, and Nicosia. The plain of Catania, 20 miles long and 15 broad, is the largest plain in the island, and produces a great quantity of corn. The lower hills and valleys which belong to the mass of *Ætna* produce excellent wine. Oil, silk, and all kinds of fruit are the other chief products of the country.

The town of Catania is on the sea-coast, at the foot of the most S. offsets of *Ætna*, in $37^{\circ} 29'$ N. lat., and $15^{\circ} 5'$ E. long. Though not the largest, it is the handsomest town in Sicily, and has a population of about 45,000. (Ortolani, *Dizionario Geografico della Sicilia*, 1819; Serristori, *Saggio Statistico*, 1833; Neigebaur gives it only 40,000.) Catania was a colony from Naxos in Sicily, which Naxos was founded by a colony from Chalcis in Eubœa. (Thucyd., vi. 3.) Catania suffered greatly in the wars between the Carthaginians and Syracuse, and was afterwards taken by the Romans in the first Punic war, who plundered it of its riches and statues. Among other things, a sun-dial from Catania was sent to Rome and placed on the rostra. In ancient as well as modern times, Catania has suffered greatly from earthquakes and the eruptions of *Ætna*, one of which is recorded by Thucydides (iii. 116) as having taken place B.C. 425; and he mentions another as said to have happened B.C. 475. The great earthquake of 1693 destroyed it, but the town has been completely rebuilt since that time. The streets are wide and regular, and the buildings are handsome, being mostly built of lava, faced with limestone and enriched with marble. The people of Catania in general have a better and more cheerful appearance than those of the other Sicilian towns: there is considerable beauty among the fair sex, and the upper classes are sociable, well informed, and very civil to strangers. Several of their noblemen have distinguished themselves for their love of the arts and sciences. The old palace of Biscevi, in the last century, formed a splendid collection of sculptures, medals, gems, and other antiques. The *Conservatorio* has formed a rich collection in natural history, and has instituted the academy of natural sciences which bears his name, and publishes valuable memoirs. The Canon Recupero, Ferrara, and other learned men who have investigated the phenomena of *Ætna*, have also formed valuable collections. The university, which was founded by Charles of Aragon in 1445, is frequented by about 500 students. A good library, which is open to the public, is in the Benedictine monastery and church of San Giovanni. Catania is, after Malta in Portugal, the largest and finest monastic building in Europe. The monks are wealthy, and have a museum and a gallery of paintings. The cathedral of Catania, dedicated to St. Agatha, is a vast building. The front is ornamented with

granite columns taken from the theatre of the ancient city. In the square before it stands a fountain with an elephant rearing of lava, bearing on its back a granite obelisk. Catania abounds with the most beautiful sights, such as the houses for the blind, a Magdalen, and a school in which the sons of exiles are educated and brought up to various trades. Of the distinguished men of Catania, Mongitore gives a long list in his *Bibliotheca Sicula*. The port of Catania is only fit for small craft, by means of which however a considerable export trade is carried on in wine, corn, oil, almonds, figs, soda, mutton, silk, cheese, macaroni, amber, which is found at the estuary of the river *Giardina*, lava, and snow from *Ætna*, which is sent to Malta. The Catanese say, 'Se Catania avesse porto, Palermo seria morto,' meaning that if they had a good harbour, their city would become far greater than Palermo. Catania has a Gran Corte, or upper tribunal for civil and criminal causes. The town has considerable municipal privileges, which the inhabitants maintain and exercise with spirit and zeal.

Caltagirone, the second town in the province of Catania, is built on two hills joined together by a bridge; it has several palaces, a royal college, a town-house, Monte di Pietà, and about 20,000 inhabitants. Good pottery is made in this place. Caltagirone is a corruption of *Calata Girone*; the word *Calata*, or *Kalat*, is Arabic, and signifies an eminence. There are several towns in Sicily, the name of which begins with *Calata*, as Calatascetta, Calataniusetta, &c., being the names given to them by the Saracens during their sway over Sicily.

[British Museum. Actual size. Silver. 260 grains.]

Nicosia is built on a mountain, with 12,000 inhabitants, who live chiefly by agriculture. The neighbourhood abounds with mineral water, and has a mine of rock salt. (Neigebaur.) Aci Reale stands on a lava rock, which projects into the sea at the E. base of *Ætna*; with a castle above it on a higher cliff, which forms a little town by itself. Santa Venera is the protectress of Aci. Paternò, the ancient Hybla Major, which gives the title of prince to a Sicilian family, who are the richest landholders in Sicily, has 10,000 inhabitants, many convents and churches, and a fruitful territory. Aderno, at the S.W. base of *Ætna*, has 6000 inhabitants; and San Filippo d'Argiro, the ancient Agryium, has 7000. The other towns are Traina, Nicolosi, and Bronte.

CATAPLASMS, or poultices, are substances applied externally to different parts of the body, either to allay pain and repress inflammation, or more frequently to promote inflammation or its consequences, and lessen the pain attending it. For the former purpose they are applied cold and generally contain a preparation of lead; for the latter they are of different degrees of temperature. When it is intended to hasten the progress of inflammation, so as to lead to suppuration, poultices should be of as high a temperature as the part will bear, but of a lower temperature when they are used as mere emollients. The material of which the poultice is made influences its action, but those are best which have the power of retaining heat and moisture for the greatest length of time. The most of linseed, especially if the oil has not been expressed previous to reducing the seeds to powder, is the best for an common purpose; but John F. has explained that this, and all poultices, were generally made too thin. For application to a limited space, such as the tip of the eye, a roasted apple or fig is best; and a roasted onion is the most suitable application to a boil. Poultices are seldom changed with sufficient frequency. A fresh poultice should always be applied before the one before it has become cold, when the object is to expedite the maturation of a swelling, and bring about suppuration. When the surface is broken and suppuration has set in, it is not necessary to change the poultice so frequently, as it is desirable to exclude the air as much as possible. To cleanse ulcers, the carrot poultice is a good

application, and when there is much irritability or fever, the yeast poultice, or one containing charcoal finely powdered, is best. The face of a poultice is often coated with oil, and sometimes powdered camphor or red bark may be sprinkled on it, according to the affection view.

CATAPULTA. [ARTILLERY, p. 418.]

CATARACT (Gr. *καταράγας*, in its most common sense, 'a fall of water over steep rocks,' also 'a door that shuts to,' 'a bolt, barrier, or obstruction,' from *κατα(ρ)ιμνυμι*, to break down or interrupt), is an opacity of the crystalline lens or its capsule, which obstructs the transmission of light to the retina, and, according to its degree, impairs or destroys the sight.

To understand its nature, and the means adopted for its cure, the following anatomical facts must be borne in mind. The *cornea* or front of the eyeball is a tough, transparent, and slightly protuberant shell, firmly united to the *sclerotic* coat or white part of the eye. Immediately behind the cornea is a space filled by a watery fluid, the *aqueous humour*, in which the *iris* is suspended like a screen. This membrane, attached by its outer edge to the sclerotic near its junction with the cornea, has the power of contraction and expansion, so as to limit the admission of light through its central opening called the *pupil* to the amount best adapted for vision. Behind the iris and nearly touching it is the *crystalline lens*, inclosed in a transparent membranous capsule, which is attached to what are called the *ciliary processes* behind the external border of the iris. The narrow interval between the lens and *uvea* or posterior surface of the iris is called the *posterior chamber*; the more ample space which separates the iris from the cornea is called the *anterior chamber*. The crystalline is a transparent sticky substance of high refracting power, firmer towards the centre or nucleus, more soft as it approaches the capsule, to which it very slightly adheres. It is nearly flat in front and swells out behind into a considerable convexity imbedded in a corresponding hollow of the *vitreous humour*. This fluid fills up the remaining space in the globe: it is inclosed in a pellucid membrane termed the *hyaloid*, and seems to consist of water contained in the interstices of a fine cellular structure, which, dividing it into separate portions, gives it a semi-gelatinous consistence. The *obscure expansion* of the optic nerve called the *retina* is placed like a cup with the concavity forwards, namely, directed behind the hyaloid, the edges advancing as far as the attachment of the capsule of the lens; it consequently incloses the whole of the vitreous humour.

The disease we are now in a condition to describe is divided into *true* and *spurious* cataract. The latter term is applied to an obstruction which arises from an opaque film of purulent lymph thrown out by inflammation between the uvea and the capsule, often producing adhesion between these parts, and passing like a gauze blind across the pupil. The usual means which control inflammation in other cases may be used in this, and sometimes effect a cure, but no operation is applicable to it: it may arise from injury, and occurs occasionally in gout and rheumatism and in some forms of secondary syphilis. The autents appear to have considered it all cataracts to be of this nature.

The cataract is of three kinds: *lenticular*, when the opacity is confined to the lens; *capsular*, when the capsule only is affected; and *capsulo-lenticular* when both structures participate in the disease. The term, when used simply, is to be understood of the lens itself.

Lenticular cataract.—An important practical division of this complaint is into the hard and soft kinds. The former is the most frequent, and is the variety usually met with in advancing age. Though called *hard* for the purpose of distinction, it may have any consistence, from that which is natural to the part, or, as, to the tenacity of wax. The opacity generally begins in the nucleus behind the centre of the pupil, and is at first of a bluish-white colour, like milk and water. This gradually spreads towards the circumference, the nucleus in the mean time assuming an amber-coloured or brownish hue, which sometimes becomes as dark as mahogany, and may extend through the whole lens. The firmness of the cataract is found to bear a close relation to the depth of the tint. Both eyes may be affected at once, but hard cataract more commonly begins in one

eye; and after a certain time, from a few months to several years, the other becomes affected in the same manner, and all useful vision is thus gradually destroyed. In this kind of cataract the lens is almost always diminished in bulk, so that after examination it may be seen to be at some distance behind the pupil, the movements of which remain free and unobscured.

Soft cataract is more frequently single, and prevails in childhood, and the middle period of life. In this form of the complaint the lens, instead of shrinking, commonly enlarges, so as to obliterate the posterior chamber, and press the iris forward towards the cornea. Its texture is everywhere changed and softened: it may be converted into a turbid fluid, in which case the more opaque particles are sometimes observed to subside during rest, or it may have the consistence of soft cheese. The opacity, often streaked and mottled at first, is also general from the commencement, and is found to occupy the whole when dilated to the utmost by artificial means.

It varies in shade from a mere cloud to the whiteness of milk; and in the latter case the light is more completely intercepted than by the darkest hard cataract, which always retains a degree of horny transparency, admitting, for instance, the distinction of shade from sunshine, whereas, in the most opaque soft cataract light can hardly be distinguished from darkness.

There is a kind of central opacity more allied to the soft than the hard species, in which the affection is confined to the nucleus, and sometimes circumscribed to a mere speck in its centre, the rest of the lens remaining transparent. This affection is most frequently met with in infancy, if it be not absolutely confined to that age.

Capsular or membranous cataract commonly appears in specks or streaks of a pearly or chalk-white colour, without the bluish tint which prevails in the early stages of both the former kinds, and more frequently affects the anterior layer of the capsule than the posterior. In the former situation it is close to the pupil, and is plainly convex; in the latter it is concave, but is not so readily distinguished, as it lies deeper and is seen through the lens, itself usually opaque at the same time: indeed some have doubted the separate existence of opacity in the posterior layer of the capsule, and it is certainly by no means so frequent as in the anterior layer.

Capsulo-lenticular cataract, or that in which both structures are implicated, is much more common. In such cases the lens is usually in the softened state already described. Congenital cataracts are generally of this nature: the opacity, if not central, being uniformly diffused, and the consistence never greater, and usually much less, than in the healthy state. It frequently prevails among members of the same family; and has a peculiarity which renders an early performance of the operation of essential importance. This consists in a constant rolling and unsteady motion of the eyeball, which may become habitual, and preclude the patient from ever acquiring the power of directing the eyes at will towards an object. The capsular varieties, especially those which commence in the anterior layer, are more frequently the result of injury, and complicated with inflammatory conditions of the constitution or of the eye itself, than those in which the opacity is confined to the lens. These last, especially the hard cataracts of advanced life, are often strictly local affections, and can neither be classed with inflammatory disorders, nor traced to any constitutional cause.

The symptoms experienced by a person affected with cataract may readily be imagined. The symptom first perceived is a dim haziness of sight, as if a mist or a thin veil were interposed between the object and the eye. The obscurity is greatest in direct vision; in hard cataract, because the opacity is originally central; in soft, because the direct rays pass through the thickest part of the lens, while those which enter laterally are transmitted nearer to the edge, which is comparatively thin. The sight is better, for the same reason, in weak light, and with the back turned to the window, than in strong light; for the pupil in the latter case is contracted, and the rays only of the middle of the lens are admitted, the advantage derived in all cases from drops of the belladonna or dead nightshade in order to dilate the pupil by the action of the belladonna, which with some of the remarkable properties of dilating the pupil by its independent of the retina. It is a curious circum-

* Of 500 cataract patients, treated by Dr. Pabini 268 w. - ages and genders. The following were as follows:—From 1 to 10 years, 14; 10 to 20, 21; 20 to 30, 18; 30 to 40, 41; 40 to 50, 51; 50 to 60, 102; 60 to 70, 172; 70 and upwards, 109. Total, 500.

stance that this effect is not secured by cataract.

None of the varieties of the cataract are subject to the influence of any known medicinal remedy, whatever it may have been put forward; nor is it likely that any remedy exists which is powerful enough to act on so obscurely organized, and so completely diseased, the circulation. No vessels have ever been discovered in the lens under any condition of that part; and it is probably as little endowed with vitality as the hair and nails. Consequently, all the palliation and cure admits of is limited to the local application of belladonna, attention to the general state of the health, and care in removing the inflammatory symptoms, with which, as we have seen, it is sometimes complicated. A radical cure can only be sought about by the actual removal of the cataract.

Much difference of opinion existed as to the most eligible way of effecting this; but it is now well understood that each of the methods proposed may be the best in its turn, and that the point can only be determined by the circumstances of the particular case.

All the operations for cataract may be classed under three, as they are calculated to effect, either its extraction; its displacement from the axis of vision; or its absorption or solution.

Extraction is commonly effected in the following manner:—A fine triangular knife, sharp at the point and the oblique edge, and having the back in a straight line with the handle, and the flat of the blade towards the eye, is steadily and quickly passed through the upper or lower half of the cornea as near to the iris as possible without touching it. A needle slightly curved at the point is insinuated under the flap thus formed, and brought to bear upon the front of the capsule so as to lacerate it; upon gentle pressure of the globe the lens slips out of the capsule, and easily distending the pupil escapes through the wound in the cornea, which soon heals in favourable cases, and the sight is restored. Spectacles suitably convex must afterwards be worn as a compensation for the refractive power of the lens. This operation is chiefly suited to the hard cataract and the adult age. It is inexpedient in gouty and inflammable subjects, and when the eye is either too prominent or too deep in the orbit.

Displacement of the lens from the axis of vision, which was the method practised by the ancients, is effected in several ways; the most usual is that called depression or couching (from the French *coucher*, to lay down). A sharp needle, with edges which cut a little way from the point, is introduced perpendicularly through the sclerotic, near its junction with the cornea, and consequently behind the lens; the pupil having been previously dilated by belladonna. The point is then brought forward through the lens, which, by a backward and downward movement of the hand, is drawn out of its place behind the pupil, and lodged under it in the vitreous humour. The opaque body being thus removed, the sight immediately returns; but as the lens may partially rise again into its place, it is often necessary to repeat the operation at intervals, which has been done a dozen times with perfect eventual success. The lens does not produce so much irritation in its new situation as might naturally be expected, and it is commonly absorbed in part or wholly in the course of time. This method of operating is not very frequently resorted to in the present day.

The third kind of operation, which is intended to cause the absorption of the lens, or its solution in the aqueous humour, is performed much in the same way; but instead of drawing the needle backward, the operator pushes it in through the cornea to the pupil, and lacerates the anterior capsule. The aqueous humour is thus admitted to act upon the cataract, which perhaps, after several repetitions of the operation, becomes absorbed or dissolved, and vision is thus restored. This mode of operating, with variations which need not be detailed, is generally adopted in soft cataract, and always in congenital cases.

It is not only in the execution of the operation; it must in all cases, and especially in extraction, be preceded and followed by means calculated to prevent inflammation, which often occurs in spite of all precautions, and render the operation worse than useless. It is not without thought expedient to operate on one eye while useful vision

remains in the other; nor by the method of extraction in both eyes at the same time; nor is an operation warrantable when the patient cannot distinguish light from darkness, which is the case that some other cause of blindness exists independent of the cataract; nor if the iris or other membranes in front of the crystalline be disorganized by previous inflammation. Many other cases might be enumerated in which an operation is of questionable propriety. On the whole, however, cataract may thus be cured, and useful or even perfect vision restored in a large proportion of cases. The pain of the operation itself is very inconsiderable, nor does any disfigurement or inconvenience arise if it be skillfully performed.

CATARRH, or CORYZA, that is, catarrh in the strict sense of the term, commonly called cold, consists of inflammation of that portion of the mucous membrane of the air passages which lines the nostrils. Inflammation, though often strictly confined to this portion of the lining membrane, when it gives rise to the symptoms known under the name of common cold, or coryza, is very apt to extend beyond the nostrils, when it produces other diseases which are distinguished by different names: when, for example, the inflammation extends from the nostrils into the frontal sinuses, pain, and a sense of weight in the head being superadded to the symptoms of coryza, the affection is called gravedo, catarrhal headache, or cold in the head; when inflammation extends to the back part of the throat, the affection is called coryza catarrhalis, or catarrhal sore-throat; when to the larynx, laryngitis; and when to the bronchi, bronchitis. [BRONCHITIS.]

The symptoms of coryza are a sense of uneasiness, fullness, heat, and stuffing in the nostrils, frequent sneezing, diminished acuteness or total loss of the sense of smell, together with a slight impediment to the respiration, occasioned by the impeded transmission of the air through the nostrils to the lungs, in consequence of the swelling of the membrane, the degree of the swelling being always in proportion to the severity of the inflammation. [BRONCHITIS.] Though the main seat of inflammation in coryza is always in the lining membrane of the nostrils, yet very constantly a sufficient degree of it extends to the frontal sinuses to occasion some uneasiness there, inducing a sense of fullness, heat, weight, and even pain across the forehead. Occasionally, too, the membrane which lines the tube through which the tears pass into the nose becomes so much swollen that the tears cannot enter it, and consequently flow over the cheek; while the external membrane which is reflected over the eye itself participates in the inflammatory affection, and becomes reddened and painful.

These local disorders are often the only symptoms which exist; but whenever the disease is severe, the system becomes affected, and then to these local symptoms are superadded indications of a general disturbance in the economy. These general disordered functions are uniformly those which indicate a febrile condition of the system, namely, chilliness or coldness succeeded by heat, dryness of the skin, lassitude, stiffness, or a sense of uneasiness, often amounting to pain, in the back and limbs, together with a greater or less degree of headache.

The dryness of the membrane affected, in coryza, the first consequence of inflammation, from the suppression of secretion, gives rise to the irritation, the itching and the sensation of heat in the nostrils, and more particularly at their entrance. Next comes the acrid fluid already described [BRONCHITIS], which flowing upon the upper lip and the anterior portion of the nostrils, irritates and excoriates them, and which, passing by the posterior nares, into the pharynx, and thence upon the epiglottis and glottis, occasions violent cough; and last of all flows the bland fluid, with the immediate subsidence of all irritation. [BRONCHITIS.] The causes of coryza are precisely the same as those of bronchitis.

Of all the diseases to which the human body is subject, catarrh is the most frequent, at least in this climate, which is subject to such sudden and great changes of temperature.

its danger is by no means proportioned to its frequency, is never of itself fatal excepting in the very aged. But inflammation of the nostrils, however slight it may be, spreads to other portions of the mem-

severe, and consequently to occasion serious disease. It is the constant source of bronchitis, it often terminates in inflammation of the substance of the lungs, and it frequently lays the foundation for consumption. Hence whenever there is the slightest appreciable predisposition to disease of the lung, a common cold, in however mild a form it may come on, ought to be attended to with anxious care. Every year many persons apparently in good health at its commencement are dead before its close, in consequence of two or three days' neglect of a cold.

The disease, at first local in its seat, may often be cured at once, or at all events its severity may be lessened and its duration shortened by the application of a local remedy; such as the inhalation through the nostrils of the vapour of warm water, or what, perhaps, is more effectual, the vapour of an infusion of chamomile flowers, or of a decoction of poppy-heads. The steam from these heated fluids should be made to pass through the nostrils for at least the space of a quarter of an hour or twenty minutes at a time. It is important that the temperature of the apartment be maintained uniformly at a moderate degree, about 65°, the sleeping as well as the sitting-room. With a view of determining to the skin, so as to produce a general and gentle perspiration, the feet, immediately before going to bed, may be bathed for twenty minutes in warm water, and the bed warmed. A tumbler full of wine-whey, or a basin of warm gruel, will promote the perspiration, and under this simple treatment the patient will often arise in the morning without the slightest remains of the disease. A mild aperient may be often added with advantage.

When there is any degree of fever, the treatment must be the same as in bronchitis.

CATARRHACTES. [BOOBY, vol. v., p. 161; PENGUIN.]

CATASTOMUS, a genus of fishes belonging to the abdominal Malacopterygii and family Cyprinidae. The fishes of this genus are peculiar to the rivers of North America, and the species may be distinguished from others of the carp section by their having the lips thick and pendent and crenated or fringed at the edges; the dorsal fin short as in the genus *Leuciscus* (which contains the roach, dace, &c.), and opposite to and above the ventral fins. M. Lesueur describes seventeen species of this genus in the Journal of the Academy of Natural Sciences of Philadelphia.

CATCH, in music, a composition of the humorous kind for three or four voices, which owes its origin to this country, and does not appear ever to have travelled out of it. It is a song of as many verses or couplets as parts. The highest part is first sung through alone; the singer of this goes then to the second part, the second voice takes the first, &c., and thus each performer sings through all the parts in succession, and, generally, three times over. The *catch* depends on the distribution of the words among the performers. This is so contrived that a meaning is given to the lines wholly different from that which appears when they are read in a straightforward manner. The catch in the good old times, was, in most instances, abominably obscene and disgusting. Among other improvements in manners the abolition of such offensive productions deserves to be mentioned here. Some good catches, however, but of later date, by Webb, Calcott, &c., remain, which are exceedingly facetious, and such as may be, and are, introduced at any social meeting with the greatest propriety.

CATCHFLY, a name applied to several plants, which have the property of retaining insects, either by their viscid surfaces, or by some other means. In *Apocynum androsaemifolium*, and some others, they are caught in the hairs that clothe the mouth of the corolla, in *Silene*, by the glutinous substance that exudes from the calyx; in *Dionaea*, by the collapsing of the two sides of the irritable toothed leaves. [*DIONÆA*, or Venus's Fly-trap.]

CATEAU, LE, a small town in France, on the little river Seille or Sella, a feeder of the Escaut. It is on a road from Cambray to Mezieres, 14 or 15 miles from Cambray; in 50° 7' N. lat., and 3° 32' E. long. It belonged formerly to the archbishops of Cambray, one of whom built here a magnificent castle with fine gardens attached. The town long, sometimes called Le Cateau or Le Château Cambresis, relation made, in 1559, a treaty of peace between Henry II. at once, but Philip II. of Spain, which was by no means

er. This town was once fortified scene. It was secured to France in 1679.

In 1832 the town had a population of 5814; the whole commune, of 5946. Shawls, soap, starch, and leather are among the principal articles cured here. Previous to the Revolution there were several convents or monasteries here, besides the parish church.

CATECHISM, almost all our ecclesiastical terms are of Greek origin, and almost all of them may be traced to some word or some expression in the sacred Scriptures. It would perhaps hardly be expected that the word *catechism* should come from a Greek compound word denoting the sound, *κατηχησθαι*, the reverberation of the word, and the reason that this word has been used in ecclesiastical affairs to denote the mode of instruction by question and answer without book, which is properly meant by catechizing, is that Saint Paul has used the word in his First Epistle to the Corinthians, xiv., 19, "that by my voice I might teach the ignorant, *κατηχησθαι*." The word occurs also in other passages of the Sacred Scriptures, denoting instruction in affairs connected with religion.

Catechizing then, etymologically, and according to the primitive usage, is delivering orally instruction in matters pertaining to religion. Whether in this there was any thing in common with the notions which seem to have pervaded some of the ancient systems of divinity, that the mysteries were not to be committed to writing, but only handed down traditionally from age to age, may be doubted, since the practice is, so easily explained on what is a mere common-sense principle. Christianity was to present herself to innumerable persons who could receive its truths by the hearing of the ear, while they were unable to peruse any writings in which it might be presented to them. Such persons there have always been in every Christian community, and we are quite sure that when the Christian missionaries addressed themselves to nations but a little removed from a state of barbarism, this mode of instruction was the only mode in which what it was necessary for them to know could be communicated. In such a state of society also their answers to a few simple questions, which they would easily learn by frequent repetition, would be accepted as a sufficient profession of faith entitling them to baptism, confirmation, or a participation in any Christian ordinances.

What, in the infancy of Christianity, was the mode of communicating the elements of Christian truth to persons of all ages, has become in process of time the mode of making such communications to the minds of children only. The reason is obvious: we have now seldom any adults who come with minds wholly unfurnished with the elements of Christian truth; children are therefore the only persons who now need catechetical instruction. We do not speak of the few instances which society even in this country does occasionally present of persons brought up in utter ignorance of religion and its truths and duties. But children, generally speaking, are now the only persons who need this kind of instruction; and when we use the terms *catechize* and *catechumens*, which last word denotes the persons placed under this mode of religious instruction, we refer them at once to children, and children only. The more wide extension of the ability to read has rendered this mode of introducing to the young the knowledge of Christian principles and duties of less importance, though it is still considered a part of pastoral duty belonging to the Christian minister to catechize the young of his flock, and thus to prepare them for the ceremony of confirmation. To say the least, it is an impressive mode of communicating the elements of Christian truth, and it serves throughout the period of after-life to cement an attachment which it is desirable should always exist between the individuals of a Christian flock and their pastor. The greater extension of the ability to read has also produced another change. Catechisms, originally intended for the use of the instructor have been transferred to the instructed, who have learned in them the answers which beforetime they were wont to have only from the mouth of the teacher. By far the most celebrated among ourselves of these catechisms is that which is incorporated in the Book of Common Prayer, an intimate acquaintance with which is held to be essential to every person who is a candidate for confirmation. Innumerable other catechisms have been printed, both at home and abroad, in some of which, however, though they are called catechisms, we recognize but faintly the impression of the peculiar character of this mode of instruction, they being rather bodies of Christian divinity exhibited in the form of question and

answer. This is the case with the Racovian catechism, which contains the doctrine of the Socinians. This is the case with the Geneva catechism, which exhibits at much greater length than the Racovian, the doctrine of the Christian truth as professed by the pastors of that city. The Assembly of Divines at Westminster, who, at a time when Presbyterianism was predominant in England, were called together to do form and order of Christian profession, put forth two catechisms: a larger, containing a summary of Christian doctrine, with the evidence on which its several parts were supposed to rest; and a smaller, which was intended for the actual catechetical instruction of the young. Both these present a system commonly called Calvinistic.

CATECHU. The inspissated extract of the *Acacia Catechu* is known by this name; but as there are several varieties of this substance, it is probable that it is procured from other species of this genus, as indeed is positively stated by Dr. Wallich, who denies that any catechu is obtained from the *acacia catechu*. Geiger affirms that one variety of catechu is the extract of *nauclea gambir* (Hunter), which however is generally considered to yield a sort of kino. (See Nees von Esenbeck, in Buchner's *Repert.*, vol. xxii., p. 183, and Dierbach, in *Magaz. für Pharmacie*, vol. xvii., p. 106.) Indeed N. v. Esenbeck confidently assigns the *nauclea gambir* as the source of the Bengal catechu, and the *acacia catechu* as the source of most of the Bombay catechu: a statement which receives considerable countenance from the different amount of tannin which they respectively contain, and the difference of their reaction with the salts of iron; their specific gravity also differs, that of Bombay being 1.35, while that of Bengal is only 1.28.

At the season of the year when the sap is most perfectly elaborated, the bark of the *Acacia Catechu* is removed, and the tree cut down, the outer white part removed, and the remaining brown heart-wood cut into such pieces as can be conveniently introduced into a narrow-mouthed vessel; water is poured in, and then boiled down to one-half the original quantity; the further inspissating is conducted in wide earthen vessels. It is then allowed to stand in the sun, frequently turned, and at last transferred to cloths strewed over with the ashes of cow's dung, and cut into four-square pieces, which are then thoroughly dried in the sun. The darker the wood from which it is obtained, the darker the colour of the extract: it has so much the appearance of a mass of earth as to have been once considered such, and called *terra japonica*. The farina or meal of a seed resembling wheat, and called *nachuni*, is often mixed with it, not as an adulteration, but to prevent the soft masses adhering to each other.

Catechu occurs either in irregular pieces or in small cubes, of a dark brown colour; odour very faint; taste powerfully astringent, afterwards bitterish, then sweet. It is nearly completely soluble in water, more perfectly in alcohol. Analysed by Sir H. Davy,—

Bombay Catechu yielded		Bengal yielded	
Tannin	109		97
Extractive	68		73
Mucilage	13		16
Impurities	10		14

The Bombay variety is preferable. It is a valuable astringent, and may be employed either to act immediately on the mucous membrane of the digestive organs, or on remote organs. In all cases of relaxation of the tissues, either accompanied with a flow of blood or increased mucous discharges, or without any obvious discharge, catechu renders great assistance in restoring the parts to a healthy condition. In relaxed uvula or pap of the throat, causing irritation and cough, a portion of catechu melted slowly in the mouth is extremely useful. In diarrhoea, from debility, catechu alone, or combined with prepared chalk and opium, is much employed, though chemists disapprove of the combination, on the ground that an inert tannate of lime is formed. It is found however to be practically advantageous. Where the debility is great, aromatics and cordials may be added, provided there be no inflammatory condition of the intestines, a point which should always be most carefully inquired into before administering astringents. [ASTRINGENTS.]

CATEGORY, the word *karnyopia* (*karnyopai*, to declare, aver), was used by Aristotle to denote a class of things concerning which some one common assertion may be made, or, in other words, which are susceptible of the same predi-

cate. Aristotle, who composed the *Categories*, by the schoolmen, it is not by Aristotle, as the first

edition for the schoolmen, since Ammonius, Simplicius, Boethius, and others, in their commentaries on it, indicate no doubt of its genuineness; and the reason for doubt assigned in the analysis of Aristotle's *Logic* by Dr. Reid in his 'Intellectual Powers,' 1827 (inserted also in Lord James's 'Sketches'), namely, an inconsistency in the doctrine of the book of *Categories*, and that of the books of *Analytics*, is not founded on fact; though such misconception might well occur about the meaning of the first chapters of the *Categories*, in which so much subtle and abstruse definition is occasioned by the Greek language having but one word, *ousia* (*ousus*), to express 'substance' (all the essential and accidental qualities of an object) and 'essence' (all the essential qualities only). Aristotle's frequent mention of the book of *Categories*, and above all, as Mr. Taylor in his translation remarks, the obscurity and difficulty of the sentences, and the involved diction, are evidence that Aristotle is the author. But similar classifications were formed before the appearance of the *Organon*. In a treatise by the Pythagorean philosopher, Archytas of Tarentum, entitled *παι τοῦ παντός* (concerning the universe, or, as Taylor says, universal terms), the arrangements adopted by Aristotle was set forth and discussed. Through Plato, the disciple of Archytas and preceptor of Aristotle, the theory of the Aristotelian *Categories* descended from the school of Pythagoras, in whose system 10 was a number replete with sacred mystery (*Demetrius Pythagoricus*, by Meursius, c. 12; and *Pythagorean Doctr.*, in *Theoretic Arith.*, by T. Taylor, c. 12). The work of Archytas is copiously cited in the commentary of Simplicius on the ten *Categories*. The extant fragments were also published separately in 1571, 8vo., Venice. Archytas and the other Pythagoreans considered these ten universal ideas as the principles of all things—the causes of the universe,—a doctrine which requires for explanation a reference to the Pythagorean and Platonic theory of ideas. By Aristotle and the peripatetics in general they were proposed merely as comprehensive forms of predication, by which the perplexing variety of human ideas were supposed to be conveniently arranged for the use of the dialectician. All the objects and modes of human thought were thus distributed as species under ten *summa genera*, or universal terms, to facilitate a comprehensive survey of the *τὸ πᾶν*, the whole physical and metaphysical world, known and unknown. The names of the ten *Categories*, as enumerated by Aristotle (*Cat.* c. 1, and *Top.* l. i. c. 9) are—1, *οὐσία* or *τὸ ἄρτι*; 2, *πόσος*; 3, *ποιόν*; 4, *πρὸς τί*; 5, *πῶς*; 6, *πότε*; 7, *κίνησις*; 8, *ἔχειν*; 9, *παθεῖν*; 10, *ἔχειν*; which are variously expressed in English by different writers. In Dr. Whately's *Logic* they are rendered as follows: 'substance, quantity, quality, relation, place, time, situation, possession, action, suffering; but to perceive the meaning of the Greek terms, it must be observed what Aristotle comprehends under each of these general designations: *ἔχειν*, for instance, is said to signify the having something attached to the person; to be 'booted, armed' (*τὸ ἔχειν σπαιρὶν τὸ ἐνοπλιεῖσθαι, τὸ ἐπισταθαι*, *Cat.* c. 9); but in the last chapter of the *Categories* eight modes of having are enumerated. The first four *Categories*, namely, 'οὐσία, πόσος, πρὸς τί, ποιόν,' are elaborately explained by Aristotle in four long chapters: the definition of the remaining six is dispatched in a word or two, but the nature and properties of all are more fully defined incidentally throughout the rest of his works. That they are classifications only of words was maintained by some of the ancient philosophers (*Philos. Arrangements*, by Harris, p. 16). Concerning the question whether these universals are real existences or merely names or conceptions, see the remarks on the Realists and Nominalists in Dr. Reid's 'Essays,' c. 5 and 6. In the later ages of Latinity these *Categories* were denominated *predicaments*; the name by which they have since been generally designated in the scholastic works on logic, in which they are usually translated and placed as follows: 'substantia, quantitas, qualitas, relatio, actio, passio, ubi, quando, situs, habitus' and illustrated by the following jargon as an aid to memory:

'Arbor, sex, sexages, patres, triginta, istos, Ruri, eras, mabo, nec tunicator ero.'

*As to the utility of these ten Categories, it may be remarked that they form an essential part of the artificial system of logic, which was rejected as useless by most of the principal philosophical writers of the last three centuries, such as Bacon, Hobbes, Descartes, Locke, Condillac, Reid, Kames, Stewart, Brown, De Stult Tracy, &c. To maintain among the illiterate the reputation of universal knowledge appeared to have been the only purpose to which they were ever applied. They served to support syllogistic argumentation for victory, and supplied a convenient ready-reckoner, by which a prompt solution could be given even to questions beyond the reach of human knowledge, and in reality quite unanswerable. The lovers of satire may turn to Gassendi's 'Exercitationes adversus Aristoteleos,' where the ten Categories are unsparingly treated. The remarks of Hobbes in his *Logic (Opera Philosophica, 4to, 1658)* are no less satirical: 'Fateor me predicamentum usum hactenus non magnum perspexisse; cept opinor Aristotelem libido quendam pro authoritate sua, cum rerum non posset, verborum tamen censum peragendi, p. 16. So the authors of the Port Royal *Logique, ou l'Art de Penser (Nicole and Arnauld)*, p. 21, 'Voilà les dix Catégories d'Aristotele, dont on fait tant de mystères--à dire le vrai, c'est une chose très peu utile--toute arbitraire, et qui n'a de fondement que l'imagination--elle accoutume les hommes à se payer de mots; à s'imaginer qu'ils savent toutes choses, lorsqu'ils n'en connaissent que des noms arbitraires;' and De Stult Tracy, 'Logique,' p. 22, 'Cela n'est utile absolument à rien.' It would be endless to quote similar opinions from the best modern works on the subject. On the other side, among the defenders of the Categories are Monbodo, Harris, Gillies, and T. Taylor. Harris, in his elaborate work on the subject (*Philosophical Arrangements*, p. 34), says 'The doctrine of these Categories is a valuable, a copious, a sublime theory--a theory which prepares us to study every thing with advantage: p. 462, 'There are few theories so great, so comprehensive, so various, as the theory of these Categories: in contemplating them we see whence the sciences and arts all arise--history out of substance: mathematics out of quantity: optics and medicine out of quality and quantity: astronomy, music, and mechanics, out of quantity and motion: painting out of quality and size: ethics out of relation: chronology out of when; geography out of where: electricity, magnetism, and attraction out of action and passion, &c. In the Categories of Kant (*Kritik der Reinen Vernunft*, 7th ed., 1828), the precise boundaries of human knowledge, *a priori*, are professed to be exhibited; these Categories consist of four primordial classes: 1. quantity, 2. quality, 3. relation; 4. modality; each class containing three Categories: 1. unity, multitude, totality; 2. reality, negation, limitation; 3. substance and accident, cause and effect, action and reaction; 4. possibility, existence, necessity.

That, in treating of extensive subjects, some similar methodical classification is very useful and necessary for perspicuity and brevity, is obvious. A tabulated view of Locke's arrangement of Ideas (his Categories, as they are sometimes named) is given to great advantage on a large sheet prefixed to the edition of his Essay in 1828. Among the ancient different names and numbers of Categories were adopted by different sects. by Aristotle and the peripatetics they are variously called καθόλου λόγοι, universal terms; σχήματα κατηγοριῶν, forms or figures of predication; κατηγορητικά, categories; γένη γινώσκτα, the most comprehensive genera; τὰ πρῶτα δέκα γένη, the ten primary genera. Plato reduces them to five; namely, οὐσία, ταυτότης, ἰσότης, κίνησις, ἀκίνησις; substance, identity, diversity, motion, rest. The Stoics made four; namely, ὑποκείμενα, πᾶσι, πρὸς ἑαυτὰ, πρὸς τὰ ἑαυτὰ; subjects, substances, modes of being, relative modes of being. Some philosophers have preferred seven; namely, spirit, matter, quantity, substance, figure, motion, rest: others three, namely, subject, accident inherent, accident circumstantial: others make only two, simply, substance and attribute, or subject and accident. Other philosophers arrange all existent things under the following six Categories:

*Mens, locum, aetas, quies, motus, postura, figura, sonus, cum materia, cunctatum exordia rerum.

Cicero and Quintilian name the ten Categories of Aristotle 'Elementa Dialectica.'

(See Ammonius, *Comment. in Categ. Graec.*, 12 Venice, 1545; same in Latin by Silvanus, Paris, 1 Simplicii *Comment. in Praedict. Aristot.*, fol., 1567; A

sis of Aristotle's Works, by Dr. Gillies, 4to., p. 58, et seq.; Monbodo, *Origin.*, vol. i., p. 317, et seq.; vol. vi., p. 416; and *Boethii Aristot.*, vol. i., pp. 26, 311, 329; 380, p. 106, et seq. in *Cate. Mind.*, vol. ii., on *Aristot. Log.*; Stewart's *Log.*; The *Orga.* by Pacius, 4to., 1605. The English translation by T. Taylor, 4to., 1812, contains the substance of all the chief Commentaries.

CATENARY (from *Catepes*, to remain) is a curve in which a string of perfect flexibility and uniform thickness and density will hang from two points, which we may suppose to be in the same horizontal line, as the nature and properties of the curve will be the same from what it may hang. And all catenaries are similar; to say, let there be any number of such curves formed by chains of different lengths, each of them will be a picture, on a reduced or enlarged scale, of some portion of the longest.

Various properties of catenaries have been investigated, in cases where the thickness or density of the string are variable. See in particular Cremona's translation of Venturoli's *Mechanics*, and Whewell's *Analytical Statics*. We shall here confine ourselves to the most common properties of the catenary, which, with the modifications always required when we come to apply the mathematics of a flexible and inextensible chain to the materials of the architect, is the first step towards the theory of the suspension bridge. Let C and D be the two points of suspension, CAD the chain, of which A is the lowest point, and AB a vertical

passing through it. Let the units be inches and ounces (any others might be used), and let the weight of the chain be k ounces to the inch; let t be the length of chain equivalent to the tension at A, and T that equivalent to the tension at P, a point whose abscissa is x or x , and its ordinate NP or y . Let the length of the arc AP be s , and the angle NTP be θ . Let Aa be made equal to t inches, and through a draw a horizontal line ap . Hence if CA were taken away, and the chain suffered to hang over a fixed point at A down to a , the part DA would not alter its form. And it is the most striking property of the curve, that if the portion DP above any point P were taken away, and the chain suffered to hang over a fixed point at P down to the same horizontal line ap , the part CAP would be maintained by the portion Pp in its position.

The following are the equations which connect T, t, x, y , and θ :

$$T = t + x = \sqrt{s^2 + t^2}, \quad \tan. \theta = \frac{t}{s}$$

$$s = \sqrt{2 \log r + x^2} = \frac{t}{2} \left(\frac{y}{t} + \frac{t}{y} \right)$$

where $\log r$ = base hyp. log. = 2.7182818

$$y = t \text{ hyp. log. } \left(\frac{x}{t} + 1 + \sqrt{\frac{x^2}{t^2} + \frac{2x}{t}} \right)$$

Given the distance between C and D = $2c$, and the length of the whole chain CAD = $2l$, then the value of θ at the point D, supposing a tangent drawn there, must be found by approximating to a solution (θ being unknown) of

$$\frac{c}{l} = \tan. \theta \text{ hyp. log. cot. } \frac{\theta}{2}$$

which might be solved by inspection, if a sufficient table of the values of the second side were formed. The extreme value of θ being thus found, which call λ , t is found from $t = l \tan. \lambda$, and thence the tension at any point of the curve can be found; and AB, which call h , is found from

$h = \sqrt{b^2 + l^2} - l$. The preceding equation may be thus adapted to the common logarithm.

$$7 \times 4342945 = 1000 \text{ common log col. 2}$$

But in practice it would be sufficient to hang up a thin metal rod against two points in a vertical board, in such manner that C D and C' D' should represent the lengths required on any convenient scale. Then A N and A P should be measured for several different points, and

(A N) — should be found for each.

If the catenary were measured at these should all give the same result, namely the value of l ; but as this will not be found to be the case, the values should be taken.

When A B is small compared with C D, λ must be nearly a right angle, and λ very great. The catenary in that case is very nearly a part of a parabola, which it was supposed to be altogether by Galileo. The focal distance of that parabola is the half of l . We have seen people puzzled to know how a horse on a towing-path draws a heavy boat by a rope which appears slack, and even dips into the water. The reason is, that the tension necessary to pull a long rope into any thing like a straight line, is much greater than that which is necessary to move the boat. A full geometrical account of the catenary, with tables, is given in Ware's 'Tracts on Vaults and Bridges,' London, 1822.

CATENICELLA. [CELLARIEA.]

CATENIPORA. [ZOANTHARIA.]

CATERPILLAR, a name given to the larva state of butterflies and moths. As this term is therefore of partial application only, whilst that of larva is applied to the second stage of all insects (*i. e.* that which follows the egg), an account will be given under the latter head. We will now merely notice an ingenious, and we think probable, derivation of the word caterpillar, as given by Mr. Duncan, in Sir William Jardine's 'Naturalist's Library, British Butterflies,' vol. iii. It is as follows: 'The origin of this word is not very obvious, but it no doubt refers to their destructive propensities. The most probable derivation is that which assigns it to the two old French words, *acot*, food or provisions, more recently written *cates*, as in 'Paradise Lost,'

— Alas! how simple to these cates
Was the crude apple that diverted Eve!

and *pillor*, to rob or plunder, whence also we have the word pillage.

CATHARINA, SANTA. [BRAZIL.]

CATHARINA I. of Russia. [PETER THE GREAT.]

CATHARINA II. ALEXIENNA, born in 1729, was the daughter of the Prince of Anhalt Zerbst, governor of Stettin in Prussian Pomerania. Her name was Sophia Augusta von Anhalt. She married in 1745 her cousin Charles Frederic, Duke of Holstein Gottorp, whom his aunt the Empress Elizabeth of Russia had chosen for her successor, having made him Grand Duke of Russia. In adopting the Greek communion he took the name of Peter, afterwards Peter III., and his consort that of Catharina Alexiennna. It was an ill-sorted and unhappy match. Catharina was handsome, fond of pleasure, and at the same time clever, ambitious, and bold. Her husband, although not destitute of good qualities, was greatly inferior to her in abilities, and was irresolute and imprudent. In consequence of many disagreements with his wife, as soon as he came to the throne by the death of the Empress Elizabeth, he talked of repudiating Catharina, who was then living in retirement at Peterhof, a country residence near Petersburg. She, on her part, determined to anticipate him by a bolder movement. A confederacy was formed in which several noblemen, officers, and ladies joined; the regiments of the garrison were gained by bribes and promises; the emperor was arrested, and Catharina was proclaimed sole empress of all the Russians, Peter having been induced to sign an act of abdication, 17 July, 1762. Six days after, the principal conspirators, by a reaction in the army which might prove fatal to them, went to Ropscha, where Peter was kept in arrest; and, while conversing with him, fell suddenly upon him and strangled him. It does not appear that Catharina actually ordered the murder, but after it was done, she showed no sorrow, and she continued her favour to the murderers. In a proclamation which she issued, it was said that the emperor had died of the cold. Catharina was solemnly crowned at

Moscow in 1762. We shall not enter on her subsequent private life, and the scandalous chronicles of her court; these matters have been treated with the utmost minuteness by most of her biographers, and especially by Castner. We shall here speak not of the woman but of the sovereign, and record the principal acts of her long reign, which was a most important one for Russia and Europe. In 1763, on the death of the weak and indolent Augustus III. king of Poland, that country being in a state of exhaustion and confusion, Catharine, by bribing part of the electors and terrifying the rest, procured the election of one of her favourites, Poniatowski, who was chosen king under the name of Stanislaus Augustus. Having accomplished this, she began to interfere in the internal concerns of that kingdom, whose wretched constitution, with its elective crown, turbulent nobility, serf population, and intolerant clergy, afforded her ample opportunities. In fact, some of the parties in Poland courted her support, as they had been in the habit of courting that of her predecessors and of the other neighbouring states for ages before.

The Dissidents of Poland, which was the name given to those who did not follow the Roman Catholic religion, including both Protestants and followers of the Greek church, were placed upon an equal footing with the Catholics by the Pacta Conventa of 1573, confirmed by the treaty of peace of Oliva in 1660. Since this last epoch, however, the Catholics, being the majority among the high nobility, had gradually excluded the Dissidents from the Diet, and annoyed them in other ways. Early in the 18th century the Dissidents applied to Peter the Great, who remonstrated in their behalf, and obtained by his influence more equitable treatment for them. After Peter's death the Polish Dissidents were again deprived of their political and civil rights: they were excluded from all public offices, were forbidden to build any new church, and many of them were exiled or otherwise persecuted. In 1764 Russia, Prussia, England and Denmark, as guaranties of the peace of Oliva, remonstrated with the diet, but to no purpose. In the session of 1766 the Dissidents were finally subjected to the jurisdiction of the Catholic bishops. In the following year they formed an association, which was called the Confederacy of Thorn, for their common protection, and they were joined by a party of Catholics, who were called Malecontents, upon political grounds, and who now advocated the claims of the Dissidents. The latter were also strongly supported by Russia, the population of which being chiefly of the Greek church felt a lively interest in the fate of their co-religionists, who were very numerous, especially in the east provinces of Poland. In 1768 Russian troops entered Poland and surrounded Warsaw. Several members of the diet, and the bishop of Cracow among them, who were most violent against the Dissidents, were arrested by the Russians, and sent into Siberia, where they remained five years. The diet being now intimidated granted the full claims of the Dissidents. But several Catholic noblemen, especially on the south provinces bordering on Turkey, raised the standard of revolt on mixed religious and political grounds, and a civil war ensued in which the king's troops were defeated. The king and senate at Warsaw petitioned the Russian minister not to withdraw the Russian troops on this emergency, a request which was readily complied with. The insurgents on their part applied to the Turks for assistance, and a war between Turkey and Russia, 1769, was the consequence. During four years Poland was ravaged by civil and religious war, and a dreadful pestilence in 1770 completed the miseries of that country. The result of all this was the first partition of Poland concerted between Catharine, Frederic of Prussia, and Joseph II. of Austria, which was effected in 1772, and was sanctioned by a subservient Polish diet. [POLAND.] More than one-third of that kingdom was divided among the three powers. Russia had for a share the governments of Polotsk and Mohilow, which include a great part of Lithuania and Livonia. Meantime the war with the Turks had proved highly successful to the Russian arms both by sea and by land. Romanzow defeated the Turks on the Pruth, and the Russian fleet in the Mediterranean defeated and burnt the Turkish fleet at Tchesme in 1770. By the peace of Kainarji, July, 1774, Azof and Taganrog were ceded to Russia, and Crimea was declared independent of Turkey. Not many years after, the Russians took Crimea for themselves, 1785, and made it a province of their empire. In January, 1787, Catharine set off from Petersburg with great pomp to visit her new acquisitions. Her journey was like

a triumphal procession. She was joined on the road by the Emperor Joseph II., who accompanied her into Crimea, where they concerted measures for a joint war against Turkey. At Cherson on the Dnieper she inspected the docks constructed by her orders, and saw a ship of the line and a frigate launched. Soon after, the Turks and the Swedes, at the instigation of France and England, declared war against Russia. The object of this war was to check the progress of Russia, but the result was quite the contrary. The Turks were defeated everywhere: they lost Oczakow; Suwarrow took from them Ismail by storm in 1790, with a dreadful massacre of the garrison, and another Russian army entered Georgia. By the peace of Yassi, in 1792, the frontiers of Russia were extended to the Dniester. The war between Russia and Sweden had been already concluded by the peace of Wærså in 1790. Meantime the Poles, taking advantage of the war, had shaken off the influence of Russia, and abrogated the articles of the diet of 1775, which had been dictated by Catharine. In 1791 they formed a new constitution, making the crown hereditary, giving greater privileges to the royal towns, and favouring in some degree the emancipation of the peasants or serfs. But this constitution was far from being acceptable to all the nobles; many protested against it, and so did Catharine of Russia as guarantee of the former constitution. Prussia joined Catharine, and the result was a second partition of Poland in 1793, by which Russia took the whole of Lithuania, Volhynia, and Podolia, and the king of Prussia obtained Posen, Gnesen, and the towns of Danzig and Thorn. In 1794 an insurrection broke out at Warsaw, the Russian garrison was almost entirely destroyed, and the gallant Kosciuszko placed himself at the head of the Poles, who fought with the courage of despair. After being successful at first, he was defeated, wounded, and taken prisoner. Suwarrow stormed Praga, the suburb of Warsaw, with a dreadful slaughter of the inhabitants. Warsaw surrendered, the king abdicated, and the third and last partition of Poland took place in 1795. Austria had Galicia, Prussia took Warsaw, and Russia the rest. Poland thus became extinct as a state. Catharine finally annexed Courland also to the Russian empire.

Catharine began now to turn her attention towards France, and had promised to send troops to join the coalition against that country, when, on the 17th November, 1796, she died of an apoplectic fit, after a reign of 35 years. She was succeeded by her son Paul I.

In the internal administration of her vast empire Catharine effected much good. She reformed the judicial system, which was in a most confused state; organized proper courts, and gave suitable salaries to the judges, in order, as she publicly told them, that they might be placed above temptation. She ameliorated the condition of the serfs or peasants. She encouraged instruction, established schools in all the provinces, schools for teachers after the model of those of Germany, and numerous special or higher schools for the military and naval services, for the mining establishment, for the study of medicine and surgery, for oriental languages, &c. &c. She did all she could to promote communication and commerce between the various countries subject to her sway and with foreign states. She was the great regenerator of Russia after Peter I., but with a more enlightened mind and under more favourable circumstances. She began several canals, among others the one called Severo-Jekaterinski, which unites the Wolga to the Dwina, effects thus a communication between the Caspian and the White Sea. She founded numerous towns, docks, arsenals, banks, and manufactories. She employed several learned men, among others Pallas, Falk, Græmin, Blumayer, Billings, and Edwards, to explore the interior and the remotest parts of her empire. Her encouragement of the arts and literature, and the favour she showed to D'Alembert, Diderot, Euler, &c., are well known. Her correspondence with Voltaire has been published, and forms half a volume in the collected edition of Voltaire's works in 69 volumes. These letters

children Alexander and Constantine. But the most remarkable of her works is her instructions to the Commissioners appointed to frame a new Code of Laws for the Russian Empire, which were translated into English by Tatischeff, London, 4to. 1768. For details concerning her administration, see Tooke's *History of the Reign of Catha-*

rine II.; Count Segur's *Mémoires*, and Rulhière's posthumous works.

CATHARINE DE MEDICI was the daughter of Lorenzo de' Medici, Duke of Urbino, the son of Piero, and grandson of Lorenzo the Magnificent, and nephew of Leo X. Her mother, Magdeleine de Boulogne, of the royal house of France, died in giving birth to Catharine, her only child, in 1519. Her father died soon after, and Catharine was brought up under the care of her great uncle Cardinal Giulio de' Medici, afterwards Pope Clement VII. She was remarkably handsome, clever, and accomplished, but crafty, proud, and unprincipled. In 1533 she was married to Henry, second son of Francis I., of France. It was a political marriage, contracted between the pope and the king, who met at Marseilles on that occasion. In 1547, Henry having ascended the throne, on the death of his father and elder brother, Catharine became queen of France. Her influence at court was not very great during the reign of her husband, it being checked by that of his mistress, Diana of Poitiers, and that of the powerful family of the Guises. Catharine had by her husband five sons, of whom three reigned successively over France—Francis II., Charles IX., and Henry III. During the short reign of Francis II., who succeeded Henry II. in 1547, the chief influence at court was in the hands of the Guises, whose niece, Mary Stuart, had married Francis II. But when, by the premature death of this young prince in 1560, his brother Charles IX., then a minor, ascended the throne, Catharine as regent became the real ruler of France, and continued as such after her son had attained his majority. She is therefore accountable for all the mismanagement, corruption, and atrocities of that calamitous reign, and, above all, for the treacherous massacre of the Protestants in August, 1572, which is known by the name of *La Sainte Barthelemy*, because it was perpetrated on the day dedicated to that saint by the Roman calendar. [BARTHOLOMEW, ST.] The king of Navarre (afterwards Henry IV.) luckily escaped, and the Protestants defended themselves in several parts of the kingdom, so that the civil war raged again as fiercely as ever. Charles IX. died in 1574, leaving the state in dreadful confusion. His brother, Henry of Valois, was then in Poland, where he had been elected king by the Diet. As soon as he heard of his brother's death, he left Poland in secret and returned to France, where he was crowned in 1575. Henry III. was, like his brother, a weak and corrupt prince. Catharine had brought up her sons purposely in licentiousness and dissimulation, in order that she might more easily govern them. The reign of Henry III. was distracted by the intrigues of his favourites, of the queen mother, and of the Guises; by the civil wars between Protestants and Catholics, and by the war between France and Spain. Catharine, according to her usual policy, favoured sometimes one party and sometimes the other, for fear that any one of them should become too powerful for her to manage. At last assassination was resorted to again in order to get rid of the Guises. The Duke of Guise and the cardinal his brother were murdered at Blois in December, 1588, by order of the king. On the 5th January, 1589, Catharine herself died at Blois, an object of aversion to all parties. She was one of the worst sovereigns that ruled over France since the times of the Merovingian dynasty. Even her ambition was not of an enlarged kind: it was narrow, wavering, treacherous, and undecided, and it led to no final result. It was the policy of the petty Italian states of the middle ages, rather than one suited to a great empire. The country was in a state of greater confusion at her death than it had been at any time during her sway; the monarchy was near its dissolution, and it required all the address and the brilliant qualities of Henry IV. to rescue it from total ruin. Catharine had only one redeeming quality—her love for the arts and literature, which seems to have been hereditary in the family of Medici. She collected valuable manuscripts, she encouraged artists, and she began the palace of the Tuileries. She was prodigal in her expenditure, and died much in debt. (De Thou, Sully, Brantôme, and the other French historians and biographers.)

CATHARINE OF ARAGON. [HENRY VIII.]

CATHARINE PARR. [HENRY VIII.]

CATHARINE OF BRAGANZA. [CHARLES II.]

CATHARINE HALL, Cambridge, was founded in 1475, by Robert Woodlark, D.D., chancellor of the University and provost of King's College, who endowed it

for a master and three or more fellows. The visitors, who were sent down to the university by King Edward VI., ordained that there should be in the future there should be a proportion to the revenues of the college. The fellows must be natives of England, and there cannot be more than two of the same county at the same time; two of them at least must be in priest's orders, and one in deacon's orders. Whenever a vacancy occurs, the senior who is not in such orders must take them in the course of twelve months (unless a junior loses of his own accord), or he vacates his fellowship. There are also eight bye fellowships, founded by subsequent benefactors; one by Mr. Frankland, appropriated to Coventry School, elected by the master and fellows, under the recommendation of the mayor and aldermen of Coventry; one by Mr. Holway, which is called the conduct-fellowship; and six by Mrs. Mary Ramsden, of Norton, in Yorkshire, with a preference first to natives of Yorkshire, then of Lincolnshire; and in case no such candidates duly qualified offer themselves, the fellowships are open to candidates of any county. Fellows on this foundation are not required to take orders; and all persons are ineligible to these fellowships who are twenty-four years of age. The fellows on this foundation are called Skirne Fellows. Mrs. Ramsden also founded ten scholarships, with the same preference to Yorkshire and Lincolnshire, which are now of the value of 35*l.* per annum each, with chambers rent-free. Mr. Frankland also founded one scholarship of 10*l.* per annum, which is appropriated to a person educated at Tamworth School. Mr. Holway founded two of 6*l.* per annum each, which are appropriated to persons educated at Eton or Merchant Taylors Schools. There are also three scholarships of 20*l.* 14*s.* 4*d.*, eight of 20*l.*, one of 12*l.*, five of 5*l.*, seven of 4*l.*, two of 3*l.* 6*s.* 8*d.*, two of 2*l.* 13*s.* 4*d.*, and two of 2*l.* per annum each, all perfectly open. The chapel-clerk receives 20*l.* per annum and commons, with chambers rent-free. Queen Anne annexed a prebend of Norwich to the mastership of this college. The king is the visitor. In point of patronage, there are but four livings in the gift of the society, viz., the rectory of Coton in Cambridgeshire, those of Gillingham and Trunch in Norfolk, and the vicarage of Ridgewell in Essex; the total annual income of which, according to the 'Ecclesiastical Revenues' Report, is 1158*l.* The present society of the college (1836) consists of 190 members.

Among the eminent persons educated at Catharine Hall, may be reckoned John Bradford the celebrated martyr, Archbishop Sandys, John Stype the antiquary, Ray the naturalist, Dr. Lightfoot the orientalist, Bishop Blackall, Bishop Hoadly, and Bishop Sherlock. The last mentioned prelate bequeathed his valuable library to the college, and founded the librarianship, worth 20*l.* per annum, with rooms rent free; he also considerably augmented the salary of the master's sizar.

Catharine Hall is a brick edifice, situated on the west side of Trumpington Street: the buildings occupy three sides of a court, the east side being open to the street. The chapel, hall, &c. are on the north side of the court; the master's lodge on the south side. The chapel was consecrated in the year 1704. In the ante-chapel is a monument for the lady of Sir William Daves, Bart., master of the hall, and afterwards archbishop of York; that of Dr. John Eachard, another master, who was a benefactor, who died in 1697; and the tomb of Dr. John Addenbrooke, fellow of the college, and founder of the hospital which goes by his name, who died in 1719. (Lysons's *Magna Brit.* for Cambridgeshire; *Cambr. Guide*, and the *Cambr. Univ. Calendar* for 1836.)

CATHARISTES. [VULTURINÆ.]

CATHARTES. [VULTURINÆ.]

CATHARTICS are material agents which cause a transient but special irritation of the intestinal canal, followed by alvine dejections. It is not necessary that these substances should be placed in direct or immediate contact with the mucous membrane of the intestines, either at its upper extremity (the mouth) or at its lower extremity (the rectum); many of them, when applied to the skin, or injected into a vein, will produce the same effect. This irritation is felt at first merely by the mucous membrane, but secondarily it excites the muscular coat so as to increase the peristaltic and vermicular motions of the intestines. The irritation differs in kind and degree. When it affects the membrane merely so far as to occasion a gentle local action, and is followed only by the expulsion of the matter then resting

upon or covering it, without augmenting the quantity or altering the nature of this matter, the agents which produce such effect are termed *laxatives*. But if the action be more considerable, and not only the present contents be expelled by their effect, but also some of the secretions of the canal be increased, and their quality perhaps greatly altered, they are termed *purgatives*; and, according to the particular secretion which they most obviously augment, they receive their appropriate name—*chologogues*, if it be the bile; *hydrogogues*, if merely the serous fluid. Their effects also frequently extend to the whole system. If their action be very violent, they are designated *drastic purgatives*.

To comprehend fully the manner in which cathartics act, it is necessary to direct our attention to the structure and functions of the intestinal canal. This canal extends from the mouth to the rectum, comprising the organ of taste and mastication, of insalivation, the stomach, and small and large intestines. It is lined with a mucous membrane, the folds or plants of which increase its surface, while the follicular glands which it possesses pour out a viscid mucous, a certain quantity of which is essential to the due execution of its office: this quantity is often much increased by certain purgatives, as we see by the glairy mucous stools. Independently of the juices poured from the glands and vessels into the stomach, the duodenum, or upper small intestine, receives the extremity and contents of the gall-duct and that of the pancreas. Many purgatives in their passage stimulate these ducts, and excite the glands connected with them to increased action. Beneath the mucous membrane is the muscular coat, the chief agent in effecting the propulsion of the contents of the canal. It consists of two sets of fibres, the one arranged in a longitudinal direction, the other in a circular manner. The regular and progressive contraction of these is necessary to move the contents of the canal onwards along its course. The contraction of the one resembling the contractions of a worm in its progress, is termed *vermicular*, and the other *peristaltic*. When their contractions do not harmonize, colicky pains are felt, and are of frequent occurrence during the operation of purgatives, many of which powerfully stimulate this coat to action. When the muscular coat has its action inverted, and the contractions take place from below upwards, instead of from above downwards, it is termed the *anti-peristaltic* motion, by which the contents of the intestines are often ejected by the mouth, as happens in ileus and some other diseases. The last coat or serous membrane, called also peritoneal coat, only obeys the laws of the preceding two in respect to its motion or quiescence. In addition to these structures, the intestines receive numerous arteries, and when an irritant affects them, the blood flows thither in increased quantity. The contact of a purgative causes the capillaries to enlarge; the inner surface of the intestines becomes redder, swollen and warmer—a state generally followed by a large increase of the serous exhalation from the extremities of these vessels. Lastly, the nerves of the intestines are mostly derived from the ganglions of the great sympathetic, by which an important connexion and sympathy is kept up between the intestines, the brain, and spinal chord.

All parts of the intestines do not feel in an equal degree the effect of a cathartic irritant. Some purgatives act more on one part than another, but it may be stated generally that the duodenum, the colon, and the rectum are most under the influence of them. Cathartics also differ essentially in their mode of action, as well as in general in dose, according as they are derived from the mineral or vegetable kingdom. All those from the mineral kingdom, with the exception of calomel, are neutral salts, and are in their secondary effect pre-eminently antiphlogistic, while their dose is considerable. Owing to their solubility they are frequently given dissolved in water, which influences their action. Those from the vegetable kingdom have nearly all a more or less foetid odour, which often causes the stomach to revolt, and occasions nausea. Their impression upon the organs of taste is often bitter and very disagreeable. They generally contain a large proportion of bitter and extractive matters, resins, and gum-resins. Their dose is often very small, from a quarter of a grain to a very few grains: hence they are often administered in the form of pill, bolus, or electuary, more rarely dissolved in water, sometimes in wine or alcohol, or in the form of a direct simple or alcoholic. Several of those from the vegetable kingdom may be applied to the skin, and will produce the usual effect

either by rubbing in, as with castor-oil, or when spread on the face of a poultice and applied over the abdomen for a short time. Scarcely any articles from the animal kingdom are used as purgatives, though small and the use of eggs in fishes are deemed laxative. Many fruits, be their state or preserved, such as prunes, are cathartic. The sudden application of cold to the surface of the body frequently has a useful cathartic action.

By the combination of many purgative substances in the same prescription, their effect is rendered more certain, and at the same time milder. It is also frequently very advantageous to combine purgatives with emetics, or with tonics.

With respect to the practical employment of purgatives, general rules only can be given here. There is scarcely any case in which they have not been employed, or at least recommended; but as much injury may result from their injudicious or unnecessary employment, as good from their careful selection and proper application. The circumstances which call for their use are either where an individual, enjoying otherwise sound health, has not that regular action of the bowels which is at once needful for his present comfort, and desirable as a safeguard against disease; or else when the system is labouring under some other malady, the symptoms of which are aggravated by the retention in the bowels of their contents, which, under such circumstances, are very apt to be of an unhealthy kind. But as these states may occur in individuals of every constitution, and may be accompanied, in the latter case, with many other symptoms which require to be taken into consideration, it is obvious that it is not enough that some purgative medicine be administered: an appropriate selection is necessary. Hence in the course of the same disease (for example, during continued fever), though purgative medicines may be necessary through its whole course, very different medicines must be employed towards the latter stage from those at the beginning. No person unacquainted with medicine would think of treating a case of severe fever, where professional assistance could be obtained, but yet in other diseases, or even where there is no disease, unprofessional persons undertake to decide for themselves or others when a purgative medicine is necessary, and what it should be. The late Dr. Reid stated it as his conviction, derived from extensive observation at a dispensary, that one half of the children that died in London under two years of age were killed by mothers and nurses dosing them with rhubarb and magnesia. For very delicate children nothing can be worse than the frequent use of magnesia. Even grown up persons may be injured by it, either by its debilitating action, or by its accumulating in the intestines: a mass weighing six pounds has been found in the intestines of a person who had frequently used it. Drastic purgatives, especially of a resinous kind, such as scammony or cantharides, when frequently repeated, deprive the inner coat of the intestines of its covering of mucus, and excite inflammation, which often terminates fatally. Excessive purging also may result from an over-dose, and plunge the person into such a state of debility as to place him in imminent danger, or even cause death, either immediately or remotely.

habitual constipation certainly requires to be remedied, but this is best done by mild laxatives, diet, and proper exercise. When the fault is in the rectum merely, enemata of warm water or gruel may be used, for a few times at first, to remove and prevent accumulations in this part of the bowel. But even these apparently simple means should not be had recourse to without medical advice, as the nature of the constitution of the individual must be taken into consideration, and certain precautions observed. It is frequently serviceable to confine persons of a scrofulous habit to the house during the use of purgatives, as they are peculiarly liable to be affected by cold before their operation has passed off. The opposite state to constipation, diarrhoea or looseness, is often best treated by purgatives, especially if it arise from the presence of any undigested food, or unhealthy secretions in the intestine. The mucous fever and diarrhoea of children yields to purgatives sooner than to any other means. The same may be said of many spasmodic diseases, especially in children and females; but as in the treatment of these comes its medical superintendence cannot be dispensed with, we do not further remarks on necessary. (Hamilton on Purgative Medicines, 8th ed.)

CATHARTIC. [CASSIA.]

CATHAY. [CHINA.]

CATHEDRAL. Certain churches are called cathedrals

or cathedral churches. They are so called in consequence of having a seat of dignity (a seat) appropriated to a bishop or archbishop. Thus there is the cathedral church of Exeter, the cathedral church of Norwich, the cathedral church of Wells. They have usually also a dean and body of canons or prebendaries, but this is not essential to constitute a cathedral church, nor is every church that has a chapter of canons a cathedral church. [BISHOP and CANON.]

CATHOLIC CHURCH (Roman). Although in ordinary language this name is often used to designate the ruling authority or power in the Catholic religion, as if distinct from the members of that communion, yet the definition which Catholics give of the church is such as to comprehend the entire body of its members as well as its rulers, the flock as much as the shepherds. Thus we hear of Catholics being under the dominion of their church, or obliged to obey it, although it were something distinct from themselves, or as if they were not a part of their church. This preliminary remark is made to explain a certain vagueness of expression, which often leads to misapprehension, and serves as the basis of incorrect ideas regarding the peculiar doctrines of that church—a vagueness similar to what is frequent in writing and speaking on jurisprudence; as for example, where the government of a country is considered as a power distinct and almost at variance with the nation which it rules, and not an integral part thereof.

The Catholic church therefore is defined to be the community of the faithful united to their lawful pastors, in communion with the see of Rome or with the pope, the successor of St. Peter and vicar of Christ on earth.

Simply developing the terms of this definition, we will give a brief sketch of the constitution or fundamental system of this church, under the heads of its government, its laws, and its vital or constitutive principles.

1. The government of the Catholic church may be considered monarchical, inasmuch as the pope is held in it to be the ruler over the entire church, and the most distant bishop of the Catholic church holds his appointment from him, and receives from him his authority. No bishop can be considered lawfully consecrated without his approbation. The dignity or office of pope is inherent in the occupant of the see of Rome, because the supremacy over the church is believed to be held in virtue of a commission given to St. Peter, not as his own personal prerogative, but as a part of the constitution of the church, for its advantage, and therefore intended to descend to his successors; as the temporal power did from the apostles to those who succeeded them in their respective sees.

The election of the pope therefore devolves upon the clergy of Rome, as being their bishop; and it is confided to the college of cardinals, who, bearing the titles of the eldest churches in that city, represent its clergy, and form their chapter or electoral body. The meeting or chapter formed for this purpose alone is called a *conclave*. The cardinals are in their turn appointed by the pope, and compose the executive council of the church. They preside over the various departments of ecclesiastical government, and are divided into boards or congregations, as they are called, for the transaction of business from all parts of the world; but every decision is subject to the pope's revision, and has no value except from his approbation.

On some occasions they are all summoned together to meet the pope on affairs of higher importance, as for the nomination of bishops, or the admission of new members into their body; and then the assembly is called a *consistory*. The full number of cardinals is 72, but there are always some hats left vacant.

The Catholic church being essentially episcopal is governed by bishops, who are of two sorts, bishops in ordinary, and vicars apostolic. By the first are meant titular bishops, or such as bear the name of the see over which they rule; as the Archbishop of Paris, or of Dublin; the Bishop of Cambray or New Orleans. The manner of appointing such bishops varies considerably. Where they are unshackled by the government, the clergy of the diocese meet in chapter, according to old forms, and having selected three names, forward them to the Holy See, where one is chosen for promotion. This is the case in Ireland, Belgium, and perhaps in the free states of America. In most countries however the election of bishops is regulated by *concordat*, that is, a special agreement between the pope and the civil government. The presentation is generally vested in the crown; but the appointment must necessarily emanate from the pope.

The powers of bishops, and the manner of exercising their authority, are regulated by the canon law; their jurisdiction on every point is clear and definite, and leaves no room for arbitrary enactments or oppressive measures. Yet it is of a different character as, generally considered, can perfectly fulfil the inferior orders of clergy, and secure them to the discharge of their duty. In most Catholic countries there is a certain degree of civil jurisdiction allowed to the bishops, judicial powers, in matters of a mixed character; as in relating to marriages, where a distinction between civil and ecclesiastical marriage has not been drawn by the legislator. Some offences connected with religion, as blasphemy or domestic immorality, are likewise brought under their cognizance.

Where the succession of the Catholic hierarchy has been interrupted, as in England, never been established, as in Australasia or some parts of India, the bishops who superintend the Catholic church and represent the papal authority, are known by the name of *vicars apostolic*. A vicar apostolic is not necessarily a bishop—an instance of which we have now at Calcutta—where the vicar apostolic is a simple priest. Generally however he receives episcopal consecration; and, as from local circumstances, it is not thought expedient that he should bear the title of the see which he administers, he is appointed with the title of an ancient bishopric now in the hands of infidels, and thus is called a bishop *in partibus infidelium*, though the last word is often omitted in ordinary language. A vicar apostolic, being generally situated where the provisions of the canon law cannot be fully observed, is guided by particular instructions, by precedents and consuetude, to all which the uniformity of discipline through the Catholic church gives stability and security. Thus the vicars apostolic, who rule over the four episcopal districts of England, have their code in the admirable constitution of Pope Benedict XIV., beginning with the words *Apostolicum ministerium*. The powers of a vicar apostolic are necessarily more extended than those of ordinary bishops, and are ampler in proportion to the difficulty of keeping up a close communication with Rome. Thus many cases of dispensation in marriage which a continental bishop must send to the Holy See may be provided for by an English or American vicar apostolic; and other similar matters, for which these must consult it, could at once be granted by the ecclesiastical superiors of the Mauritius or of China. The nomination of vicars apostolic is solely with the pope.

The inferior clergy, considered in reference to the government of the church, consist mainly of the parochial clergy, or those who supply the place. In all countries possessing a hierarchy, the country is divided into parishes, each provided with a *parochus* or *curate*,* corresponding to the rector or vicar of the English established church. The appointment to a parish is vested in the bishop, who has no power to remove again at will, or for any cause except a canonical offence juridically proved. The right of presentation by lay patrons is, however, in particular instances fully respected. In Italy the parish priests are generally chosen by competition; as upon a vacancy, a day is appointed on which the testimonials of the different candidates are compared, and they themselves personally examined before the bishop in theology, the exposition of scripture, and extemporaneous preaching; and whoever is pronounced, by ballot, superior to the rest, is chosen.

Under an apostolic vicariate, the clergy corresponding to the parochial clergy generally bear the title of *apostolic missionaries*, and have *missions* or local districts with variable limits placed under their care; but are dependent upon the will of their ecclesiastical superiors.

Besides the parochial clergy, there is a considerable body of ecclesiastics, who do not enter directly into the governing part of the church, although they help to discharge some of its most important functions. A great number of *secular* clergy are devoted to the conduct of education, either in universities or seminaries; many occupy themselves exclusively with the pulpit; others with instructing the poor, or attending charitable institutions. A certain number also fill prebends, or attend to the daily service of cathedrals, &c.; for in the Catholic church, pluralities, where the cure of souls exists, are strictly prohibited, and consequently a distinct body of clergy from those engaged in parochial

duties, or holding rectories, &c. is necessary for those duties. Besides this auxiliary force, the regular clergy, or monastic orders, take upon them many of these functions. These institutions, or closely connected with the church, may require an explanation in their proper place. The clergy of the Catholic church, the vast majority of whom are bound by a vow of celibacy, not formally, but implied in their ordination as *sub-deacons*. This obligation of celibacy is only reckoned among the disciplinary enactments of the church. The clergy of that portion of the Greek and Armenian church which is united in communion with the see of Rome, may be married; that is, they receive orders if married, but are not allowed to marry after having taken orders. A similar discipline, if thought expedient by the church, might be introduced into the west.

The only point concerning the government of the Catholic church which remains to be mentioned in the manner in which it is exercised. The most solemn tribunal is a *general council*, that is, an assembly of all the bishops of the church, who may attend either in person or by deputy, under the presidency of the pope or his legates. When once a decree has passed such an assembly, and received the approbation of the Holy See, there is no further appeal. Distinction must be however made between *doctrinal* and *disciplinary* decrees; for example, when in the council of Trent it was decreed to be the doctrine of the church, that marriage is indissoluble, this decree is considered binding in the belief and on the conduct, nor can its acceptance be refused by any one without his being considered rebellious to the church. But when it is ordered that marriages must be celebrated only in presence of the parish priest, this is a matter of discipline, not supposed to rest on the revelation of God, but dictated by prudence; and consequently a degree of toleration is allowed regarding the adoption of the resolution in particular dioceses. It is only with regard to such decrees, and more specifically the one we have mentioned, that the council of Trent is said to have been received, or not, in different countries.

When a general council cannot be summoned, or when it is not deemed necessary, the general government of the church is conducted by the pope, whose decisions in matters of discipline are considered paramount, though particular sees and countries claim certain special privileges and exemptions. In matters of faith it is admitted that if he issue a decree, as it is called, *ex cathedra*, or as head of the church, and all the bishops accept it, such definition or decree is binding and final.

The discipline or reformation of smaller divisions is performed by provincial or diocesan synods. The first consist of the bishops of a province under their metropolitan; the latter of the parochial and other clergy under the superintendence of the bishop. The forms to be observed in such assemblies, the subjects which may be discussed, and the extent of jurisdiction which may be assumed, are laid down at full in a beautiful work of the learned Benedict XIV., entitled *De Synodo Diocesana*. The acts and decrees of many such partial synods have been published, and are held in high esteem among Catholics; indeed, they may be recommended as beautiful specimens of deliberative wisdom. Such are the decrees of the various synods held at Milan under the virtuous and amiable St. Charles Borromeo.

II. The *laws* of the Catholic church may be divided into two classes, those which bind the interior, and those which regulate outward conduct. This distinction, which corresponds to that above made, between doctrinal and disciplinary decrees, may appear unusual, as the term *laws* seems hardly applicable to forms of thought or belief. Still, viewing, as we have done, the Catholic church under the form of an organized religious society, and considering that it professes to be divinely authorized to exact interior assent to all that it teaches, under the penalty of being separated from its communion, we think we can well classify under the word *law* those principles and doctrines which it commands and expects all its members to profess.

Catholics often complain that doctrines are laid to their charge which they do not hold, and in their various publications protest against their belief being assumed upon any but authoritative documents; and as such works are per-

* To avoid mistakes, we may observe that the parish priest in Ireland corresponds to the cure in France, the curato (or, in the country, arciprete) of Italy, and the cura of Spain. The curate in Ireland, as in the church of England, is equivalent to the vicar of France and the *sotto-curato* of Italy.

* The great difference between the Eastern and Western churches, as they are termed, is whether such a power has its force prior to, or independent of, the accession of the body of bishops to it, or whether its sanction and binding power flow from their acceptance. Practically there is little or no difference between the two opinions; yet this slight variety forms a principal groundwork of what are called the liberties of the Gallican church.

fectly accessible, the complaint must appear reasonable as well as just. There are several works in which an accurate account is given of what Catholics are expected to believe, and which carefully distinguish between those points on which latitude of opinion is allowed, and such as have been fully and decisively decreed by the supreme authority of the church. Such are the *Veneranda Regula Fidei*, or *Rule of Faith*, a work lately translated into English, and Holden's '*Analysis Fidei*.' But there are documents of more authority than these; for example, the '*Declaration*' set forth by the vicars and bishops in England, in 1823, often republished; and the '*Catechismus ad Parochos*,' or '*Catechism of the Council of Trent*,' translated into English not many years ago, and published in Dublin. A perusal of such works as these will satisfy those who are desirous of full and accurate information regarding Catholic tenets, their real nature, and show that the popular expositions of their substance and character are generally incorrect.

The formulary of faith, which persons becoming members of the Catholic church are expected to recite, and which is sworn to upon taking any degree, or being appointed to a chair in a university, is the creed of Pius IV., of which the following is the substance:—

The preamble runs as follows: 'I, N. N., with a firm faith believe and profess all and every one of those things which are contained in that creed, which the holy Roman church maketh use of.' Then follows the Nicene creed.

'I most steadfastly admit and embrace apostolical and ecclesiastical traditions, and all other observances and constitutions of the same church.

'I also admit the holy scriptures, according to that sense which our holy mother the church has held and does hold, to which it belongs to judge of the true sense and interpretation of the scriptures: neither will I ever take and interpret them otherwise than according to the unanimous consent of the fathers.

'I also profess that there are truly and properly seven sacraments of the new law, instituted by Jesus Christ our Lord, and necessary for the salvation of mankind, though not all for every one, to wit, baptism, confirmation, the eucharist, penance, extreme unction, holy orders, and matrimony: and that they confer grace; and that of these, baptism, confirmation, and order cannot be reiterated without sacrilege. I also receive and admit the received and approved ceremonies of the Catholic church, used in the solemn administration of the aforesaid sacraments.

'I embrace and receive all and every one of the things which have been defined and declared in the holy Council of Trent, concerning original sin and justification.

'I profess likewise that in the mass there is offered to God a true, proper, and propitiatory sacrifice for the living and the dead: and that in the most holy sacrament of the eucharist there is truly, really, and substantially, the body and blood, together with the soul and divinity of our Lord Jesus Christ; and that there is made a change of the whole substance of the bread into the body, and of the whole substance of the wine into the blood, which change the Catholic church call *transubstantiation*. I also confess that under either kind alone Christ is received whole and entire, and a true sacrament.

'I firmly hold that there is a *purgatory*, and that the souls there detained are helped by the suffrages of the faithful.

Likewise, that the saints reigning with Christ are to be honoured and invoked, and that they offer up prayers to God for us: and that their relics are to be had in veneration.

'I most firmly assert that the images of Christ, of the mother of God, and also of other saints, ought to be had and retained, and that due honour and veneration are to be given them.

'I also affirm that the power of excommunication was left by Christ in the church, and that the use of them is most wholesome to Christian people.

'I acknowledge this holy Catholic Apostolic Roman church for the mother and mistress of all churches: and I promise true obedience to the bishop of Rome, successor to St. Peter, prince of the apostles and vicar of Jesus Christ.'

Then follow clauses, condemnatory of all contrary doctrines, and expressive of adhesion to all the definitions of the Council of Trent.

Under penance is included confession, as the Catholic sacrament of penance consists of three parts: contrition, confession, and satisfaction. The clerical orders of the church are divided into two classes, sacred and minor orders. The sacred orders are, deacon, priest, and bishop. The minor orders are, reader, subdeacon, and porter. The hair is shorn, initiatory to the ecclesiastical state.

It is obvious that this form of confession was in accordance to the decrees of that council, and consequently has chiefly in view the opinions of those who followed the Reformation. It would be foreign to our purpose to enter into any explanation of the doctrines here laid down, much less into any statement of the grounds on which Catholics hold them, as we purposely refrain from all polemical discussion.

Such is the doctrinal code of the Catholic church; of its moral doctrines we need not say anything, because no authorised document could be well referred to that embodies them all. There are many decrees of popes condemnatory of immoral opinions or propositions, but no positive decrees suffice it to say, that the moral law, as taught in the Catholic church, is mainly the same as other denominations of Christians profess to follow.

Of the disciplinary or governing code we have already spoken, when we observed that it consisted of the Canon Law, which, unlike the doctrinal and moral code, may vary with time, place, and accidental circumstances.

III. Our last head was the essential or constitutive principle of the Catholic church. By this we mean that principle which gives it individuality, distinguishes it from other religions, pervades all its institutions, and gives the answer to every query regarding the peculiar constitution outward and inward of this church.

Now, the fundamental position, the constitutive principle of the Catholic church, is the doctrine and belief that God has promised, and frequently bestows upon it, a constant and perpetual protection, to the extent of guaranteeing it from destruction, from error, or fatal corruption. This principle once admitted, every thing else follows. 1. The infallibility of the church in its decisions on matters concerning faith. 2. The obligation of submitting to all these decisions, independently of men's own private judgments or opinions. 3. The authority of tradition, or the unalterable character of all the doctrines committed to the church: and hence the persuasion that those of its dogmas, which to others appear strange and unscriptural, have been in reality handed down, uncorrupted, since the time of the apostles, who received them from Christ's teaching. 4. The necessity of religious unity, by perfect uniformity of belief: and thence as a corollary the sinfulness of wilful separation or schism, and culpable errors or heresy. 5. Government by authority, since they who are aided and supported by such a promise must necessarily be considered appointed to direct others, and are held as the representatives and vicegerents of Christ in the church. 6. The papal supremacy, whether considered as a necessary provision for the preservation of this essential unity, or as the principal depository of the divine promises. 7. In fine, the authority of councils, the right to enact canons and ceremonies, the duty of repressing all attempts to breach new opinions: in a word, all that system of rule and authoritative teaching which must strike every one as the leading feature in the constitution of the Catholic church.

The differences, therefore, between this and other religions, however complicated and numerous they may at first sight appear, are thus in truth narrowed to one question; for particular doctrines must share the fate of the dogmas above cited, as forming the constitutive principle of the Catholic religion. This religion claims for itself a complete consistency from its first principle to its last consequence, and to its least institution, and finds fault with others, as though they preserved forms, dignities, and doctrines which must have sprung from a principle by them rejected, but which are useless and mistaken, the moment they are disjoined from it. Be this as it may, the constitution of the Catholic church should seem to possess, what is essential to every moral organized body, a principle of vitality which accounts for all its actions, and determines at once the direction and the intensity of all its functions.

To conclude our account of the Catholic church, we will give a slight view of the extent of its dominions, by enumerating the countries which profess its doctrines, or which contain considerable communities under its obedience. In Europe, Italy, Spain, Portugal, France, Belgium, the Austrian empire, including Hungary, Bavaria, Poland, and the Rhenish provinces of Prussia, which formerly belonged to the ecclesiastical electorates, profess the Catholic religion as that of the state, or, according to the expression of the French *charte*, that of the majority of the people. In America, all the countries which once formed part of the Spanish dominions, both in the southern and northern portion of the continent, and which are now independent states, profess exclusively the same religion. The empire of Brazil is also Ca-

Catholic Lower Canada and all those islands in the West Indies which belong to Spain or France, including the Republic of Haiti, profess the Catholic faith; and there are also considerable Catholic communities in the United States of North America, especially in Maryland and Louisiana. Many Indian tribes, in the Canada, in the United States, in California, and in South America, have embraced the same faith. In Asia there is hardly any nation professing Christianity which does not contain large communities of Catholic Christians. Thus in Syria the entire nation or tribe of the Maronites, dispersed over Mount Libanus, are subjects of the Roman see, governed by a patriarch and bishops appointed by it. There are also other Syrian Christians under other bishops, united to the same see, who are dispersed all over Palestine and Syria. At Constantinople there is a Catholic Armenian patriarch who governs the united Armenians as they are called, large communities of whom also exist in Armenia proper. The Abbé Dubois, in his examination, before a committee of the House of Commons in 1832, stated the number of Catholics in the Indian peninsula at 600,000, including Ceylon, and this number is perhaps rather underrated than otherwise. They are governed by four bishops and four vicars apostolic with episcopal consecration. A new one has just been added for Ceylon. We have not the means of ascertaining the number of Catholics in China, but in the province of Su-Chuen alone they were returned, 22nd September, 1824, at 47,487 (*Annales de la Propag. de la Foi*, No. XI. p. 257); and an official report published at Rome in the same year gives those in the provinces of Fo-kien and Kiansi at 40,000. There are seven other provinces containing a considerable number of Catholics, of which we have no return. In the united empire of Tonkin and Cochinchina the Catholics of one district were estimated at 200,000 (*Ibid.*, No. p. 191), and, till the late persecution, there was a college with 200 students, and convents containing 700 religious. Another district gave a return, in 1826, of 2955 infants baptized, which would give an estimate of 88,000 adult Christians. A third gave a return of 170,000. M. Dubois estimates the number of native Catholics in the Philippine islands at 2,000,000. In Africa, the islands of Mauritius and Bourbon are Catholic, and all the Portuguese settlements on the coasts, as well as the Azores, Madeira, the Cape Verde, and the Canary Islands.

CATHOLIC EPISTLES is the name given to the Epistles of the Apostles James, Peter, John, and Jude. They are called Catholic, i.e., 'universal,' according to the original meaning of the word, because they are addressed not to any particular church or nation, like the Epistles of St. Paul, but to the faithful in general then scattered about the world. St. James addresses his Epistle to the twelve tribes that are scattered abroad, meaning the converted Jews in Judaea and other Roman provinces. St. Peter addresses his first Epistle to the strangers scattered throughout Pontus, Galatia, Cappadocia, Asia, and Bithynia. St. John addresses the second of his Epistles to the elect lady and her children, meaning the universal church and its disciples; and Jude addresses his to the faithful in general.

CATILINA, LUCIUS SÉRGIVS, descended from an illustrious patrician family, was born about B.C. 109. Catiline was quaestor about B.C. 77, and afterwards served as legatus to Scribonius Curio, proconsul of Macedonia, B.C. 76. He was praetor at Rome, B.C. 67. At the expiration of his praetorship, he obtained the province of Africa, which he left to canvass for the consulship; but he was obliged to give up his canvass in consequence of being accused of malversation in his province. During this year, B.C. 65, he formed a conspiracy with Cn. Piso and P. Autronius to assassinate the consuls and part of the senate. Suetonius says that Caesar and M. Crassus were engaged in this plot, and that the latter was to be made dictator, and the former master of the horse. He cites as his authorities Tanusius Geminus, the edicts of Bibulus, the orations of the elder Curio, and Aetorius Naso. (See also Cic. in *Catil.* 4.) The plot was frustrated at first by the backwardness of Crassus and Caesar, and a second time by the hastiness of Catiline. Having procured an acquittal on his trial (B.C. 65) for maladministration in Africa by bribing the judges, and, it is said, the prosecutor also, P. Clodius, he was a candidate for the consulship with Cicero for the year B.C. 63. During the contest he was tried with many others for the murders which he had committed during the proscription of Sulla, to whose party Catiline belonged, and especially for that of Marius Gratidianus, uncle of Cicero, but, through

the influence of the consular senators, he was acquitted. According to some, this murder, which was committed many years before, in addition to the imputed seduction of Fabia, Cicero's sister-in-law, laid the foundation for that animosity with which Cicero afterwards pursued Catiline. Yet Cicero says (*Ad Att.* i. 16) that he had some thoughts of defending him on his trial for this seduction.

In the beginning of June, B.C. 64, about a month before the consular election, urged by the ruined state of his fortunes, Catiline held the first meeting of his second conspiracy, eleven men of senatorian rank and four of equestrian being present. Some rumour of these proceedings got abroad, and Catiline lost his election, while the previous preparations of Cicero prevented the execution of a design which Catiline had formed to kill the consul and other senators on the day of election. Notwithstanding this failure Catiline still pushed forward his designs with great vigour. Money and arms were collected, and Manlius, one of Sulla's veterans, only wanted Catiline's orders to take the field with a large body of his comrades, who, after Sulla's victories, had been settled in different parts of Italy. Information of all their proceedings was conveyed to Cicero, and by him communicated to the senate, who, on the 21st October, issued the decree in the usual form, (*Parens operam, &c.*) which gave dictatorial power to the consuls. On the 6th November, another meeting of the conspirators was held, at which arrangements were made for firing the town and massacring the inhabitants, for the bringing up the Tuscian army under Manlius, and for the murder of Cicero, all which was reported the same evening to Cicero. Catiline still kept up the appearance of innocence, and though impeached by L. Paulus under the Plantian law, came down to the senate, which was assembled by Cicero on the 8th November. It was on this occasion that Cicero broke out into the celebrated invective, commencing 'Quousque tandem abutere, Catilina, nostra patientia?' When he had concluded, Catiline, in an humble voice and manner, began to defend himself, but was interrupted by the senate calling out that 'he was an enemy and a traitor to his country.' Catiline abruptly left the senate-house, and set out the same night for the camp of Manlius, with the view of making some decisive movement before the consuls could get an army together to oppose him. The senate immediately declared him and Manlius enemies to the state, and ordered the consuls to raise new troops, of which the command was given to C. Antonius, the colleague of Cicero. Q. Marcus Rex and Q. Metellus Creticus were at this time waiting with their armies outside the gates for the honour of a triumph. It being reported that the slaves were arming in Apulia and Capua, Metellus was despatched into Apulia, and Marcus to Fasula, where Manlius was encamped. A remonstrance, addressed to Marcus by Manlius, setting forth their grievances, was answered by reference to the senate, but it does not appear that any engagement took place. Up to this time, Catiline made little progress, in consequence of his plans being regularly divulged, through the mistress of one of the conspirators, to Cicero, and his designs were consequently thwarted; while, on the other hand, the prospect of the conspiracy being crushed seemed equally distant.

A high reward which had been offered by the senate for information respecting the plot had produced no evidence, and it appears certain that a large proportion of the population (Sallust says the whole of the common people) approved of Catiline's design. But how far they were desirous of change from the hope of plunder, and how far from a well-grounded dissatisfaction with the government of the senatorian oligarchy, it would be a difficult matter to determine. The senate certainly did not appeal to the people for support against a common enemy. An unsuccessful attempt of the remaining conspirators to draw into the plot the ambassadors of the Allobroges, at that time in Rome, and to obtain from them a body of horse, furnished the consul with evidence against the principal conspirators. Lentulus, Gabinius, Statilius, and Cethegus were arrested. Fresh plots were now rumoured to be hatching among the dependents of the conspirators for their rescue; and after a long debate in the senate on the 5th December (*Nonis Decembribus*), in which Caesar argued against, and Cato in favour of the capital punishment of the conspirators, they were condemned to death without the form of a trial, and executed accordingly. Catiline now found himself hemmed in by Metellus Celer on the side of Cisalpine Gaul, and by Antonius, now proconsul, with a sup-

rior force among the Apennines. He made a desperate attack on the troops of Antonius, which were under the command of M. Petreius, was defeated, and fell among the thickest of the enemy, fighting bravely to the last, B.C. 62.

The history of Catiline's conspiracy is chiefly transmitted to us by Cicero and Sallust, and we have only one side of the story. Though there is doubtless great exaggeration in both these writers, and though it seems impossible to penetrate the whole design of Catiline, there is not much difficulty in forming a general opinion of this plot. The civil wars of Marius and Sulla, which terminated in favour of the latter party, led the way to an organized system of murder and plunder, of which few histories present so frightful an example. The partisans of Sulla were enriched by the proscription and robbery of their fellow citizens. This was the school in which Catiline and many of his accomplices were brought up. A body of profligate young men of rank, overwhelmed with debt, whose only pursuit is pleasure, are the readiest elements out of which to form a conspiracy. The conspiracy of Catiline was a conspiracy of an aristocratic faction against the body of which it formed a part; a body that had its own interested views and exclusive objects, but preferred accomplishing them in a more politic and less violent way. If the conspirators had succeeded, they would, as a matter of course, in following up the example of Sulla, have crushed the whole aristocratical party whose views were opposed to their own. The possession of all the influence in the state—the spoliation of their wealthy enemies, would have been the reward of the partisans of Catiline; but it is difficult to conceive that any one useful result to the state would have followed: and, in the absence of better evidence as to the character and abilities of the conspirators, it is impossible to conclude that Rome would have been fortunate enough to find among them a master who possessed the wisdom and moderation of the dictator Cæsar.

CATILLUS. [MARGARITACEA.]

CATKIN, in botany, is a kind of inflorescence which differs from the spike in nothing but its falling off the stem by an articulation, after its temporary office as the support of the organs of reproduction is accomplished. It occurs in the willow, the poplar, the birch, &c., which hence are sometimes called *Amentaceous* plants, amentum being the Latin name of the catkin.

CATMANDOO, the capital of the kingdom of Nepal, in northern Hindustan, is situated in 27° 42' N. lat., and 85° 2' E. long., on the east bank of the river Bishnumutty. Catmandoo is the usual residence of the Ghorka Rajah, by whose predecessor Nepal was conquered about the year 1763. Catmandoo stands upon the high ground that separates the sources of the rivers Gunduck and Cosi, and is at an elevation of 4784 feet above the level of the sea. The town is estimated to contain 5000 houses, and has a population of 20,000 souls; the streets are narrow and dirty, the houses are built of brick, and are three or four stories high; the whole, including the residence of the rajah, are mean in appearance. Catmandoo is an ancient place, and is spoken of in old books under the name of Goongoolpatan.

CATO, i. e. the Wise, was a surname given to MARCUS PORCIUS PRISCUS. This extraordinary man, commonly called Cato Censorius or Cato Major, to distinguish him from his descendant who fell on his sword at Utica, was born in the year 234 B.C. He was descended from a respectable family in Tusculum, and passed his earlier years on a farm in the Sabine country, which he inherited from his father. At the age of seventeen a Roman necessarily became a soldier, and Cato's military career commenced in the very year when Hannibal was laying waste the North of Italy after the battle of the Trebia, 217 B.C. We find him afterwards serving under the command of Fabius, at the capture of Tarentum, in 209; and two years after he distinguished himself at the memorable battle on the banks of the Metaurus, which was fatal to the brother of Hannibal. In private life he maintained the same character for hardness, industry, and sobriety which he had earned in the military profession. Occupying a farm adjoining that which had once belonged to Curius Dentatus, he seemed to take that old Roman for a model, and drew upon him the attention of the neighbouring farmers, not more by the simplicity of his habits than by the plain good sense of the laconic maxims which fell from his lips, and became current in the neighbourhood. His singular reputation obtained him the name of Cato, and at length attracted the observation of a young Patrician, named L. Valerius Flaccus, who, looking

upon him, to use the language of Plutarch, 'as a plant that deserved a better soil,' persuaded him to remove to Rome, and to offer himself for the public magistracies. With this friend, who thus introduced him to the Roman public, he afterwards held the highest posts in the state, the consulship and the censorship. The first of the series of Roman offices was the quaestorship. This he filled in 204 B.C., and was appointed to join the army in Sicily, which Scipio was about to carry across into Africa; but the profuse expenditure of the general offended those notions of strict economy which belonged to the character of Cato. The quaestor returned to Rome, and taking his seat in the senate, to which he was entitled by right of his office, he denounced the conduct of Scipio as fatal to the discipline of the army. Soon after we find him, according to Nepos, acting as quaestor in the island of Sardinia, where he became acquainted with Ennius. It is more probable that the acquaintance with Ennius was formed when Cato was in Sardinia as prætor. The errors of Nepos, or rather of the writer, whose works are ascribed to him, are innumerable. Cato, with all his rustic character, was a friend to literature, and it was he who first brought the Calabrian poet to Rome. After holding the plebeian ædileship and the prætorship, in the latter of which he was the governor of Sardinia, he finally arrived at the consulate, which he filled in 195, the year of Terence's birth, having his friend Valerius for his colleague. At that period of the Roman commonwealth it was usual for the consuls to hold commands at a distance from Rome. Cato was appointed governor of Nearer Spain, where the vigour of his arms and the policy of his counsels added greatly to the Roman influence, and procured him the honour of a triumph in the following year. He had now attained to the summit of military glory, but his zeal was not fatigued. The new consul, Tiberius Sempronius, being despatched on an expedition against the Thracians and the neighbourhood of the Danube, Cato accompanied him as one of his lieutenants.

When Antiochus invaded Greece, we find him again in military employment in the Peloponnese, securing the fidelity of Corinth, Ægium, and Patrae; and in 191, by a bold movement, he dislodged Antiochus from the pass of Thermopylae, and had the chief glory of the victory gained there by M. Acilius Glabrio. In 184, the year in which Plautus died (it is useful to connect the life of Cato with the literature of his country), he was elected censor, and, as was before observed, with Valerius for his colleague. This censorship he made memorable in the annals of Roman history by the strictness with which he executed the important duties. He was now 50 years of age, and he continued for more than 30 years to take a prominent part in public life. But the unflinching determination with which he attacked the crimes and vices of the nobles called up many assailants upon himself. No Roman was ever a party to more public prosecutions, or had to defend himself against more. Even in his 81st year, he had to support himself against an accusation which had no foundation but the malice of his enemies, when he was led to say how cruel it was that, having passed his life with the men of one generation, he should have to defend it against those of another! But these attacks produced no effect upon his courage. When Sergius Galba had disgraced his country by the massacre of the Lusitanians after they had surrendered upon terms, and was brought to public trial at Rome, Cato again subscribed his name as one of the prosecutors, and took an active part in the proceedings. This trial was followed almost immediately by his death, at the age of 85, in the year 149 B.C. Thus as he entered active life soon after the invasion of Italy by Hannibal, so he just lived to see the commencement of the third Punic war, a war indeed into which the Romans were induced to enter chiefly by the urgent advice of Cato himself.

So far we have seen in him the successful soldier and the vigorous statesman. As an orator, an agriculturist, an historian, he was scarcely less celebrated. When yet living on his Sabine farm, he had been in the daily habit of appearing in the petty courts of the neighbourhood as the able advocate of his friends; afterwards at Rome he was one of the most distinguished orators in the forum; and as many as 150 of his orations were preserved and admired for many ages. As a writer on agriculture, he is still known by his work entitled 'De Re Rustica,' which, however, is certainly not in the form in which he wrote it. The language is not sufficiently antiquated for the age in which he lived; and besides this, there is abundant evidence that several parts of the work

are lost, particularly the dedication to his son. The work, as we have it, consists of very brief directions for the management of a farm, and for economical housekeeping, from the buying of an estate to a charm for curing oxen and a receipt for cheese-cakes. It is in this work that he lays down the principle, which excites the just indignation of Plutarch, the duty of selling off old oxen, waggons, and old slaves (§ 2). Of his historical works but a few fragments remain. It was entitled 'Origines,' and, according to the life of Cato, which passes under the name of Cornelius Nepos, the first book treated of the Roman monarchy, the second and third of the origin of the chief cities of Italy, the fourth and fifth of the first and second Punic wars; the sixth and seventh continued the history down to the prætorship of Galba above mentioned. In the latter part of his history he enlarged upon his own achievements without any affectation of modesty. This history was written at the close of his life, so that Livy is guilty of an anachronism in making the tribune L. Valerius quote the 'Origines' against the author at the time when Cato was consul. (Liv. xxxiv. 5.)

Cato was twice married. By his first wife he had a son, Marcus, who married a daughter of L. Æmilius Paulus, the sister of the second Scipio Africanus, and died while prætor during his father's life-time. His second wife was Salonia, by whom he had a son, surnamed from his mother Saloniinus. This son was the grandfather of Cato Uticensis. The character of Cato is boldly drawn by Livy in the 40th chapter of his 39th book. He was indeed, as Livy calls him, a man of iron body and iron soul, *ferret prope corporis animique*. The chronology of the life of Cato is tolerably certain, notwithstanding the errors of Livy, Plutarch, Valerius Maximus, and Cornelius Nepos. See Clinton's *Fasti*. His historical fragments are printed at the end of Coste's *Sallust*; they have been also published by Krause, in his *Fragmenta veterum Historicorum Romanorum*, Berlin, 1826, and separately by Laon, under the title 'Catonianæ,' Gott. 1826. The 'De Re Rustica' is found in Gesner's and in Schneider's collection of Latin works on that subject.

CATO, MARCUS PORCIUS, who was surnamed Uticensis (of Utica) from the place of his death, was the great-grandson of Cato the Censor, and born B.C. 93. He is said to have shown in early youth great powers of mind and firmness of character. When very young he was chosen to fill the office of priest of Apollo, and, that he might the better discharge the duties of his office, he determined to secure the instructions of a preceptor in morality. The character of his mind naturally led him to embrace the philosophy of the Porch, and he became a pupil of Antipater the Stoic. Inflexible decision, severity, and harshness appear to have been the prominent features of his mind; and the great privations and hardships to which he frequently subjected himself, such as abstaining from food, and making long journeys bareheaded and in all weathers, were calculated to strengthen these peculiarities. His half-brother Curius was lost at sea, on which occasion he is said to have relaxed the sternness of his spirit, and he who rarely laughed was then seen to weep. The body was cast ashore by the waves, and was buried by Cato with great honours.

Cato's military career commenced with his serving as a volunteer in the war of Spartacus, in which campaign he is said to have refused the distinctions with which Gallus, his commander, would have rewarded him. He afterwards went as a legionary tribune to Macedonia, and there presented a model of sobriety and courage. The designs of Metellus subsequently induced him to become a candidate for the office of tribune of the people. He was successful in his application, and gained by his conduct the general esteem of the public. Cato took part with Cicero against Catiline, and first gave him the title of *Pater Patriæ* (Father of his Fatherland); the speech which he made on this occasion respecting the punishment of the conspirators is preserved in Sallust (*Catil.* c. 52). He vehemently opposed the union of Pompey, Crassus, and Cæsar, and, though threatened with banishment, he spoke against Cæsar's Agrarian law. Through the influence of Cicerus he was sent to seize Cyprus, in the hope that he would destroy his own influence by failing in the enterprise; and, that he might be kept the longer away from Rome, he was ordered to go to Byzantium to settle the affairs of that town. On his return he was elected prætor, in which office he endeavoured, as far as possible, to put a stop to bribery and corruption. At length,

being unable to bring about a reconciliation between Cæsar and Pompey, he sided with the latter, and on the death of Pompey, went over to Africa. Some dispute arising about the command of the troops in Africa, Cato resigned it to Q. Metellus Scipio, the father-in-law of Pompey; but he afterwards repented of this step, and wished that he had retained the command in compliance with the wishes of the army. Africa soon submitted to Cæsar, and the little that remained to oppose him was contained in the city of Utica. Cato encouraged his countrymen to stand a siege; but the approach of Cæsar altered them into submission. Upon this Cato advised his friends to save themselves by flight, and he even accompanied them to the port. Those who remained in Utica chose Lucius Cæsar to intercede for them with the conqueror, and Cato is said to have composed the speech which he was to make; but he would not allow his own name to be included in the petition. After an evening's meal, and a spirited conversation with some other philosophers, he withdrew to his chamber, and, after embracing his son and friends with unusual affection, he lay down and read a portion of Plato's *Phædon*, on the immortality of the soul. His son and friends in vain entreated him to desist from his resolution to commit suicide. He stabbed himself below the breast and died the same night. The inhabitants of Utica exhibited the utmost sorrow at the death of one whom they regarded as their benefactor and deliverer; nor did the approach of Cæsar prevent them from solemnising his funeral with the greatest pomp. When Cæsar heard of Cato's death, he is said to have exclaimed, 'Cato, I envy thee thy death, since thou hast envied me the glory of saving thy life!' He died, according to some, in the 48th, and according to others in the 59th, year of his age. (Plutarch's *Life of Cato*; Cicero, *de Offic.* i. 31; Sallust, *Jatil.* cc. 52-54; Valer. Maxim. ii. 10. 7; Aul. Gell. iv. 10; *orat. Od.* i. 12. 35, ii. 1. 24; Lucan, i. 125; Virg. *Æn.* vi. 841, viii. 670; Juven. xi. 90.)

CATOPHRAGMUS. [CIRRIPEDA.]

CATOPTRICS. [OPTICS.]

CATOPTROPHIUS. [TOTANUS.]

CATS, JACOB, a very eminent Dutch poet, whose writings were for a long period far more popular than those of any of their authors among his countrymen, was born at Brouwershaven, in Zealand, November 10th, 1577. His mother dying while he was very young, and his father marrying again, he was taken in charge by a maternal uncle, who spared no cost on his education; but his progress in his earlier studies was by no means such as to give earnest of what he would afterwards perform, although he took great delight in reading poetry for his amusement. At Leyden he went through a course of jurisprudence, and made some proficiency in Greek, but never attained to any great acquaintance with Greek literature, a deficiency which, in his more advanced life, he greatly regretted. On quitting Leyden, he proceeded to Orleans, where he took the degree of doctor of laws; and he remained some time in France, both in order to perfect himself in the language and for the purpose of enjoying a tone of society in comparison with which he felt that of his own countrymen to be cold and unpolished. On his return home, he first practised as advocate in Brouwershaven, where his agreeable address and quickness soon obtained for him considerable repute in his profession. Being attacked, however, with an obstinate tertian fever, he was advised to try the effects of travelling and change of air, on which he visited England, but reaped no other advantage from his journey than an acquaintance with the language, and what he derived from the studies he pursued at both Oxford and Cambridge. At length, after having in vain sought relief from all the medical men whom he consulted, he recovered his health by means of a powder given him by an old soldier. He now removed to Middleburg, where he married a lady named Valkenburg, by whom he had five children. It was during this part of his life—the one which he afterwards, amid the toils and dis-

nities of office, acknowledged to have been by far the most enviable portion of it—that he produced his ‘*Emblems*,’ and ‘*Spiegel van den Ouden en Nieuwen Tijd*.’ But the war which broke out in 1621, compelled him to quit Middelburg and go to reside at the Hague. After being made pensionary of Dordrecht, in 1625, he was dispatched on an embassy to England in 1627; when he was knighted by Charles I. About nine years later, he was elevated to the dignity of pensionary of Holland, which he retained till 1631, and in the following year again came over to England on an embassy to Cromwell, although he would fain have excused himself from the honour, and was ultimately obliged to return without having effected any of the objects of his mission. This was the close of his public life; and he was now permitted to enjoy, in his rural retreat at Zorgvliet, near the Hague, that tranquillity and leisure after which he had long sighed. It was here that at an age exceeding threescore and ten by several years, he resumed his literary and poetical pursuits, and composed his ‘*Buitenleven*’ (Country Life), and numerous other productions, constituting the principal bulk of his works. Thus usefully as well as innocently employed, he continued to enjoy life, while he looked forward to death without apprehension, till he expired calmly, September 12th, 1660, shortly before he completed his 83rd year.

Cats’ popularity with his countrymen, by whom he is familiarly yet affectionately styled *Vader Cats*, was derived from more sterling merits than usually accompany more brilliant genius. His works may be regarded as a fund of moral instruction for all ranks and ages, and as a vast store-house of didactic precepts and examples applicable to almost all the varying circumstances of life. His muse never takes any elevated flights; on the contrary, his poetical style, always plain and familiar, occasionally borders on the homely and colloquial, but most of his poems being in the form of dialogue, such a style is not only excusable but appropriate, nor does it ever sink into the mean and vulgar. It is for the most part marked by a naïveté of thought and expression, and by a simplicity, which are becoming and agreeable enough. Like his diction, his versification is easy though rather monotonous, and appears to have flowed from his pen without effort; and he certainly did touch towards refining and improving his native tongue, imparting to it greater freedom and pliancy. He frequently exhibits like wise striking originality and felicity of ideas. But with him manner was only secondary and subsidiary to matter; his aim was not so much to shine as to instruct, and it is in the character of a moral teacher that he is chiefly to be viewed. His lessons are those of practical wisdom and virtue, not lofty speculations too subtle and refined to influence men’s conduct, but instructions applicable to the daily concerns of life. He addressed himself to the many, and there can be no doubt that his works have been largely influential for good, and all the better calculated to attain their end by combining entertainment with moral instruction. Numerous anecdotes and historical illustrations are introduced. At the same time he is not exempt from the charge of prolixity and excess, occasioned by his copiousness. At the present day, both his language and manner have become somewhat antiquated; and accordingly he is now more praised than read.

CATSKILL MOUNTAINS. [APPALACHIAN MOUNTAINS, p. 178.]

CATTARO. [DALMATIA.]

* **CATTEGAT, or KATTEGAT.** [BALTIC.]

CATTI, a people of Old Germany, who lived between the Rhine and the Visurgis (Weser) as far east as the borders of the Hercynian forest. Tacitus (*German.*, 30) describes them as a fierce, hardy, robust race, skilful in their mode of warfare, which partook more of the character of a regular campaign than of that of the predatory incursions of other German tribes. Unlike other German nations, whose chief strength lay in their cavalry, the Catti fought chiefly on foot. The Batavi were a tribe of the Catti, who left their native grounds on account of some domestic differences, and settled in the islands at the mouth of the Rhine. [BATAVI.] The Catti, with the Cherusci, Tencteri, and others, fought against Drusus, who defeated them; but some years after they defeated Varus and destroyed his legions. In the reign of Tiberius, Germanicus, the son of Drusus, attacked the Catti with a large force, overran the country, and made a slaughter of them, sparing neither the women nor the

children. (Tacitus, *Annal.* i. 55.) The Catti however con-

tinued in arms against the Romans for a long time after, and we find them under Vitellius aiding the revolt of Civilis the Batavian chief. They afterwards quarrelled with their neighbours the Hermunduri, by whom they were nearly exterminated. (*Annal.* xiii. 37.)

CATTLE. In its most extensive sense the word cattle denotes all the larger domestic quadrupeds, which are used for draught or food. In the usual acceptation of the word it is confined to the ox or what is called black cattle or horned cattle. But as many varieties are not black, and several have no horns, the name of *neat cattle* is more appropriate. The rearing and feeding of cattle is a very important branch of agricultural industry. Much of the success of a farmer depends on the judicious management of live stock, without which his land cannot be maintained in a proper state of fertility. The breeding and fattening of cattle are generally distinct occupations. It is of the greatest importance to the breeder, as well as to the grazier, to ascertain the qualities of each different breed of cattle; to determine which is best suited to his purpose, and which will bring him the greatest profit.

The domestic bull and cow are probably of Asiatic origin. In those countries where they are now found in a wild state, they are evidently descended from domestic animals which have been let loose, or have strayed from the habitations of man. The *Urus*, which ranged wild in the Hercynian Forest, and was a dangerous enemy to those who encountered him, appears to have differed little from the common bull. If he was an indigenous wild animal, he was perhaps the original stock from which our different European varieties sprung, modified by climate and difference of pasture. This however is denied by naturalists, who consider him a distinct species. [BISON.] The small Hindoo ox with a hump on the chine, and the African Cape ox, which is used for riding as well as for draught, and has no hump, are both more nearly allied to the buffalo. They are very tame, and more intelligent than the generality of our oxen, owing probably to their being more nearly associated with their masters. Of the cattle on the Continent of Europe, one of the principal breeds is the Polish or Ukraine. The oxen of this breed are large and strong, and fatten readily in good pastures. Their flesh is succulent and well tasted; but the cows do not readily allow themselves to be milked, and consequently are not fit for the dairy. The colour is generally a light grey, seldom either black or white. They are docile when worked; but are not considered so hardy and strong as the Hungarian oxen, which resemble them in colour, but are more compact, and have shorter limbs. The horns are large and spreading, which gives them a formidable appearance, and compared with the more improved and carefully bred cattle, they are heavy and coarse. When they are stalled in winter on hay and roots, they bring a considerable profit by fattening very soon. They are driven in herds from the extensive plains in which they are bred, and sold to graziers in the adjoining districts of Germany.

In the plains of Jutland, Holstein, and Schleswig, there is a very fine breed, with small short crooked horns, which appears to be nearly allied to the Friesland and to our own Holderness breed. They are of various colours; but mouse or fawn colour, interspersed with white, are the most common. Red cows of this breed are seldom seen. They are good milkers in moderate pastures, and the oxen fatten readily when grazed or stall-fed at a proper age. They are fine in the horn and bone, and wide in the loins; but they are not considered so hardy and strong for labour as the preceding breed. If prejudice did not make the breeders select the calves with large bone and coarse features to rear as bulls, in preference to those which resemble the cows, this breed would in every respect equal our best short-horns. The cows are frequently fattened while still in milk, and are fit for the butcher by the time they are dry; the same system is followed by the great milkmen in the neighbourhood of London, with their large Holderness cows. This breed is much esteemed in all the northern parts of Europe. The Friesland, Oldenburg, Danzig, and Tilsit cattle, are mostly varieties of this short-horned breed.

Towards the Alps the cattle have a different character; they are strong and active, and can range wider in search of pasture. The largest and finest breed is the Swiss, especially the Freyburg race, which is found in the rich pastures between the mountains in the neighbourhood of Greyerz (Grüyères), a place well known for its excellent cheese

which is consumed all over Europe. The cows, which are here the principal object of attention, are large and wide in the flanks, and strong in the horn—we should rank them in England among the middle breeds—short and strong in the bone, with a prominence at the root of the tail, which, according to our notions, would be considered a great blemish. They give abundance of rich milk when ranging in their native Alps, or when stalled and fed with clover or lucern in the stables. The oxen fatten well, but are rather heavy and slow. When fed off they fatten well; and although fat meat is not much prized there, some carcasses may be seen slaughtered in Bern and Freyburg which are equal to those in the best English markets.

There is a smaller, but very active mountain breed cattle in the Jura, which does well on scanty food. The cows are small and slight, generally of a light red colour. The oxen are very active and strong for their size. They draw invariably by the horns. They are not considered so profitable for stall feeding as the larger, but they are excellent for the small cottagers on the borders of the mountains, and find their sustenance among the woods and rocks, where they climb like goats.

The Norman breed gives the character to all the cattle usually met with in the northern part of France, except near the Rhine. They are mostly of a light red colour, sometimes spotted with white. Their horns are short, and stand well out from the forehead, turning up with a black tip; the legs fine and slender; the neck high, and the thighs thin. The cows are good milkers, and the milk is rich. They are in general extremely lean, which is owing in a great measure to the scanty food they gather by the sides of roads, and along the grass balks which divide the fields. In Normandy itself they have good pastures, and the cattle are larger and look better. The Alderney and Jersey breeds, which from the extreme richness of their milk are much prized in gentlemen's dairies in England, are smaller varieties of the Norman, with shorter horns, more turned in, and a still more deer-like form.

The Italian breeds are not very remarkable, except from the immense length of the horns of some of them. No great pains are taken to improve them, except in some parts of the north of Italy, where the Parmesan cheese is manufactured: there they resemble the Swiss breed, and are probably only varieties of the same stock.

The different British and Irish breeds have been generally distinguished from each other by the length of the horn. The long horned breed is supposed by many to be indigenous. Others consider the middle horned as the old breed. The former was chiefly found in a district of Yorkshire called Craven, and was greatly improved by the skill of Robert Bakewell, of Dishley Farm, in Leicestershire, and hence they are called the Dishley breed. The distinguishing character of this breed are long horns growing downwards from the side of the head and ending in straight points parallel to the jaw. In order to give an adequate idea of the qualities of this improved breed, we must consider what breeders and graziers call the fine points of an ox. These are certain forms and appearances, which are either anatomically connected with a perfect conformation of the body, and especially of the organs of respiration and of digestion, or which are constantly associated with the peculiar qualities of certain breeds, so as to be proofs of their purity. Of the first kind are a wide chest, well formed barrel, strong and straight spine, hip bones well separated, and length of quarter, all which can be proved to be essential to the perfect functions of the body. Small and short bones in the legs give firmness without unnecessary weight. A thick skin well covered with hair insures proper warmth, and its soft loose feel indicates a good coat of cellular substance underneath, which will readily be filled with deposited fat. All these are indispensable points in an ox which is to be profitably fattened, and whatever be the breed, they will always indicate superiority. Other points, such as colour, form of the horns, shape of the jaw, and setting on of the tail, with other particulars, are only essential in so far as experience has observed them in the best breeds, and as they are indications of pure blood. The eye is of great importance; it should be lively and mild, indicating a healthy circulation, with a gentle and almost indolent temper. An animal that is not easily disturbed will fatten rapidly, while one that is restless and impatient will never acquire flesh. Amongst the ancients, a deep dawlapp was considered as a great beauty in an ox. In some of our best breeds there is

scarcely any. The rump of the Freyburg cows, as we observed before, rises high towards the tail; while a straight back from the neck to the tail is indispensable in a well-bred British ox.

Having established a breed which has many superior qualities, attention is paid to maintain its purity; and to those who cannot ascertain the parentage, certain marks are satisfactory proof of purity of blood. The new Leicester long-horn oxen were noted for the smallness of the bone and their aptitude to fatten. Their flesh was fine-grained, the fat being well intermixed in the muscles. At the time when Bakewell died, about 1793, no other breed could be brought into competition with his improved long-horns. But whether his successors have not paid the same attention to keep up the qualities of the breed, or it has degenerated in comparison, they have since lost much of their reputation, and the short-horned breed has now the superiority. Good long-horned cattle are, however, occasionally seen in the midland counties. One defect of the breed was, that the cows gave but little milk, and this may be the reason for now preferring the short-horns. The Teeswater or Holderness breed of cattle was produced by the importation of cows from Holstein or Holland, and careful breeding and crossing. They now much excel the original stock. The principal improver of the Teeswater breed was Mr. Charles Collins. By his care a breed has been produced which is unrivalled for the dairy, and for fattening readily. Almost every good breed now in existence traces its pedigree to his bulls, especially one of the first he used, called *Hubback*. The famous ox exhibited thirty years ago, under the name of the Durham ox, was of this breed. By careful crossing with a Galloway cow, an improved breed was produced, which was in such repute that at a sale of Mr. Collins's stock of short-horns, October 11, 1810, a famous bull, called *Cornet*, sold for 1000 guineas, and 48 lots of bulls, cows, and calves realized 7115*l.* 17*s.* (*Library of Useful Knowledge*, 'Cattle,' p. 233.) The short-horn cattle are mostly light coloured, some quite white, but most are speckled with red and white, without any large distinct spots. The horns are very short. In the cow, the points turn inwards towards each other. Some of the finest bulls have merely a tip of a horn standing out from each side of the forehead. In the carcass they have every point which we have before enumerated as essential to perfection.

Besides the two breeds above mentioned, there are several of great repute in particular districts, which almost dispute the superiority with the short-horns. Of these the Devonshire breed is the handsomest. The colour of this breed is invariably red, with a very fine head, small bone, and glossy side. The oxen, although not so heavy as some, are the best for the plough on light lands: they walk nearly as fast as horses, and will work almost as well in pairs. The cows are good milkers, any deficiency in quantity being made up by the richness of the cream. The oxen fatten readily, and their flesh is of the best quality.

The Sussex breed is only distinguished from the Devon by being rather stronger, and not so fine in the head and horn.

The Herefordshire breed is larger and heavier than either of the preceding, the horns longer and more turned outwards; the colour is red, but the belly and the face are generally white, and there is often a white stripe along the back. This breed has many excellent qualities, and fattens well; but the cows are of little use for the dairy, from the small quantity of milk they yield. The Herefordshire oxen are best suited to the rich pastures of their native county, where they grow to a great size and increase fast. These are the principal English breeds. Of the Welsh breeds, the Glamorganshire cows are in good repute for the dairy: they are of a dark brown colour with a white stripe along the back, long white horns pointing rather forwards and upwards; the tail is set on rather high above the back, which is thought a defect, but in this they are much excused by the Freyburg cows mentioned above, which have great merit notwithstanding. The other Welsh breeds are distinguished chiefly by their hardy constitutions, which they owe to their having been bred in mountainous districts. Great droves of them come to all the English fairs; their low price and small expense of keep render them an object worthy the attention of cottagers and small farmers; they are best calculated to turn in rough heaths and commons.

The principal indigenous Scotch breeds are the West Highland, the Galloway, the Angus, and the Shetland.

There is a doubt whether the Ayrshire should be classed amongst the pure Scotch cattle. Their great resemblance to the short-horn in all but the size leads one to suppose that they are a cross of a smaller breed by a short-horn bull, but they have very good qualities, and are excellent for the dairy or for stalling.

A great many cattle are bred in the various islands which lie on the western coast of Scotland. They are mostly of a small black breed, called Kyloes. They are very hardy, and when brought into good pasture, fatten rapidly and produce the finest and best flavoured beef. They are found in the greatest perfection in the Isle of Skye, and are sent annually in large droves from their native islands, and dispersed through Scotland and England. They are particularly in request in Norfolk, Suffolk, and Essex, where they are wintered on turnips, and sent to Smithfield in the spring and summer following. If they do not produce so great a weight of beef as many other breeds, they always bring the highest price in the market, and require but a very short time to get fat. The Galloway is a peculiar breed, which has many good qualities: it has no horns; the body is compact, and the legs short; and few breeds can vie with the Galloway oxen and heifers in aptitude to fatten. There is a peculiar roundness in all the parts of the body, which makes the animal look well in flesh, even when he is lean. The skin is loose, and the hair soft and silky to the touch. They are mostly black, but some are of a dun colour, which shows a connection between this breed and the polled Suffolk. It is only the colour which distinguishes them. Many of the Galloway heifers are spayed, and get very fat at an early age. The Galloway cows are not very good milkers, in which respect they differ from the Suffolk, but their milk is very rich.

The Angus doddie is also a polled breed, and has been long in repute. It is probably a variety of the Galloway, to which it bears a strong resemblance, but it has been found in Angus from time immemorial.

The Shetland cattle are very diminutive and coarsely shaped, but their flesh is reckoned well flavoured. They are seldom driven into England or the South of Scotland, because when fat they attain but a very small weight. The breed is, however, worth the notice of experimental agriculturists.

The Aberdeenshire and Fifeshire breeds are horned, and have been produced by various crosses with short-horns and other English breeds. All the Scotch breeds have been greatly improved by the premiums given by the Highland Society for the encouragement of breeding.

Of Irish cattle, the small Kerry cow seems to be purely native. It is a useful breed for cottagers, requiring but moderate keep and care, and giving a considerable quantity of milk, in proportion to the size of the animal and the food it requires.

The best Irish cattle are produced by crosses with the improved Leicester long-horns, and in the rich pastures of the south many fine animals were reared and slaughtered for the use of the navy during the war.

These are the principal breeds of cattle in the United Kingdom. By selecting those which are best suited to each situation and pasture, the industrious farmer may add considerably to his profits, and at the same time enrich his land with the manure. In purchasing cattle it is very necessary that the age should be readily ascertained: the surest mode of doing this is by examining the teeth. A calf has usually two front teeth when he is dropped, or they will appear a day or two after his birth; in a fortnight he will have four, in three weeks six, and at the end of a month eight. After this, these milk-teeth, as they are called, gradually wear and fall out, and are replaced by the second and permanent teeth. At two years old the two middle teeth are replaced; the next year there will be four new teeth in all; at four years there are six permanent teeth, and at five the whole eight are replaced. The milk-teeth do not always fall out, but are sometimes only pushed back by the second set: and in this case they should be removed with an instrument, as they impede mastication and irritate the mouth. After six years old the edges of the teeth begin to wear flat, and as they wear off the root of the tooth is pushed up in the socket, and the width of the teeth is diminished, leaving cavities between them: this begins in the middle teeth, and extends gradually to the corners. At ten years old the four middle teeth are considerably diminished, and the mark worn out of them.

After fifteen years of age few cows can keep themselves in condition by pasturing; but they may continue to give milk, or be fattened by stalling and giving them ground food. Horned cattle have rings at the root of the horns, by which the age may also be known. The first ring appears at three years of age, and a new one is formed between it and the skull every year after. But this mode of ascertaining the age is not so sure as by the teeth, deception being much easier by filing off the rings.

In order to learn by experience what breed of cattle is most profitable, it is very advantageous to weigh them occasionally and note their increase. For this purpose several simple and ingenious weighing machines have been invented.

1. For want of better, a strong kind of steel-yard may be made of a young fir tree, about twenty feet long, suspended from a strong beam by a hook fixed about a foot from the thickest end, to which is attached another hook, from which descend strong flat hempen bands, forming two loops joined together by iron rings. These are put under the belly and chest of an ox; and a weight hung at the smaller end of the pole, just sufficient to lift him off his legs, readily gives his live weight. Experience has shown the proportion between the saleable quarters and the offal, in different states of fatness; and tables have been constructed by which the net weight is found by mere inspection. Multiplying the live weight by 0.605, gives a near approximation to the neat dead weight in an ox moderately fat and of a good breed. When an ox is fat, his weight may be very nearly guessed by measuring his girth immediately behind the fore legs, and the length from the tip of the shoulder to the perpendicular line which touches the hinder parts, or to a wall against which the animal is backed. The square of the girth in inches and decimals is multiplied by the length, and the product multiplied by the decimal .238. This gives the weight of the four quarters in stones of 14 lbs. This rule is founded on the supposition, that there is a certain proportion between the net weight of the quarters and that of a cylinder the circumference of which is the girth, and the axis the length taken as above. The proportion has been ascertained by observation and repeated comparison. The measurement will at all events indicate the proportional increase during the period of fattening.

Cattle are not subject to many diseases, if they have plenty of food and good water, and are kept clean. Air is essential to them, and although cows will give more milk, and oxen will fatten better when kept in warm stalls in winter, they are both less subject to diseases when they are kept in open yards, with merely a shelter from the snow and rain. Epizootic diseases, which sometimes ravage whole districts, are less known in England than in most countries. For the peculiar diseases of cattle see Ox and Cow.

The most economical mode of feeding cattle is evidently by allowing them to seek their food on commons and uncultivated pastures; but it is only in particular situations that it is the most advantageous. Cattle fed on commons add little to the stock of manure, except when they are kept in the yards or stalls in winter: even then their dung is of little value, if they are merely kept alive on straw or coarse hay, as is generally the case where the stock is kept on commons or mountains in summer. When they feed in enclosed and rich pastures, their dung falling in heaps on the grass does more harm than good. The urine fertilizes the soil in wet weather when it is diluted; but in dry weather it only burns up the grass. If we calculate what would be the amount of dung collected if the cattle were kept in yards or stables, and fed with food cut for them and brought there, and also the loss of grass by treading on the pastures, we shall have no doubt whether the additional labour of cutting the grass and bringing it home daily is not amply repaid by the saving. But if we also take into the account the variety of artificial grasses, pulse, and roots which may be grown with advantage on land unfit for permanent grass, and the quantity of arable land which may thus be kept in the highest state of cultivation, we shall be convinced that the practice of those countries where the cattle are constantly kept at home is well worthy of imitation. It may be of use to the health of the animals to be

* If g be the girth and l the length taken as above, a the area of a circle whose circumference is unity, then $l g^2 a = \pi$ cylinder; and if the proportion of this cylinder has been found by repeated trials to be to the weight of the carcass in stones of 14 lb. as $b:1$, then $l g^2 \times \frac{\pi}{b}$ is the net weight. In this case

a has been found = 0.238. $\therefore l g^2 \times 0.238$ is the weight.

allowed to take a few hours' air and exercise in a pasture near the stable: but there is no advantage in their having any grass crop there: on the contrary, the barer of grass the surface is, the better. They will relish their food better when they are taken in after a few hours' fasting. A bite of fresh short grass might, on the contrary, give them a dislike to their staler food. When cut grass is given to cattle in the stalls, it is best to let it lie in a heap for at least twelve hours before it is given to them. It heats slightly, and the peculiar odour of some of the plants, which oxen and cows are not fond of, being mixed with that of the more fragrant, the whole is eaten without waste. Experience has shown that many plants which cattle refuse in the field, where they have a choice, have nutritious qualities when eaten mixed with others in the form of hay. There are few deleterious plants in good grass land or water meadows, and these are readily distinguished and weeded out. The quantity and quality of the dung of cattle stalled and well fed is so remarkable, that its value makes a considerable deduction from that of the food given; especially of green food, such as clover, lucern, tares, and every kind of leguminous plant: we shall not be far wrong, if we set it at one-fourth. This supposes a sufficient quantity of straw for litter, and an economical collection of the liquid parts in proper reservoirs or tanks. In order to make the feeding of cattle advantageous, the buildings must be conveniently placed with respect to the fields from which the food is to be brought. Moveable sheds with temporary yards, which can be erected in different parts of a large farm, according as different fields are in grass or roots, are a great saving of carriage, both in the bringing the food to the cattle and carrying the dung on the land. A clay bottom should be selected, in a dry and rather high spot, if possible. But if permanent buildings for cattle, constructed of rough materials and thatched with straw, were erected in the centre of about forty acres of arable land, in different parts of a large farm, it would probably be a great saving in the end.

Good water is most essential to the health of cattle, and that which has been some time exposed to the air seems the best for them. When they are fatted in stalls on dry food, they should always have a trough of water within reach. A piece of rock-salt to lick, or some salt given with their food, is highly conducive to their health, and will restore their appetite when it begins to flag. Rubbing the hide with a wisp of straw or a strong brush, as is done to horses, may appear a useless labour, but it is well known that there is no better substitute for that exercise which is essential to health. Where labour is not regarded, as is always the case when the owner of the cattle attends upon them himself, the curry-comb and the brush are in regular use, and the advantage is not denied.

In those countries where the farmer is allowed to distil a spirit from his grain, it is a great advantage to an agricultural establishment to have a distillery attached to it, especially in a remote situation; and not only is the fattening of cattle on the refuse of the distillation a source of profit, but the manure extends fertility around. The produce in spirits and in cattle is easily transported to a great distance, and almost the whole of what is produced by the land turns to it in the shape of manure. The same may be said of the manufactory of sugar from beet root, which has been lately so much extended in the north of France.

It can never be too much impressed upon the minds of agriculturists, that without dung there is no corn; without cattle there is no dung. Every means should therefore be used to encourage the breeding and feeding of cattle, and none can be more effectual than to show that the profits of a farm are always proportioned to the quantity of cattle kept, and the abundance of the food provided for them.

CATTYWAR, or KATTYWAR, a district occupying a portion of the interior of the Gujerat peninsula, bounded on the N. by Jhallawar, on the E. by Goelwara, on the S. by Babreecawar, and on the W. by Sorot. The surface towards the N. is irregular, and in the S. is jungly. The soil is variable, but sand prevails on the plains, where it is mixed with reddish-coloured rock, of which the hills are mainly composed. These hills are deficient in trees. The more usual kinds of produce are wheat and a few coarser grains. Many horses are reared, the breed being considered among the best in India. The inhabitants, who are not numerous, are known by the name of Catties. Female infanticide is very common in the country; among the higher classes indeed it is nearly universal, notwithstanding the provisions of a treaty concluded with them by the British

in 1807, which stipulated for the abolition of the custom. Their wives are consequently often procured from neighbouring districts. The Catties are allowed to marry any number of wives, but few persons take more than two. The men are an athletic race, and such of the women as are allowed to live, grow up with a considerable share of personal beauty. The Catties are worshippers of the sun. The men are robbers by profession, and attach no idea of criminality to thieving.

The country is divided among numerous tributary chiefs and princes, each exercising independent power within the limits of his own division. Some of these chiefs are under the direct authority of the British, but the greater number are subject to the Guicowar, although these too are placed under the control and management of the Company's officers, by whom the tribute is collected and accounted for to the Guicowar. This arrangement has been found necessary in order to preserve peace in the country. The interference of the British extends sometimes to criminal as well as financial matters. The commissioner of Gujerat visits Cattywar twice in the year, and aided by the Company's political agent and three or four native chiefs as assessors, presides at the trial of persons charged with the commission of capital offences, such as robbery and murder, in the territories of petty states, the chiefs of which are too weak to bring them to punishment. All the rights which the British possess in Cattywar have been acquired from the Pershwa and the Guicowar; from the former by conquest, from the latter by mutual arrangement. Those rights have been considered as limited to the collection of tribute and the preservation of peace; in other respects the Cattywar chieftains have been left to the uncontrolled exercise of all the functions of government within their own immediate territories. Some of the principalities are of considerable extent, but others are of petty dimensions, and one chief is named—the Rana of Purchree,—whose tribute amounts to only 21 rupees per annum. In 1820 there were 37 chiefs directly tributary to the British government.

(Report of Committee of House of Commons in 1832 on the Affairs of India—political division.)

CATULLUS, CAIUS VALERIUS, sometimes, but erroneously, called **QUINTUS VALERIUS CATULLUS**, was born at Verona, B.C. 87, about 17 years before Virgil and 22 before Horace. His father Valerius was of a respectable municipal family in that city, and lived in habits of intimacy with C. Julius Caesar, who appears, when his affairs led him to visit or pass through Cisalpine Gaul, to have taken up his abode at the house of Valerius. Catullus left his paternal roof at an early age for Rome, where he plunged into dissipation and extravagance, mortgaged his estate, and fell into great poverty. His pecuniary misfortunes do not seem to have broken his spirit or abated his good humour. He laughs off his mortgage with a pun, and jokes on his poverty with the utmost indifference. However, to improve his fortune he, together with his brother, accompanied the prætor Memmius (the same to whom Lucretius dedicated his immortal poem) to Bithynia. This expedition, as respects the object our poet had in view, was completely unsuccessful. He returned as poor as he went, and on his voyage home had the additional misfortune to lose his brother, to whom he was affectionately attached, and who died on the coast of Troy. The death of his brother he deploras on more than one occasion in his works with great pathos, and in a style of natural and genuine feeling. The voyage from Bithynia was performed by sea in a small open pinnace, called a phaselus, an undertaking which strongly shows the poet's courage and perseverance. A voyage of that length, from its commencement in the Euxine to its termination on the shores of the lake Benacus, in so fragile a bark, satisfactorily proves that Catullus was not deficient in at least one Roman virtue,—a contempt of danger. He concluded this arduous enterprise by ascending the Po, and finally by the Minicius reached the promontory of Sirmio on Lake Benacus. On this promontory, where he appears to have possessed some property, he dedicated his little bark to Castor and Pollux in some verses which have been much admired. From the time of his return from Bithynia he continued to reside chiefly at Rome, pursuing his pleasures, though living, as we collect from his writings, in poverty. From the same source we derive the information that he possessed estates both in the Saline country and at Sirmio, probably of little value.

His chief or only patron was Manlius Torquatus, on

whose marriage with Julia he wrote his 'Carmon Nuptiale.' Notwithstanding his poverty he lived in intimacy with all the men of talent of his day, among whom were Cicero, Cornelius Nepos, Licinius Calvus the orator, Asinius Pollio, Varus, Cornificius, Caelius of Verona, Hortatius, Caelius, and others. Cicero is supposed by some to have pleaded a cause for him; good critics however deny or doubt the fact. Judging from his writings and the freedom with which he indulges in satire, without regard to the rank, power, or wealth of the object of it, we may fairly pronounce that Catullus possessed a lofty, independent spirit. His boldest flight was against Julius Cæsar, even in the plenitude of his power. He lashed his shameless extravagance and his odious partiality for Mamurra with unsparing severity. For this however he afterwards apologised; and the generous conqueror invited the poet to his table on the same day, and still continued his intercourse with his father Valerius.

Of all the poet's favourites, Clodia, who appears under the feigned name of Lesbia, seems to have enjoyed the greatest share of his affection and of the effusions of his muse. His lines on the death of Lesbia's sparrow, perhaps as well known and as often quoted or alluded to as any verses he ever wrote. In his day Catullus bore the character of a learned person, and the epithet 'doctus' is frequently applied to his name in the various testimonials which have reached us of his fame and merits. This he perhaps obtained from his knowledge of the Greek language, and from the translations he made of some of the odes of Sappho and the poems of Callimachus.

A considerable part of the writings of Catullus is supposed to be lost. He died, according to some, at the age of 10 or thereabouts; according to others he attained the advanced age of 71. The latter opinion is combated at great length, and very successfully, by Bayle in his 'Historical and Critical Dictionary.' The concurrent testimony of all the men of wit and learning of his own and after times establish his character as a man of first-rate talents and a true poet. He possessed a brilliant imagination, and clothed his thoughts in the best language. His style is easy and unaffected; he is always free from conceit or bombast; his lines are full of sweetness and harmony. In his playful moods he has many touches of humour, and is always entertaining and agreeable. When pathetic, his feelings are natural and unstrained. Many of his thoughts have been borrowed by subsequent writers. He fell into the vice of his age, and several of his pieces are degraded by the most obscene ideas couched in the most revolting expressions. The only palliation for this offence that can be offered is the manners of the times, when the grossest violations of propriety were overlooked, if not encouraged, by those whose power, wealth, and influence enabled them to set the fashion.

His longest and most beautiful poem is the 'Epithalamium of Peleus and Thetis.' It has been objected to this piece that the author, immediately after its commencement, digresses into an episode longer than all the rest of the poem, being a narrative of the desertion of Ariadne by Theseus on the shores of Naxos, and having no reference in or connexion with the main story, into which it is introduced as a decoration of the embroidery on the garment of Thetis. To this criticism, which applies to the plan and not to the execution of the poem, it may be observed, that what editors and commentators have thought fit to call the 'Epithalamium of Peleus and Thetis' is possibly only part of a longer and unfinished work, intended by the author to bear a different designation, or it is only the fragment of the entire work which has come down to us. However that may be, the sufferings of Ariadne, and her desertion of her father's house, form a fine contrast with the chaste loves and the happy marriage of the parents of Achilles, and her story may have been selected by the poet with a view to produce that effect.

The poems of Catullus are said to have been unknown to the moderns till the beginning of the 15th century, and that it was only about A.D. 1425 that a copy, found in a library, was first sent to the native city of the author. The following are the most esteemed editions of Catullus:—Volanus, Lond. 1681, and Tr. 1691; Vulpius, Patav. 1737; the 'Verborum of Grævius with Tibullus and Propertius, Tr. 1680; Mattæi's in 1715; in the 'Corpus Poetarum,' Lond. 1713; and Doering, Leipzig, 1786 and 1792.

(Catullus, Suetonius, Vulpius, Bayle, and the different commentators and editors of Catullus.)

CAUBUL, or CABUL. [AFGHANISTAN, p. 169; BELUCISTAN, p. 198.]

CAUCASUS (*Καυκάσιος*) is an extensive mountain system between the Black and Caspian Seas. The general direction of the range is from W. N. W. to E. S. E. It begins on the shores of the Black Sea, or at a short distance from them S. of the small town Anapa, at about 44° 40' N. lat., and 37° 10' E. long.; and terminates on the shores of the Caspian Sea with the peninsula of Abcheron or Abcheran, at 40° 30' N. lat., and 50° 20' E. long.

In length the Caucasus is not inferior to the Alps, the length being hardly less than 700 miles. But the width is considerably less, measuring, where widest, only 120 miles; and where narrowest, hardly more than 60 or 70. If their average width is taken at 80 miles, these mountains cover 56,000 square miles, or nearly the surface of England and Wales taken together.

The Caucasus, in some summits, rises to a greater height than the Alps. The highest ridges are in the two most E. thirds of the whole system. The highest summit, Elbrooz or Elborus, is N. of 43° N. lat., and W. of 43° E. long.; its S. E. side fills the angle formed by this parallel and meridian. This high rocky mass rises to 16,500 feet above the sea, and stands quite isolated, being surrounded by low and marshy ground. The continuous mountain-chain is to the S. of this mass. That portion of the range which extends W. of Mount Elbrooz to the shores of the Black Sea, and afterwards parallel to them, at a distance of about 20 or 30 miles, does not rise to a great elevation; no portion of it is covered with snow all the year round, and Remeggs thinks that it nowhere attains half the elevation of Elbrooz.

That portion of the range which is E. of Elbrooz appears to contain numerous summits and ridges, which rise above the snow line. Kazbeck, between 42° and 43° N. lat., and W. of 45° E. long., attains about 14,400 feet; and further E. occur other high summits, as Tersh and Shah Dagh (King's Mountain), which latter is estimated to rise to between 12,000 and 13,000 feet. There occur other summits nearer the Caspian Sea, which are always covered with snow, but they do not continue far E., and on the peninsula of Abcheron the chain has only the appearance of moderate hills.

The offsets of the Caucasus approach near to the Black Sea, and often advance close to its shores between its commencement at Anapa and the mouth of the Ingour or Inguri, a distance of about 250 miles. Within these limits the shores of the Black Sea are high, bold, and rocky, except at a few points. On the Caspian side the mountains seldom approach the shores. The most N. offset, on this side, occurs on the S. bank of the Koisso, where it approaches within six miles of the Caspian shore. Farther S. the mountains do not approach the Caspian nearer than about 30 miles, but the rock on which Derbent is built, which forms the extremity of another offset, is less than two miles from the Caspian. Another plain follows, which however only extends from 10 to 15 miles inland, and terminates about 12 miles N. of 41° N. lat. The remainder, including the peninsula of Abcheron, is rather high, and the country is hilly.

The Caucasus is entirely unconnected with any of the great mountain-systems of Europe or Asia. To the S. indeed, a range of hills dividing the sources of the Faz or Rioni (Phasis of the ancients), from the basin of the Koor (Cyrus of the ancients), and running along the banks of the latter to its source, (near 41° N. lat., and 43° E. long.) unites it to the chains at the sources of the Euphrates and the table-land of Armenia; but these hills are of small elevation. The plain which is traversed by this range of hills, and through which the Koor runs, slopes gradually to the Caspian. The plain, which extends along the N. side of the Caucasus, hardly contains an elevation that deserves the name of a hill; between the innermost corner of the sea of Azof and the Gulf of Kogima, in the Caspian, it sinks so low that it probably nowhere rises 120 feet above the Black Sea. [CASPIAN SEA.] The offsets towards the N. plain are by far the most numerous, and sometimes extend to 100 miles, but here, as well as to the S., the mountains terminate so abruptly, that even many of the summits, which attain no great elevation, are nearly inaccessible.

The snow line in the latitude of Mount Caucasus varies from 10,000 to 11,000 feet above the sea. One third of Elbrooz is consequently always covered with ice and snow, and a considerable portion of some other summits and ridges. Here, as in the Alps, glaciers are common, and the whole scenery of both mountain-systems has a strong

resemblance, except that the Alps have the great advantage of extensive mountain-lakes, in which the Caucasus, so far as is known, is deficient. In the Caucasus the argali (*Ovis Ammon*) is found, which was long considered peculiar to the table-land of Central Asia and the mountains of Siberia. This mountain-range is also the native country of the common and gold-pheasants. In mineral riches Caucasus is probably superior to the Alps. Traces of gold and copper are common, but hitherto these metals have not been worked, except that a small quantity of gold is washed from the sand of some rivers. Iron abounds in many places, and is worked by the natives in a rude way.

There are no active volcanoes in the Caucasus, but traces of volcanic agency occur. Earthquakes also happen sometimes. Naphtha or petroleum occurs in no part of the globe in such abundance as on the peninsula of Abcheron [BAKU]; but it is not limited to this part of the Caucasus: it occurs in several places on its southern side, and on the N., on the island of Taman, formed by the two branches of the Koorban. The mud volcanoes of the Caucasus seem to be connected with the naphtha, for they occur only in the neighbourhood of it, especially on the island of Taman, and between Baku and Nawagi, where they are conical hills of earth, without any signs of vegetation on them. From a small crater on their summit issues the thick mud, with which a quantity of naphtha is mixed. Sometimes, as in 1828, these eruptions are attended with flames, and followed by a gushing out of columns of water. On the N. side of the Caucasus there is a great number of hot, warm, and sulphuric waters, especially W. of Elbrooz. Salt lakes abound on the peninsula of Abcheron.

The intercourse between the countries S. & N. of the Caucasus is carried on by two roads. The most E. runs along the shores of the Caspian Sea, sometimes close to, and sometimes traversing the interior of the plains, which lie between the sea and the E. extremity of the mountains. This road unites Baku with Derbent, and the latter town with Kizlar, on the Terek. Though this road does not pass over high mountain-ridges, it is not much frequented, a circumstance which may be attributed to the difficulty of crossing the numerous rivers, which, in spring and summer, after the melting of the snow, cover a considerable part of the plains with water. These inundations also make the country, for the greatest part of the year, very unhealthy.

The most frequented road is that which traverses the Caucasus nearly in its centre, beginning on the S. at Tiflis, on the banks of the Koor, and terminating on the Terek, at the town of Mozdok. Leaving Tiflis the road runs along the Koor, through a plain: it then ascends the valley of the small river Arakui, or Aragbor, which grows narrower as the road advances N. Near its upper extremity is the small fortress of Passanaur, erected for the protection of travellers against the warlike inhabitants of the mountains. Between this fortress and another, Kasibeg, lies the highest part of the pass, which is more than 8000 feet above the sea; and on each side of it mountains rise several thousand feet higher, the summit of Mount Kazbeck being at a short distance from it, to the W. In other places the road runs on the edge of an abyss, which descends as far under it as the mountains rise above it. This pass preserves the same character as far as the fortress of Dariel (from which it has received the name of the Pass of Dariel), and even to that of Wladikawkas, where the valley of the Terek may be considered to begin. The part farther S. is hardly more than a mere ravine. The difficulties encountered on this road by the traveller are often increased by the fall of avalanches, or the sudden swelling of the torrents, which descend from the high mountains.

Both these roads were known to the ancients. That which passes the town of Derbent was called Porta Albanica, from Albania, the name of the country watered by the lower course of the Koor. It was sometimes also called Caspian Pyle, but improperly, that name belonging to another road, by which Alexander the Great descended from the table-land of Persia to the low southern shores of the Caspian Sea. The Pass of Dariel was called by the ancients Porta Caucasus.

There is probably no country on the globe, of so small an extent, which contains such a number of different nations, as the valleys of the Caucasus. The natives speak at least seven different languages; but the dialects are nearly innumerable. Strabo states that, in his time, at least seventy languages were spoken on the Caucasus. Some of these languages are thought somewhat to resemble the Persian, others

the language of the Turks, and others that of the Finlanders. That of the Ossetes, or, as they call themselves, of the Iron, contains a great number of German words. The most numerous nations inhabiting the mountains are the Awchases or Abasians, who, with their numerous tribes, are in possession of the S. declivity of the range, between the Black Sea and Mount Elbrooz; the northern side of this range, with its numerous valleys, is occupied by the Circassians. The centre of the range, on both sides of the pass of Dariel, is in possession of the Ossetes or Iron. The Lesghians, or Lesghes, the most numerous and most powerful of the Caucasian mountaineers, occupy the greatest portion of the range E. of the pass of Dariel, and approach the peninsula of Abcheron. They are a warlike people, and the terror of all their neighbours. The extensive mountain tract, bordering on the N. of Mount Tersh, is inhabited by the numerous tribes of the Kisti or Misheghes. In the plain S. of the Caucasus, on the banks of the Koor and Phasis, live the Mingrelians and Georgians. Though all these nations differ in their language, their physical conformation shows that they belong to the same race; and as this race in no other country exhibits such perfection of form, the whole race has obtained the name of the Caucasian race.

Besides these aboriginal tribes, many others, of foreign origin, are met with in the valleys of the range. The most numerous are those of the Turkish race, especially the Tatars. When the different states, which had been founded by the descendants of Djengis-khan, on the countries N. of the Caucasus, were destroyed by the Russians, many of Turkish tribes abandoned the plains and settled in these valleys.

The Greeks became acquainted with the Caucasus at an early period, as the expedition of Jason and the mythology of Prometheus evidently show. But it seems that their knowledge was only derived from information collected by observing the W. portion of the range in navigating the Black Sea. None of their writers seem to have had a just idea of the position and extent of the range before the time of Strabo. Herodotus indeed (i. 203) describes the general position of the Caucasus with sufficient accuracy: he says, of all mountain-ranges the most extensive and the highest; and it contains numerous races of men, who live on the fruits of trees. These people ornament their dress with figures of animals, which they have the art of so fixing with certain vegetable colours in their woollen cloths, that they never wear or wash out. The detailed description in the 11th book of Strabo evidently shows that at his time the country to the S. of the Caucasus was well known. This was owing to the expedition of Pompey, who, in his war with Mithridates, advanced to the very foot of the range, and got possession of both banks of the Cyrus and Araxes. (Pallas, *Reineggs*, Biberstein, Engelhardt.)

CAUCUS, a word used in the United States of N. America to denote a meeting held by a political party for the purpose of securing the election of candidates for any office, or for the purpose of carrying any measure in a general meeting. The name Caucus originated in a dispute which occurred at Boston in New England, a short time previous to the revolution, between a party of English soldiers and some caulkers of the town, and which brought on a scuffle, in the course of which the soldiers fired and killed some of the citizens. The ferment which this occasioned led to meetings on the part of the latter, to determine upon the course most proper to be adopted in order to obtain redress from the government, and these meetings were on the part of the soldiers called Caulkers' meetings. The expression was soon corrupted to 'Caucus' meetings, and has since been used indiscriminately to designate preparatory meetings of any kind; but its more common signification is that above described. (Stuart's *Three Years in North America*.)

CAUDEBEC. [SEINE INFÉRIEURE, DEPARTMENT OF.]

CAUDISONA. [RATTLESNAKE.]

CAULIFLOWER, a kind of esculent vegetable consisting of the fleshy young undeveloped inflorescence of a variety of *Brassica oleracea*, and is hardly different from brocoli, except in being whiter and less hardy. It is said to have been imported from Cyprus about the middle of the sixteenth century. A very rich light warm soil is required for cauliflowers, which must be sown in beds and afterwards transplanted into sheltered situations where they can be protected when young with hand-glasses. They are sown in August for a spring crop, in February for a summer crop, and in May in order to come in at the end of autumn and beginning of winter. Ample directions for their management are given in all books on gardening.

CAUSATION signifies etymologically the action of a cause in producing an effect. The theory of causation (*Essai sur la Psychologie*, Paris, 1755) necessarily suppose three indispensable conditions: 1st. Two objects (agent and patient); 2ndly. Three changes (that of the agent? reason of the effect—that of the patient; effect of the action—that which the patient produces on the agent—effect of reaction); 3rdly. Four distinct moments (1. . . which precedes the action—that in which the action begins—that of the reaction—and that after the reaction). The subject of causation has always been one on which the most subtle thinkers have exerted their powers of analysis; but, as in every similar research after final principles which cannot be the effort of the understanding be clearly discerned and defined, opinions remain still as conflicting as when the inquiry first began. The student, in wandering through the mazes of metaphysical dogmatism, is disposed to turn from a subject on which so much has been said and so little determined: he finds that the statements of writers consist either of that which every one already knows, or of that which no one can at all understand. It appears to be agreed that, though in every instance we actually perceive something more than that the event, change, or phenomenon always follows the event, change, or phenomenon A, yet that we naturally believe in the existence of some unknown quality or circumstance belonging to the antecedent A, in virtue of which the consequent B always has been, is, and will be produced. The fact of magnetic attraction is usually adduced in illustration of causative influence: and the inquiry, why does the magnet move the iron? suggests the idea of that quality which is denoted by the word *power*; about the nature of which metaphysicians have always disagreed, and their dispute remains still unsettled. It is this attributed efficiency in the uniform antecedent of a change which philosophers have considered as forming the relation of cause and effect; and their endeavour to express the conception of this hypothetic quality has occasioned the employment of a great variety of terms, as energy, faculty, influence, capacity, ability, virtue, force, possibility, fitness, aptitude, &c. The following citations and references may be serviceable to those who desire to examine the learning of the subject. An account of the ancient division of causes into efficient, material, final, and formal, with all the subtleties of the Peripatetic school, is given in Lord Monboddo's *Antient Metaphysics*, 4to. vol. i., p. 33-311; vol. ii., p. 212; and as a choice specimen of the later scholastic doctrine and categorical arrangement of causes, see *Methodus cognoscendi Causas*, auctore Thom. Isacio, 12mo., 1650. 'Cause et effectus respondent potentia et actus—illæ eadem sunt res.' (Hobbes, *Opera Philos.*, c. ix., *De Causa et Effectu*.) The following discrimination is important: 'Potentia agentis et causa efficiens (c. x. *De Potentia*), idem sunt re, different autem consideratione; causa enim dicitur respectu effectus jam producti, potentia vero respectu ejusdem effectus producentis: ita ut causa preteritum, potentia futurum respiciat.'—'All conception of future (ibid., *Huan. Nat.*) is a conception of power able to produce something—we so far conceive that anything will be hereafter as we know that there is something at present that hath power to produce it; and that anything hath power to produce another thing hereafter, we cannot conceive but by remembrance that it hath produced the like heretofore—power simply is the excess of the power of one (the agent) above that of another (the patient).' 'The idea of power (Locke, b. ii. c. 21, *Of Power*) is that of possibility, faculty, ability to make any change—all power relates to action—power is not the agent, but the relation (of an object to its future action)—how mind excites motion by the power of thought, and how body communicates motion by the power of impulse, we are equally in the dark, (c. xxiii.)—to have the idea of cause and effect it suffices to consider any thing as beginning to exist by the operation of some other, without knowing the manner of that operation (c. xxvi. *Of Cause and Effect*, and see c. xxv. *Of Relation*). The far-famed and much-disputed, though not original, opinions of Hume, which, with some slight modification, have been adopted by Dugald Stewart, Dr. Brown, and others, are contained in sec. 4, 5, 6, 7, 8, 11, of his *Philos. Essays*, from which the following passages are taken. Consistency is not to be looked for in Essays, professedly paradoxical and designed less for the development of truth than as ingenious specimens of the dialectic art. 'We suppose,' says Hume, 'there is a connection between cause and effect; a power in the one by which it infallibly produces the other—power is that circumstance in

the cause by which it is enabled to produce the effect—when we consider the unknown circumstance of an object by which the degree or quantity of its effect is fixed and determined, we call that its power—the effect is the measure of the power—the utmost scrutiny can never discover but one event following another, without being able to comprehend any power by which the cause operates—no rational philosopher has ever pretended to assign the ultimate cause of any natural operation, or to show the action of that power which produces any effect; these ultimate principles are totally shut up from human inquiry—the power of the will in effecting animal motion is unknown and inconceivable; we are ignorant how bodies act on bodies, and how mind acts on itself and on body—it is a thing entirely incomprehensible—we have no idea of power at all: it is a word absolutely without any meaning either in philosophy or common life—were our ignorance therefore a good reason for rejecting any thing, we should deny all energy in the Supreme Being as much as in matter; experience only teaches us how one event consequently follows another, without instructing us in the secret connection which binds them together; we know nothing more of causation of any kind than merely the constant conjunction of objects: all events seem entirely loose and separate; one follows another, but we never can observe any tie between them: all we know of the matter is, that a cause is that after not by which anything constantly exists—it is an object followed by another, and where all the objects similar to the first are followed by objects similar to the second, where if the first had not been the second never had existed—it is absolutely impracticable to define a cause without comprehending as a part of the definition a necessary connection with its effect—belief of similar effects from similar causes is a natural instinct which reasoning can neither produce nor prevent.' From observations so full of at least apparent contradiction, it is not surprising that both the denial and admission of the principle of causative power are imputed to their author by different writers. Many of the works written in refutation of Hume contain ingenious remarks, though little of discovery. (Beattie *On Truth*, c. v.; Oswald, Priestley.) By Dr. Reid, Hume's opinion of power as having no objective reality beyond the imagination, is strongly opposed. (*Intellectual Powers*, 1827, p. 440-459). 'The notion of power, it is said, is one of our earliest abstractions, a notion the most explicit and universal, for the expression of which all languages have distinct and appropriate words.' The remarks of Dr. Price (*Moral Questions*, p. 29) deserve attention: 'What can do nothing—what is fitted to answer no purpose, has no dependence, aptitude, or power—can be nothing real—the whole meaning of accounting for a fact implies something in the nature of objects or events that connects them, a fitness to influence one another.' Price, Reid, Newton, and most writers on the subject, agree that where there is no substance there is no power, that is, that all power is the power of something; but by Sir Wm. Drummond (*Deidern. Questions*, 4to., p. 10) and some others, it is contended that power is not an attribute, but an independent primary indemonstrable principle, the cause of all things: and that we can possess a notion of the existence of it, as of the *ris movendi*, without any notion of its nature.' The opinions of Dr. Stewart on the subject are not remarkable either for novelty or consistency. (*Elements of Philos.*, vol. i. and ii.) 'In every change we have an irresistible conviction of the operation of some cause—it is a law of our nature; the mental association of cause and effect is of a most indissoluble nature—the idea of cause or power necessarily accompanies the perception of change—the human mind surely has a natural bias to conceive things as somehow linked together; possessed of powers and virtues which fit them to produce particular effects: but that we have no reason to believe this, is evident on a moment's reflection—it is a prejudice.' Along with this declaration is enforced the propriety of distinguishing physical from final or efficient causes, that is, from those 'powers and virtues' which are declared to have no existence. 'There may be,' says Dr. Stewart, 'no necessary connection among any phenomena we observe; the doctrine of necessity depends upon the truth of the proposition that every change has a cause with which it is necessarily connected. But what is meant by necessary unless that which cannot be varied or avoided? And only this may be predicated of human actions, if the laws of matter and mind are immutable, that is, if the course of nature does not change but continues to proceed in its established order, for then, as the universe exhibits an uniformity of sequence

in successive phenomena; or, in other words, consists of a series of uniform causes and effects, or *antecedents* and *consequents*, for the difference of name is quite unimportant, man *must*, in the nature of things, assuredly be the creature of circumstances, and *must* act as he is acted on.

The work of Dr. Thos. Brown, entitled 'An Enquiry into the Relation of Cause and Effect,' is well known as a specimen of superior metaphysical analysis. The main points of the theory it contains are given more concisely in one of Dr. B.'s Lectures, vol. i., p. 135, and a particular account of the work, with a notice of some objections to its doctrine, is given by the Rev. David Welsh in his 'Life of Dr. Brown' (p. 98 et seq., and notes I and N in dix.)

As this 'Enquiry' was originally designed expressly to vindicate and explain the theory of Mr. Hume, it cannot be expected to contain anything essentially, or importantly different; and that it does not is evident on a comparison of the leading propositions. Dr. B. perfectly coincides with Hume in maintaining that the relation of cause and effect is not known *a priori*, but from experience: and that after experience it is not discoverable by *reason*, but is merely an object of *belief*—a notion arising from 'an instinctive principle of faith.' Hume's assertion that, the *sentiment* of this relation is derived from experience only of the *customary* conjunction of objects, and arises merely from the mental act of *transition* from one object to the other, is contradicted by Dr. Brown; but Hume in his paradoxical humour has often incidentally done this for himself. The proposition of Hume that, *as to our knowledge*, there is 'nothing but one event or object *following* another,' is that which Dr. B. reiterates throughout the 600 pages of his treatise, in showing that, 'in a sequence of causes and effects, whether as to the phenomena of mind or of matter, there is absolutely nothing more than the antecedents and consequents themselves;' that the idea of power, when acutely analyzed, is simply the idea of *A* itself, as that which invariably, and without the intervention of anything whatever, is followed by *B*: the relation of things as to *power* being, in fact, their relation as to *time*: and the question about cause and effect, a question solely about the uniform priority and posteriority of events in time. The idea of action, force, and energy is also resolved into that of simple antecedent and consequent: so that all is reduced, as Hume has it, to one thing, not *by* but *after* another. This identification of the idea of power with that of an antecedent having an invariable relation to a consequent, only as to *time*, has been regarded by many as virtually a denial of the reality of what is named causal power; but Dr. B., no less than other philosophers, appears to have the same vague conception of an indefinable something which, known only by its operations, constitutes at once a latent portion of the whole qualities of an object, and forms its efficiency to create a certain uniform change in another. He says that power is the relation of a particular antecedent to the uniform change that follows, and that he feels this relation to be a fitness or aptitude in the former to produce the latter. He says that 'God formed objects with powers to be antecedents of changes;' that matter, like mind, is capable of beginning changes; and that we believe in the relation of cause and effect, 'not because we can demonstrate it to ourselves or to others, but because it is impossible for us to disbelieve it; the belief being in every instance intuitive.' But if proof be wanted that Dr. B. entertained an orthodox notion of power as a productive principle, it is given in the positive assertion of his personal friend and biographer, the Rev. Mr. Welsh (p. 131), who says, that were his theory of causation *really* deficient in this particular, instead of commending he should reject it as 'a monstrous heresy.' If this be so, it is amusing to see Dr. Brown reprimanding Dr. Reid for dealing in 'a tissue of distinctions merely verbal,' about 'a mysterious unintelligible something.' The truth is, that *power* is merely a name for human ignorance: the mind feels uneasy and dissatisfied in contemplating the unaccountable gap between an antecedent and consequent, and readily adopts any hypothesis that will put a bridge over it; hence the *power* of gravitation, the *power* of volition, &c. Dr. Brown's definition of cause as that which *immediately* as well as *invariably* precedes a change involves an obvious *petitio principii*: for the question is whether *B* really is immediate to *A*, as known to us? whether there exists a third co-efficient to causation? but this question can never be answered.

Of the numerous strictures which have appeared on the

theory of Dr. Brown, we may notice the two following:—'An Essay upon the Relation of Cause and Effect, contravening the doctrine of Hume,' by John Lawrance, 8vo. 1834. The author contends that antecedents and consequents are not essential to the proper relation of cause and effect; he cause, although an object, in order to act as a cause, must exist antecedently to such action, yet that when it does act as a cause, its effects are synchronous with that action, and are included in it; that it is not mere sentiment, but reason (the faculty of perceiving the *ratios* of things), which produces the conviction that everything which begins to exist must have a cause; and which forces the mind to perceive that similar causes must necessarily have similar effects; that nature cannot, without a contradiction of terms, be conceived to alter her course, and therefore that no other change could ensue than that which, in any given instance, does ensue; and that we derive, from the observation of changes, and from the operation of reason, the notion of that producing principle which we denominate *power*. In the translation, by Mr. Henry, of the 'Elements of Psychology,' by Victor Cousin, 1834, the theory of Hume and Brown is considered as asserting an unconnected succession of phenomena, without the admission of any idea of causative efficiency: some elaborate remarks of the translator, in accordance with the doctrine of the author, are therefore given to exhibit its 'falsehood and fallacy.' It is said that Dr. Brown confuses and mistakes the two distinctly different conceptions of *uniform antecedence* and *causation*; that he takes the former, which is only a *condition* of the idea of causation, for the idea of causation itself, which includes something *more* and *different*, as proved by the consciousness of the relation of muscular motion to the act of volition, and by the usages of all languages, &c., that the idea of cause is that of a doer, actor, producer, changer, mover; and that the degree of motion produced is correspondent to the degree of causative power exerted. An exposition of the doctrine of causation adopted in the transcendental theory of Kant may be found in the article on philosophy by Thomas Wugman, vol. xx. 'Encyclop. Londinensis' (see 'Causation' in Index, p. 252). By the Kantians the conception of the relation of cause and effect is considered as a *synthetical judgment a priori*—a postulate of pure reason. It is a remarkable fact in the history of metaphysical science, that the speculations of Hume on the idea of causation suggested to Kant the first notion of his system of transcendental ideas, that is, ideas which possess the character of universality and necessity. By Dr. Abercrombie, in his work on the intellectual powers, 1832, the subject of causation is considered as belonging to those 'first truths,' any demonstration of which it is absurdity to attempt (pp. 187-208-214). The following citation is from a learned metaphysical work (Hartley on Philosophical Criticism, 4to. 1810):—'All relation of necessity exists in some quality, property, or attribute which is common to the things related; if things be related as cause and effect, such relation must belong to the predicaments of action and passion: all action implies motion either of body or mind; it is *motion* therefore which, being communicated, is common to the two objects, and is that which constitutes the relation of cause and effect.' It would be endless to enumerate works in which the subject of causation is discussed. The treatise of M. Maine de Biran on the relation of cause and effect is highly commended by Cousin. Many works on natural theology and free-will contain more or less on the subject—Hobbes, Clarke, Leibnitz, Collins, Hume, Butler, Cudworth, Edwards, Copeland, &c.

CAUSE (in Natural Philosophy). We have here only to explain the manner in which this word is used, and not to enter into any speculation upon the connexion of cause and effect. In common language we say that *A* is the cause of *B*, when we have observed that *B* never appears without *A* having preceded, and also that *A* is always followed by *B*. And, generally speaking, we are in the habit of assuming the phenomenon which comes first to be the cause, and that which comes afterwards, the effect. In natural philosophy, the word cause is used in two senses, which may be distinguished into true and hypothetical; and it is found convenient for distinction to latinize the former term into *vera causa*. By a *vera causa*, or true cause, is meant the word cause used in the ordinary sense, namely, that which is actually concerned in producing the effect. Thus the rotation of the earth is a *vera causa* in the production of day and night; and in the article ATTRACTION the notion defined under the

words *physical attraction* is the supposition that attraction is a *vera causa* in the production of the celestial motions.

There are two different ways in which the word cause is used in the sense which we distinguish by the word *hypothetical*. The first is when we are able to prove that phenomena take place exactly in the manner and to the extent which would necessarily be if a certain supposition were true; so that we cannot be led into error as to results, if we assume that supposition to be true. Thus the supposition of the stars being all fixed in an immense crystal sphere, which sphere is turned round from east to west, is one from which the apparent motions of the stars, such as they are, would necessarily follow, and, being frequently applied to the explanation of the details of the heavenly motions, is then assumed as an hypothetical cause. And when it is found that the motions of all the planets are precisely such as would take place if the sun attracted them all, and they each other, as implied in the word gravitation, then the attraction which is sufficient to produce the effects in question is assumed as an hypothetical cause. Thus in the old disputes about the motion of the earth, each side admitted that the other produced an unobjectionable hypothetical cause, and the point in question was, which had the *vera causa*. And formerly it was discussed whether gravitation was a primary quality of matter, or whether the intermediation of other matter was employed. The second supposition involved the attempt to explain gravitation, by introducing some other quality of matter as the *vera causa*, in place of the hypothetical attraction. And the doctrine of immaterialism [BERKELEY] is an attack upon the notion of matter as a *vera causa* for the phenomena of the external world, though as an hypothetical cause it is admitted as an unobjectionable mode of speaking.

Secondly, a phenomenon is cited as the hypothetical cause of another, when the two are always found together, and the nature and quantity of the second are connected by an invariable law with the nature and quantity of the first. In this sense we have seen, in the article CAPILLARY ATTRACTION, that because convexity and depression always go together, and also concavity and elevation, the depression is referred to convexity, and the elevation to concavity, by the same sort of language as would be used if the first of each couple were the *vera causa* of the second. This is a language of convenience, but is apt to be misinterpreted.

Questions as to whether hypothetical causes are true or not, do not now occupy the attention of philosophers to the extent which was formerly the case. When the motions observed to exist in any system are sufficiently known, the pressures or other admissible species of action which would be sufficient to produce these motions are at once substituted as hypothetical causes. Thus, though the connexion between magnetism and electricity renders it an object of curiosity to trace them to some common hypothesis, few, we imagine, would attempt to find the cause of magnetism in the sense of the *vera causa*. It is otherwise when an hypothetical cause is found not to be sufficient to produce all observed effects. For example, the undulatory theory of light has prevailed over the emanatory, not because we have less reason to suppose that light is an emanation of particles from the sun and stars than existed a hundred years ago; but because it is found that many lately discovered facts are not such as would be true if light were an emanation, but are such as would be true if it consisted in undulations excited in an elastic medium. And though this cannot but favour the supposition that the undulations are the *vera causa*, yet that remains only a probability: the certainty is that the phenomena of the reflexion, polarization, &c., as hitherto observed, are all such as would necessarily follow, if the theory of undulations were true.

It must appear at first that this application of the word cause makes the ultimate end of natural philosophy much less imposing, if not less important, than the more common idea; which consists in supposing that the reasons (*vera cause*) of phenomena are discovered. But whether this be so or not, it is the only rational and demonstrable method of using the word. And it must be observed that all similar phenomena are thus, as it were, bound up together, and made to belong to one system. If then we refuse to say, with many popular works on physics, that 'Newton was the first who found out why water runs down hill,' we conceive that we are not altogether without a substitute when we say, that Newton was the first who connected the motion of water down hill with all the motions in the solar system

in such a manner that any new information as to any one of them can be extended to all.

But the great use of hypothetical causes lies in this, that they tell us, as long as they last, what to look for. The cause being assumed, the application of mathematics points out the time or circumstances under which to look for new phenomena, or at old ones in a new method. Thus several phenomena with regard to light, which might have remained long unobserved, have been predicted by computation from the undulatory theory, and subsequently verified. And in the planetary system, several motions too small to be easily detected, except by a person who previously knows in what manner and at what time to watch for them, have been added by theory alone to the list, and verified by observation.

The language of causation is sometimes misapplied in this way: the proof that a thing is, is called the reason why it is. Thus we remember seeing in the notes to SIMPSON'S edition of Euclid an assertion that geometry gives the reason why two sides of a triangle are greater than the third, whereas we never could detect any thing more than the proof that they are so.

CAUSTIC (in Optics). When a number of rays proceeding from a point are reflected or refracted at or through any number of media, they will not, in most cases, be all thrown to the same point again, but will be dispersed in such a manner as all to touch some curve or surface depending for its form and position upon the position of the luminous point, and the form and position of the reflecting or refracting curve or surface. This curve is called the *caustic* of the surface. We shall now give a case of the most simple kind. A reflecting curve ABC of a semi-circular form receives rays coming from a point on BO produced, but at so great a distance, that they may be considered as parallels. The rays I, II, III, &c., strike the

semi-circle at (1), (2), (3), &c., and are then reflected in the directions (1)1, (2)2, (3)3, &c. The curve A-M-C, having a cusp at M, is constructed in such a manner that any ray whatsoever moving parallel to ZB, shall, after reflection at the circle, touch or graze this curve, which is therefore called the *caustic by reflection for parallel rays* of the semi-circle A-M-C. And the space A-M-Z will not be illuminated by any of the reflected rays coming from any point in A-B, but only by those which come from a part of B-C, which, after touching C-M, their branch of the caustic, proceed and cut through A-M. The consequence is, that the space A-M-C-B will be much more highly illuminated than the exterior space; an effect which may be rendered visible by placing a ring, with a bright interior surface, upon a table, in the sun-light. It will then become evident, by a

part of the table within the $\text{fig. of the form } AMCB$, becoming brighter than the rest, that the greater portion of the reflected light strikes the table within such a curve.

The point which it is of most importance to notice in relation to caustics is the following: it is usual to suppose, for the sake of convenience, that all reflected or refracted rays converge to a point. This is practically true; or rather we may say that such a number of rays are collected by mirrors and lenses so near to a point, that the effect of a complete convergence is produced. If we look at the diagram, we see that all the rays which enter between I and III are far from being nearly reflected to a point, but are scattered along the caustic from 1 to 3. But an equal number of rays entering between V and VI is collected between 5 and 6 on the caustic, very near to M. The consequence is, a sufficient convergence of rays near M to give a bright image of the luminous point whence the rays came, to the formation of which it is evident that only the parts of the mirror near B will be efficient. No curve except a parabola would, in the circumstances of the diagram, make every ray converge accurately to one point.

A complete theory of caustics would include that of telescopes and microscopes of every kind; but would be of no practical use, except so far as relates to the cusps and the parts of the curve near them. These curves were first considered by Tschirnhausen, who gave them their name, and afterwards by John Bernoulli. They are much treated of in the older English works on optics, in a geometrical manner. The algebraical question, in its most general form, has been investigated by Malus in his 'Théorie de la Double Réfraction,' Paris, 1810; and lately by Professor Hamilton in two papers on 'Systems of Rays,' published in the Transactions of the Royal Irish Academy. The question of EVOLUTES is nearly akin to that of Caustics.

CAUSTICS. [ESCHAROTICS.]

CAUX, a district under the old régime of Upper Normandy: according to some authorities, as the *Encyclopédie Méthodique*, it was bounded on the N. and W. by the sea and the Seine, on the S. by Le Vexin Normand, and the country of Bray, and on the E. by the river Bresle, which separates it from Picardie; but other authorities restrict it within narrower limits. It is a flat but rather elevated district, producing plenteous grain harvests, and having much pasture land. It is especially abundant in fruit; the villages and even the farm-houses are surrounded with orchards, and cider and perry are the common drink of the country. Besides the above-mentioned productions, flax and hemp are grown, and there is a good supply of vegetables, game, and fish. The poultry is in high repute.

The principal manufactures of the district are coarse brown linens for sail-cloth or packing, leather, paper, glass, &c. The atmosphere of the coast is foggy.

The women of this part of France are celebrated for their fine complexion and the peculiarity of their apparel. The capital of the district was Dieppe (population, in 1832, 16,016) according to some; but those who give to Caux a smaller extent make either Caudebec (population, in 1832, 2782 for the town, or 2832 for the whole commune) or Montivilliers (population, in 1832, 1988 for the town, or 3828 for the whole commune) the chief place.

Caux takes its name from the Caleti, who inhabited this district in the time of Julius Cæsar; they were a branch of the great Belgian race, but their power, as may be judged from their contingent of the forces confederated against Cæsar, was far inferior to that of many other tribes.

CAVAILLON, a town in the South of France, in the department of Vaucluse. It is on the right or N.E. bank of the Durance, about 18 or 20 miles above the outfall of that river; in $43^{\circ} 50'$ N. lat., $5^{\circ} 3'$ E. long. This town was known during the Roman dominion in Gaul by the name Cabello; and ancient writers are not agreed whether it was a town enjoying the *jus Latii*, or whether it was a Roman colony. It was in the country of the Cavares. There have been some remains of Roman antiquity discovered here; and there are probably even yet some remains of a triumphal arch at the entrance of the cellar of the former episcopal palace. Upon the downfall of the Roman empire, the town came into the hands of the Burgundians, afterwards of the Franks. In the middle ages, it was subject successively to counts of Arles and Provence, and the counts of Auvergne, until, with the rest of the county Venaissin, in which it is situated, it came into the hands of the pope. This had formerly a port on the Durance; but the inundations of that river, having changed its bed, the port has been destroyed.

The town of Cavillon, according to Expilly (a.n. 1762), has four gates, one of which was damaged by an earthquake in 1731; the streets are narrow and inconvenient. There were a cathedral and several religious houses; but the diocese was abolished at the Revolution, and the town is now included in the archiepiscopal diocese of Avignon; the religious houses have also been for the most part suppressed.

The population of the town, in 1832, was 3845; that of the whole commune, 6911. Among the inhabitants are many Jews. The chief trade is in the agricultural productions of the neighbouring district, which is remarkably fertile, owing to the rich mud deposited by the inundations of the Durance, and the care of the inhabitants in providing manure. The produce consists of green peas, artichokes, garlic, peaches, and mulberries.

CAVALIER was formerly an ordinary English term for a horse-soldier; but it has an additional and historical meaning by having been assumed by, or given to, the adherents of Charles I. in the civil war, to distinguish them from the Roundheads, the name given to the adherents of the Parliament.

CAVALIER, a work whose rampart is raised several feet above those of the fortress in which it is formed. It serves either to defile those ramparts from the fire of an enemy on a neighbouring height, or to afford a plunging fire into the trenches of the besiegers. It is generally constructed on the terreplein of what is called a full bastion, and sometimes upon the rampart of a curtain: its *ban*, on the plan, was originally semicircular; but the cavaliers in bastions are now built with straight faces and flanks parallel to those of the work in which they are placed.

A cavalier thus formed and situated is proposed by Cormontaigne as a retrenchment in a bastion. He recommends that on its exterior, along the two faces, there should be a ditch whose sides have revetments of masonry; and that the ditch should be defended by traverses connecting the faces of the cavalier with those of the bastion, near the shoulders of both.

Trench cavaliers are works raised by the besiegers on the glacis of a fortress, in order to enable them to direct a plunging fire of musketry into the covered-way. They are formed of gabions placed in tiers above each other and filled with earth.

CAVALIERI, BUONAVENTURA, was born at Milan in 1598, and entered into the order of Jesuits at an early age. He was afterwards professor at Bologna, and died there December 3, 1647. He was a pupil of Galileo, according to the testimony of his friend Riccioli, who professes himself much indebted to his assistance in his studies. But it is said that he did not obtain the professorship at Bologna, in spite of the strong recommendation of Galileo, until his skill in astrology had been duly certified. He was a victim to the gout both in hand and foot, and was confined almost entirely to his bed for twelve years before his death. There is an *éloge* of him by Frisi (quoted by Lacroix, *Biog. Univ.*). All his works were published at Bologna, being 'Specchio Ustonio,' &c. 1632; 'Directorium Generale Uranometricum,' 1632; 'Geometria Indivisibilibus Continuorum,' &c. 1635; 'Trigonometria Planæ et Sphærica,' 1635; 'Rota Planetaria,' 1640; 'Exercitationes Geometricæ Sex,' 1647.

If we may judge from a contemporary biographer, Ghilini, 'Teatro d'Uomini Letterati,' Cavalieri (or Cavalierius, as his name is usually latinized) must have enjoyed a remarkable reputation in his day. But he has descended to posterity solely through his method of *indivisibles*, one of the predecessors of the doctrine of fluxions, and which [BARROW, LEIBNITZ, DIFFERENTIAL CALCULUS] must be considered as one of the first attempts at an organized method of dealing with the difficulties of the solution of which Archimedes had given the first example. Cavalieri considers a line as composed of an infinite number of points, a surface of an infinite number of lines, and so on, as in the following sentence: 'Hinc manifestum est figuras planas nobis ad instar telæ parallelis sibi contextas concipiendas esse; solida vero ad instar librærum, qui parallelis foliis coæquantur. Cum vero in telâ sunt semper sibi, et in librâ semper sibi numero finita, habet [habent] enim aliquam exceptionem nobis in figuris planis lineæ, in solidis vero plana numero infinita... supponenda sunt.' This method, ab-

solutely considered, is defective and even erroneous but the error is of the same kind as that of Leibnitz, who considered a curve as composed of an infinite number of infinitely small chords, and a surface of infinitely small rectangles. The error in both is one which does not affect the result, for this reason, that it consists in using the simplifying effect of a certain supposition too early in the process, by which the logic of the investigation may be injured, but the result is not affected. For instance, Cavalierius would consider a right-angled triangle as follows. Let n be the number of points in the base, then the perpendiculars at these points are in arithmetical progression, $0, a, 2a, \text{Sec.} \dots na$: the sum of all of which is $\frac{1}{2}n(n+1)a$, or $\frac{1}{2}n.na$, throwing away $\frac{1}{2}na$ as inconsiderable compared with $\frac{1}{2}n.na$, when n is infinite. But $\frac{1}{2}n.na$ is simply $\frac{1}{2}$ base \times perpendicular. Compare this method (absurd and almost unintelligible as it is, in the literal sense of the terms) with the following. Divide the base (b) into n equal parts, each of which is therefore $\frac{b}{n}$. Let the perpendicular be p , consequently the perpendiculars at the extremities of the parts are $\frac{p}{n}, \frac{2p}{n} \dots$ up to $\frac{np}{n}$, and each multiplied by $\frac{b}{n}$, and the sum of the whole being taken, we have

$$\frac{b}{n} \left(\frac{p}{n} + \dots + \frac{np}{n} \right) = \frac{bp}{2} \frac{n^2 + n}{n^2} = \frac{bp}{2} \left(1 + \frac{1}{n} \right).$$

This is the sum of the inscribed rectangles, which (see the process in ACCELERATING FORCE) approaches without limit to the area of the triangle as n is increased without limit. But it approaches to $\frac{1}{2}bp$ on the same supposition: whence $\frac{1}{2}bp$ is the area of the triangle. Either method, with caution, might be made to give true results, and in an intelligible manner; but that of Cavalierius is very subject to error, and, we may say, requires a knowledge of better methods to understand it. But it is nevertheless the first attempt at generalization, and serves to illustrate the position maintained by us [Barrow], that neither the fluxions of Newton nor the infinitesimals of Leibnitz were the actual methods by means of which the Differential Calculus (as now known) was made powerful. Cavalierius, with the methods of development of Newton, might have established his title to the invention. But his algebra was very imperfect, even for his day: we cannot see proof, in 1647, that he had ever seen the writings of Vieta, who died in 1603. The celebrated Guldinus wrote against the method of indivisibles, and was answered by Cavalierius in the third of the *Exercitationes Geometricæ*. Roberval claimed the method as his own, but his first publications on the subject followed those of Cavalierius.

CAVALRY (remotely from the Latin *caballus*, 'a horse') is that class of troops which serve on horseback; and, in the British army, it consists of the two regiments of Life Guards, the royal regiment of Horse Guards, seven regiments of Dragoon Guards, and seventeen regiments of Light Dragoons, of which the 7th, 8th, 10th, and 15th are Hussars, and the 9th, 12th, 16th, and 17th are called Lancers.

Among the ancients, while warfare consisted in expeditions to remote places rather for plunder than conquest, a numerous cavalry was indispensable. In proportion however as the art of war improved, this class diminished in value: the strength of the Greek and Roman armies lay chiefly in the firm array of their foot-soldiers, and Follard observes that the most certain evidence of decline in the military character of a state is the existence of a numerous cavalry. A well-disciplined cavalry has however often turned the scale of fortune in war: cavalry contributed greatly to the conquests of Philip and Alexander, and the superiority of Scipio over Hannibal in cavalry was the cause of the victory at Zama. In modern times, Seidlitz gained by his cavalry the battle of Rosbach in 1757; and the victory at Wurzburg in 1796 was decided by the same arm.

In the early French monarchy, and in the Anglo-Saxon kingdoms of Britain, the men of wealth and noble birth distinguished themselves in the field from those of inferior rank by being well armed and mounted on horses. And during several centuries in which the poverty of the nations prevented princes from maintaining standing armies, and when the foot-soldiers were men undisciplined and ill-provided, and summoned from the plough to attend the sovereign for a short time only, it is evident that a class of comprehending those men who, by the tenure of

were required to serve in the wars at their own charges, and to bring into the field a number of dependents mounted like themselves, and trained in the daily practice of martial exercises, must have constituted almost the only efficient arm of battle.

In France the superior classes of these warriors bore the title of knights bannerets, and the others were designated knights of the second order, or bar-chevaliers. In those days the infantry, for the reason before mentioned, being held in little estimation, the strength of armies was denoted by the number of banners and pennons under which the knights and their attendants fought; victories also were distinguished only by the number of men of rank who had been slain or made prisoners.

But the power of the nobles becoming too great for the monarch, and their mutual jealousies constantly involving the nation in the miseries of civil war, Charles VII., in 1445, took advantage of the temporary tranquillity which reigned in France after the English had been compelled to abandon nearly the whole of that country, to reduce his military force. From that time the kings retained in constant pay fifteen companies, as they were called, each consisting of 600 horsemen, besides the young men bearing the title of archers and pages, who also in general fought on horseback, but were clothed in a lighter armour. The troops composing the companies appear to have been what would now be called gentlemen; and the esteem in which they held themselves is evident from the refusal of the Chevalier Bayard, on the ground of their quality, to unite them with the Landsquenets (German infantry) at the siege of Padua, in an assault proposed by the Emperor Maximilian to be made on the place.

More than a century before the time of Charles VII., the English cavalry in the pay of the state was divided by Edward III. (1324) into small bodies, commanded by officers called constables: and Grose observes, that the list of the army at St. Quintin (1557) is the first in which a body of cavalry is distinguished by the appellation of a troop: a name which is still given to the half of a squadron, or the eighth part of a full regiment.

The respectability of the French companies above mentioned seems to have declined from about the time of Francis II., men of a lower grade being then occasionally introduced, from the difficulty, it is said, of filling with men of high birth the ranks, which were become very numerous.

But the employment of artillery in the field deprived this heavy armed cavalry of all the advantages it possessed over the soldiers who fought on foot, and the latter were often enabled to maintain the combat after the horsemen were dismounted or forced to retire; hence they gradually rose in reputation, and the good discipline and conduct of the Swiss infantry in the Italian wars induced the French and Germans to augment the number of the troops of this class in their armies. From that time the cavalry, though always an essential arm in war, may be said to have been inferior in importance to the infantry.

It appears that light cavalry did not, before the age of Louis XII., exist as a distinct body having general officers and a staff; but Montluc, in the reign of that monarch, mentions a general of 1200 light horse; and the corps must have subsequently become numerous, for it is said that Henry II., in 1552, had 3000 such troops under his command in his expedition to Germany.

The dragoons are a species of light cavalry, trained to act either on horseback or on foot as may be required. Père Daniel ascribes their formation to the Maréchal de Brissac, when he commanded the French armies in Piedmont at the end of the sixteenth century. The practice of horsemen fighting on foot is however very ancient: the Roman cavalry are said to have done so at the battle of Cannæ, and Procopius relates that one of the generals of Justinian, in an engagement with the Persians, caused his horsemen to dismount, and oppose their lances to the enemy's cavalry. Dragoons appear to have been introduced into the English service before the middle of the seventeenth century; but the oldest regiment of dragoons in the army is that of the Scotch Greys, which was raised in 1681. Dragoons perform the duty of advanced guards and patrols; they escort convoys, and harass the enemy in his retreat; or, in reverses of fortune, they protect the dispersed and defeated infantry. The name Dragoon appears to come from the Latin *Dracōnarius*, the appellation given to a standard-bearer, who car-

ried a standard or colour with the figure of a dragon on it. (Ammianus Marcell. xx. 4; Vegetius, ii. 7.)

Hussars are also a species of light cavalry, which originally constituted the national militia of Poland and Hungary. In France they were formed into a corps in the time of Louis XIII., under the name of Hungarian cavalry; and the class of troops was subsequently adopted in this country. It is uncertain from whence they obtained their present denomination, but probably from the shout they formerly gave before beginning action. They are now employed to protect reconnoitring and foraging parties, and to serve as patrols.

The Lancers were introduced into the British service in order to correspond to the corps of what were called Polish Lancers in the French army. The long weapons carried by this class of troops were supposed to be of use in a charge against infantry; and the fluttering of the flag at its extremity, by alarming the horse, to give an advantage over a dragon otherwise armed.

In the late war a portion of the French cavalry was furnished with cuirasses, and, in imitation of them, the English Life Guards have since borne the same heavy armour. These troops carry only a sword and two pistols; the heavy cavalry in general carry carabines, pistols, and swords; and the light cavalry very small carabines, pistols, and sabres. A complete regiment of cavalry is divided into four squadrons, and each of these into two troops. The full strength of a troop is 80 men; and to each troop there is appointed a captain, a lieutenant, and a cornet.

CAVAN, an inland county of the province of Ulster in Ireland; bounded on the N. and N.E. by Fermanagh and Monaghan; on the S.E. and S. by Meath, an angle of Westmeath, and Longford; and on the W. by Leitrim. Length, N. to S., 22 Irish or 28 English miles; breadth, from S.E. to N.W., 40 Irish or 51 English miles; area 600 square English miles, or 384,181 statute acres. Gross population in 1821, 195,076; in 1832, 228,040.

Cavan is the southernmost county of Ulster. Stretching across the narrowest portion of Ireland, it extends on the E. to within 18 English miles of the Irish Sea at Dundalk; and on the W. to within 20 miles of the Atlantic at Sligo Bay. The county is in form an irregular oval. It rises into mountains of considerable height at its N.W. extremity, but more than two-thirds of its surface, although high and very irregular, present no elevations of any consequence. Slieve Russell, the highest point of the N.W. chain, forms, with the remainder of the Ballynageeragh Mountains, the southern boundary of the basin of Loch Erne, the chief feeders of which lake flow from this county. From Loch Gawnagh on the S., where Cavan joins the county of Longford, the river Erne flows northward, through Lough Oughter and Belturbet to the borders of Fermanagh, where, after nearly bisecting the county of Cavan, it enters Upper Loch Erne at the same point with the Woodford, a considerable stream which also crosses the county a little farther N. from a small lake on the borders of Leitrim. The Erne between Loch Oughter and Upper Loch Erne receives the waters of the Annalee, which, rising from two lakes on the borders of Monaghan, runs nearly W. through the flat country between Cootehill at its source and Butler's Bridge near its confluence. Lough Sheelin and Loch Ramor, or Virginia Water, are also two considerable lakes in this county; the first discharges its waters through Westmeath by the Inny, a feeder of the Shannon, the second through Meath by the Blackwater, a tributary of the Boyne. The chief lines of road are in the direction of the greatest length and breadth of the county, from Navan in Meath on the S.E., to Belturbet and Florence Court on the borders of Fermanagh on the N.W., and from Killeshandra on the S.W. to Cootehill on the N.E.; the point of intersection is at Cavan, the assize town, situated very nearly in the centre of the county. The cross-roads are generally ill-planned and in bad repair. There is no navigation in this county except between Belturbet and Loch Erne, but the Ulster Canal now in progress will open a communication between Belturbet and Loch Neagh.

The climate of Cavan is rather rainy and boisterous; in the mountainous district it is particularly severe; yet it is far from unwholesome in any part, the people being rather remarkable for health and longevity. The general formation of the district is schistose. A patch of granite about seven miles square occurs in the eastern part of the county, and

assists in explaining the broken character of the hills in that district, the presumption being that the granite extends, at no great distance under the grauwacke, from this point to the neighbouring granite district of Mourne, and to this is owing the contortion of the incumbent strata. These indurated schists occupy by much the greater portion of the county. Limestone is found towards the S., where Cavan borders on the central limestone plain of Ireland, but the quantity is very small. The whole county is rich in minerals. At Swanlinbar and Quilea, among the Ballynageeragh Mountains, are mines of coal and iron; lead and silver ore have been discovered near Ballyconnell in the same district; lead and copper occur near Cootehill; coarse manganese and ochres are found in different parts of the county in abundance. A strong vein of blind coal occurs at Shercock on the E. of the county, and at Ballyjamesduff, a village between Virginia and Cavan, indications of a vein of very good quality have been discovered. Excellent marl, fuller's earth, potter's clay, and brick-clay are abundant throughout the county. There are numerous mineral springs, particularly at Swanlinbar and Kingscourt. The latter place is situated on the eastern border of the county. The spring feeds a remarkable lake on the summit of an adjacent hill. The lake is about half a square rood in area, has no outlet, preserves a constant level, and never freezes. The water for about six feet from the surface is pure and clear, but lower down becomes gradually more and more muddy, until at a depth of about thirty feet it approaches to the consistence of tar. In this mud the healing virtue of the spring is supposed to reside, and it has been found particularly efficacious applied as poultices in scorbutic complaints. The depth has never been ascertained, but the pool is considered by the vulgar to be unfathomable. On the plain below is a chalybeate spring, which is also resorted to by invalids, but has no connexion with the pool above. The name of this pool in Irish is *Lough-an-leighagh*.

The soil of Cavan is described as being naturally cold, spongy, and inclined to rushes, but with proper draining and manuring it can be rendered highly productive. In the district watered by the Erne and its feeders the crops are luxuriant, and the face of the country rich and pleasing. In the mountainous country nothing can be poorer; plough-husbandry is totally unknown, and the crops, which consist of potatoes and a poor sort of black oats, are put in with a narrow-bladed spade called a *sloy*. In this part of the county there are few roads, and the slide car is still in general use. In both districts the dry stone fence is almost universal, quick and thorn hedges being only found in the farms of the wealthy or in the demesnes of the great resident proprietors. Such demesnes are however numerous, and some of them, particularly those of Lord Farnham near Killeshandra, and of Mr. Coote at Bellamont Forest, near Cootehill, are of great extent and of remarkable beauty. The farms in general are very small: this has arisen chiefly from the combination of agricultural and manufacturing pursuits, in which the peasantry have long been engaged, each small farmer having until lately been more or less employed in linen-weaving.

In 1802 the bleach greens of this county were large enough to bleach 91,000 webs of linen at a time, which, if in full employment, would employ a capital of 45,500*l*. This trade has declined here for some time back, but its revival in Antrim and Down is likely to render it again the staple trade of all Ulster. The ground in the lowlands is chiefly under tillage, but there is little wheat grown; potatoes, oats, and flax are the principal crops raised. Grain is almost universally sown in ridges, in consequence of the wetness of the soil. The corn-mills are small, and for the most part attached to the several estates, as manor mills, at which the tenants are obliged by their leases to grind. The breed of cattle is poor; but great exertions have been made of late by spirited resident proprietors to introduce an improved stock, as well as to better the system of farming by the example of green crops and stall feeding. Grazing is not pursued to any extent; and the wool worn in frieze by the peasantry is chiefly brought in a manufactured state out of Connaught. Of the whole, Cavan is an improving county, and from the peaceful and industrious character of the people is likely to continue so.

Cavan is divided into eight baronies, viz., Tullaghaw, comprising the mountainous district on the N.W.; Tullaghmore on the S.W., containing Killeshandra, a neat town

with a good linen market (population, 1139); Clonmoghagh and Castleraghan on the S., the latter with the small towns of Ballyjamesduff (pop. 863) and Virginia (pop. 930); Clonchee on the E., with the towns of Baliborough (pop. 1065) and Kingscourt (pop. 1616); Tullaghgravey on the N.E., with the thriving town of Cootehill (pop. 2239); Upper Loughitee on the N., with Belturbet (pop. 2026), and Lower Loughitee in the centre, with Cavan, the county town, a neat but small place, with a good gaol, court-house, and barracks, and a pop. of 284. Cavan town is a decayed corporation, which formerly returned two members to the Irish parliament, for the loss of which franchise, Theophilus Clements and Thomas Nesbitt, Esqs., received 15,000*l.* compensation at the Union. Belturbet was also a corporate town, but is similarly decayed. Cavan county contains 33 parishes, of which 29 are situated in the diocese of Kilmore, 3 in that of Ardagh, and 1 in that of Meath. The population of the county in 1831 was 113,174 males and 114,759 females; total, 227,933, forming 40,328 families, of which 31,051 were chiefly employed in agriculture, 4462 in trade, manufactures, and handicraft, and 4785 not included in either denomination; the number of inhabited houses was 38,917; of uninhabited houses, 1044; and of houses building, 488. The general proportion of religious denominations, as ascertained from the diocese of Kilmore, with which Cavan is nearly co-extensive, is about five Roman Catholics to one Protestant.

Cavan was antiently called *Breifne (Breun)*, by which name it is distinguished in the history of the Conquest, as being part of the territory of O'Rourke, the seduction of whose wife by Dermot Macmurrough was the proximate cause of Strongbow's invasion. It continued in the possession of the O'Reillys, a clan tributary to O'Rourke, down to the reign of Elizabeth, when the county was first made shire-ground by commissioners appointed by the lords justices (the Lord Chancellor Cusack and Sir Henry Wallop) about 1540.

On this occasion the boundaries of the baronies were fixed, and the whole county was divided among the native possessors, five baronies being allotted to different members of the O'Reilly family alone, with a reservation of 220 beeves as a chief rent to the crown. All the O'Reillys however having forfeited by rebellion, except Molmurry, who was killed on the queen's part at the battle of the Blackwater, and his daughter having failed in establishing her claim in consequence of certain informality in the proceedings of the above commission, the whole of Cavan reverted *de jure* to the crown, although in fact held for some years after by the natives. It was not till 1610, when six other counties in Ulster were forfeited by the attainer of O'Donnell and O'Neill, that this cheat of Cavan was insisted on; and it is more than probable that, but for the design of a general plantation of Ulster, the objections to the former allotment of the county would never have been urged. When proclamation was made that the natives should remove out of the precincts allotted to the British undertakers, a lawyer of the pale retained by them made an attempt to traverse the proceeding, for, says Sir John Davies, 'the inhabitants of this country do depend upon the English pale, where they have many acquaintances and alliances; by means whereof they have learned to look of a freehold, and of estates of inheritance, which the poor natives of Fermanagh and Tyrconnell could not speak of, although these men had no other nor better estate than they: that is, only a scrambling and transitory possession, at the pleasure of the chief of every sept.' Accordingly the Irish advocate attempted to show that although O'Reilly by his rebellion might have forfeited his chieftaincy and head-rents, yet his tenants who had not been in rebellion ought not on that account to be dispossessed of their holdings: arguing that these tenants at large had an inheritable interest in the land which no act of their chief could forfeit, and desiring leave for them to transfer the dues and duties forfeited by O'Reilly, to the crown, of which they sought to be tenants in his stead. To this the king's attorney general (Sir John Davies) replied, by showing, that as O'Reilly had the power of levying exactions at pleasure on the country, so man subject to such arbitrary taxation could be considered a freeholder; and that, even though O'Reilly's exactions might have left a beneficial interest in the land to such a man, yet no member of a community in which the practice of gavelkind prevailed could be said to have an inheritable estate therein; and that therefore O'Reilly was the only inheritor and freeholder of the coun-

try his attainer necessarily left the whole county to be holden immediately of the crown, the inhabitants being disposable of solely at the king's pleasure. Further, he argued, that the king was not only entitled in law to seize the whole country, but that he was bound in conscience and justified in honour in so doing: first, for the advancement of his subjects in religion and civilization, and for the improvement of the soil, which neither Christian policy nor conscience could suffer longer to lie waste and unproductive; and, secondly, by the examples of many famous kings and nations who had planted similar colonies 'in imitation of the skilful husbandman who doth remove his fruit-trees not with a purpose to extirpate and destroy them, but that they bring better and sweeter fruit after the transplantation.' With these arguments the natives were forced to be contented, and after stipulating for their new possessions on as liberal terms as they could obtain, vacated their former possessions to the extent of 52,324 English acres, of which about 38,000 acres were distributed among colonists of various denominations.

The introduction of a civilized and industrious population had soon the best effects in reclaiming the country, which up to this time had been waste and barbarous. Castles were built on all the chief undertakers' portions; the foundations of towns were laid at Virginia, Belturbet, and Ballyconnell, and of numerous considerable villages throughout all the low part of the county. The principal settlers were Hamiltons, Aughmuties, and Baines, from Scotland; Lamberts, Parsons, Ridgeways, and Butlers, from England; and the pale; and of the reinstated Irish the chief were O'Reillys. There is very little interest connected with the subsequent history of Cavan. The forfeitures consequent on the wars, commencing in 1641 and ending in 1690, extended only to 3830 acres, principally the estate of the baron of Slane, and worth no more than 558*l.* 16*s.* per annum, in which respect property in this county has undergone less change of hands than in any other county of Ireland.

In point of antiquities this county is barren; there are the remains of numerous raths, tumuli, castles, and religious houses, but none of them of any extent or historical interest. On the hill of Quilea near Swinlinbar, in the N.W. of the cou. was formerly the place of inauguration for Macguire R. of Fermanagh, and the spot is still regarded with superstitious veneration by the peasantry of this rude district.

The number of schools in Cavan in 1824 was 346; educating 17,897 young persons, of whom 4948 were Protestants, and 12,866 were Roman Catholics. In 1821 the number of scholars was only 8806; so that the amount of education has been more than doubled here within the short space of three years. The value of the landed produce of the county has been calculated at 1,204,000*l.* per annum; the rental to proprietors at 101,890*l.* per annum; the average rent of land to proprietors at 6*s.* per acre per annum, and to occupiers at 30*s.* per annum. Savings' banks have not yet made any great progress here, nor has a local press been found successful. The county returns two members to the imperial parliament, and has a constituency of 2392 voters. Lords Farnham, Headfort, and Lauesborough, and the families of Maxwell and Coote, are the principal proprietors.

The county expenses are levied by grand-jury assessment. The state of the poor, although much less wretched than in many other counties, and notwithstanding numerous private charities, is still such as to make a provision for the destitute very desirable.

(*Statistical Survey of the County of Cavan*, by Pynnar's Survey; *Parliamentary Reports and Papers*; *Trans. Geological Society*, vol. v.; and *Trans. of British Association*; Pettigrew and Oulton's *General Directory for Ireland*.)

CAVE, WILLIAM, an eminent scholar and divine, was born December 30th, 1637, at Evington in Leicestershire, where his father was rector of the parish. He was admitted at St. John's College, Cambridge, in 1653, took the degree of B.A. in 1656, and that of M.A. in 1660. In 1662 he was admitted to the vicarage of Islington in Middlesex, and some time after became one of the king's chaplains extraordinary. He took the degree of D.D. in 1672; and in 1679 was collated by the Archbishop of Canterbury to the rectory of Allhallows the Great, in Thames Street, London. In July, 1681, he was incorporated D.D. at Oxford; and in November, 1684, was installed canon of Wiffrid. He resigned his rectory of Allhallows in 1689, and his vicarage of

Islington in 1691, having on the 10th November, 1690, been admitted to the vicarage of Isleworth in Middlesex. He died at Windsor, on the 4th of August, 1713, and was buried in Islington Church, where a monument was erected to his memory. He published two single sermons, one preached before the Lord Mayor and citizens of London, November 4th, 1690, 4to., London, 1690; the other, preached before a King, Jan. 11th, 1698.

iv. 7. 4to., London, 1698. His works of greater importance are—1. 'Primitive Christianity,' in three parts, 8vo., London, 1672; reprinted several times since. 2. 'Tabulæ Ecclesiasticæ, Tabulæ of the Ecclesiastical Writers,' fol., London, 1674; reprinted at Hamburg in 1676, without his knowledge. 3. 'Antiquitates Apostolicæ; or the Lives, Acts, and Martyrdoms of the Apostles,' fol., London, 1676; reprinted in 1702. 4. 'Apostolici; or the History of the Lives, Acts, Deaths, and Martyrdoms of those who were Contemporaries with or immediately succeeded the Apostles; as also of the most eminent of the Primitive Fathers for the first three hundred years: to which is added, a Chronology of the three first Ages of the Church,' fol., London, 1677. 5. 'Ecclesiastici; or the History of the Lives, Acts, Deaths, and Writings of the most eminent Fathers of the Church that flourished in the fourth century,' fol., London, 1682. 6. 'A Dissertation concerning the Government of the Ancient Church,' 8vo., London, 1683. 7. 'A serious Exhortation, with some important Advices, relating to the late cases about Conformity, recommended to the Protestant Dissenters from the Church of England,' 4to., London, 1673. 8. 'Chartophylax Ecclesiasticus,' 8vo., London, 1685. 9. 'Scriptorum Ecclesiasticorum Historia Literaria a Christo nato usque ad Sæculum xiv. facili methodo digesta,' in two parts, fol., the first printed at London in 1688; the second in 1698; republished, fol., Col. Allob., 1705 and 1720. The best edition is that printed at the Clarendon press, by subscription, in two vols., fol., 1740—1743; it contains the author's last corrections and additions. Cave's 'Lives of the Apostles,' 'Lives of the Fathers,' and his 'Primitive Christianity,' are justly esteemed the best books upon those subjects. (*Biogr. Britannica*; Chalmers's *Biogr. Dict.*; Nelson's *Hist. of Islington*, 4to., London, 1811, pp. 284, 285.)

CAVE, EDWARD, a printer to whom the literary world owes many obligations, was born at Newton in Warwickshire, February 29, 1691. He is principally known as the projector of the 'Gentleman's Magazine,' and as the friend and early patron of Dr. Samuel Johnson, who wrote an account of his life. He died January 10, 1754.

CAVEAT. As a general term in law, a caveat denotes a formal notice or caution given, by a party interested, to a court, judge, or public officer against the performance of certain judicial or ministerial acts. Thus caveats in this general sense were entered formerly in the Court of Chancery against the passing of a patent; and in the Court of Common Pleas against the levying of a fine. In a more confined and technical sense, a caveat signifies, 1. a caution entered in the Spiritual Court to stop the granting of probates of wills or of administrations; and 2. a notice given to the bishop by a party who disputes a particular right of presentation, to prevent the institution of a clerk to a benefice. A caveat in either of these cases is said to be binding (*servare jus illatum*) by the canon law for three months; and a probate given, or an institution made, pending the caveat, has been considered as wholly void by that law. But the common law takes no notice whatever of a caveat, considering the proceeding not as the act of a superior authority, but merely in the nature of an *ex parte* caution or suggestion from a stranger for the information of the court or officer, in order to prevent wrong from being done. The better opinion therefore seems to be, that administration granted, or institution made, notwithstanding a caveat, would be good at common law. (*Burn's Ecclesiastical Law*, tit. 'Caveat'; *Williams's Treatise of Executors*, vol. i.)

CAVENDISH, or CAVENDISH, THOMAS, was the son of a gentleman of fortune in Suffolk. It appears from Harris that he was of age, and inherited his father's property in 1585, immediately after which he equipped a 'stout bark of 120 tons' on his own account, and accompanied the famous Sir Richard Granville in his voyage to Virginia and the West Indies. His outlay on this voyage was a serious incroachment on his fortune; he derived no profit from it, unless we consider in that light the wonderful accounts he heard in the West Indies of the exploits of Sir Francis Drake, who

a short time before had plundered St. Domingo, Carthage, and other Spanish settlements, and the encouraging prospect of such enriching expeditions being easy of execution to a small determined force. According to some of his biographers, Cavendish, on his return from Virginia, still further reduced his property by becoming a courtier, and embarking in the extravagances of the gallants of Queen Elizabeth's days, and they state that his first grand voyage was undertaken (as the second undoubtedly was) to recruit his finances. The practice was common enough in his time, and men of rank and family thought it no disgrace to retrieve their fortunes by plundering on the Spanish Main. Their system seems to us to be little better than that of buccaneering; but the cruelties of the Spaniards almost justified even the buccaneers. In the days of Elizabeth too there was open war with Spain, and while that power sent armadas to invade England, it was quite fair that England should attack Spain in the richest and most exposed of her transatlantic colonies.

The expedition, which was mainly fitted out at the expense of Cavendish, who sold or mortgaged the remainder of his estates for the purpose, consisted only of three small vessels, one of 120 tons, one of 60, and the third of 40, and the united crews, men and officers, did not exceed 121. But the mind of every one of these adventurers was inflamed with ideas of wealth to be obtained in a predatory voyage against the Spaniards, and they had full confidence in the valour and generosity of their young commander. Cavendish embarked in the largest ship, and sailed from Plymouth on the 21st of July, 1586. Crossing the Atlantic, he ran along all the continent of South America, as far as the Straits of Magalhaens, into which he boldly sailed on the 6th of January, 1587. It took him thirty-three days to clear the Straits, but part of that time was well employed in surveying the coasts, rocks, &c., which were hitherto little known. As soon as he reached the Pacific Ocean (24th February) he turned northward, and soon came to the scene of action which he had selected as likely to furnish most booty. The men fought and plundered bravely, but not without suffering considerable loss. They burnt Páña, Acapulco, and other settlements on or near the coast, they took some Spanish ships, destroyed others, and razed the sea-board of Chili, Peru, and New Spain. But the crowning blow of the expedition, and that on which Cavendish counted for wealth and honour, was the capture of the annual galleon, the *St. Anna*, which was loaded with valuable merchandise, and contained 122,000 Spanish dollars in hard cash. This ship was 700 tons burden, and well manned, yet, after lying in ambush for her under Cape Lucas on the coast of California, the English, whose number, small at first, was greatly reduced by battle and sickness, attacked her, and carried her by boarding. After this Cavendish, starting from California, crossed the Pacific to the Ladrone Islands; from the Ladrone he sailed through the Indian Archipelago and the Straits of Java to the Cape of Good Hope; from the Cape he made for England, and he reached Plymouth on the 9th of September, 1588, having been absent no more than two years, one month, and a few days.

The circumnavigation of the globe had not before been performed in so short a time. In addition to dispatch, Cavendish had the merit of making some geographical corrections: he reduced to its proper length the distance from Java to the Cape of Good Hope, which the Portuguese had greatly exaggerated, and he did a good deal, as already stated, towards the hydrography of the Straits of Magalhaens. He was also the first to point out to the English the local advantages of St. Helena, which before had been resorted to only by the Portuguese. He touched at that island, which he described as a delicious place, then covered with trees. On his return from this voyage he wrote a curious letter to Lord Hounsdon, a chamberlain and favourite of Queen Elizabeth. After telling the courtier how he had gained victory over her majesty's enemies, he sums up, 'I burnt and sunk 19 sail of ships, small and great; and all the villages and towns that ever I landed at I burned and spoiled.' Elizabeth knighted the successful depredator, and from the portion of the spoils that fell to his share as capitalist and commander, Sir Thomas Cavendish was said, in the language of the time, to have been 'rich enough to purchase a fair earldom.'

But in three years Cavendish was a poor man again, and to better his fortunes he once more turned his eyes to the New World. An expedition was prepared, not as formerly,

by himself almost alone, but bravery, and adventure—an his authority and proved fatal to discipline, for those who had contributed as much as he had, pretended to an equality of command with him. Quarrels and dissensions arose; and, in addition to this misfortune, the three ships and two barques, which are said to have been well equipped, had to encounter tempests not met with in the former voyage. Their only success was the capture of the town of Santos in Brazil; but their reverses were numerous. Cavendish was obliged by the malicious spirit of his men, to abandon his bold plan here. Worn out by disappointment and vexations of all kinds, the hardy navigator died at on his return towards England in 1593. (Harris, *Collection of Voyages and Travels*.)

CAVENDISH, HENRY. The materials for the personal life of Cavendish are as yet extremely scanty. We have found a very little in the *Gentleman's Magazine* for 1810, and much more in the *Biographie Universelle*, from the pen of M. Biot, an excellent authority as to the scientific part; but as he does not state his source of information as to the details of private life, we inclose what we have taken from thence in [].

Henry Cavendish was the younger son of Lord Charles Cavendish, the brother of the great-grandfather of the present Duke of Devonshire, and was born October 10, 1731. [He had originally a very moderate fortune, and his relatives were estranged from him by his determination not to enter upon public or political life; with the exception of an uncle, who, on his return from abroad in 1773, not being pleased with the conduct of the family towards Cavendish, made the latter heir to his fortune, which was very large.] Cavendish devoted himself to mathematics and chemistry, to which his attention was probably turned by his father, who was himself a cultivator of the sciences; but his success, or at least its evidence, did not come very early, for he was more than 35 years of age before he published any thing. He lived a retired life, and never married; his manners seem to have been eccentric, and to strangers very reserved. [His library was immense, and he fixed it at a distance from his own residence, that he might not be disturbed by those who came to consult it. His friends were allowed to take books, and he himself never withdrew a book without giving a receipt for it.] He died February 24, 1810, leaving more than a million sterling among different relations. The few accounts of him which have been published in England contain the usual quantity of praise; but nothing to mark any particular point of character. Of Cavendish as a philosopher, those who judge by the quantity of brilliant discoveries will not be able to form any opinion. His writings consist of a few papers in the *Philosophical Transactions*, from 1766 to 1809. But in these papers we find methods and results which have occasioned his being sometimes called the Newton of Chemistry. Without such hyperbole, it may safely be said that he was the first, and one of the most useful, of those who laid the foundation of the science in its modern form. At the time when his first paper appeared, pneumatic chemistry had hardly an existence. It is true that different gases were known, that is, had been obtained as results of chemical processes; but they were not recognised as distinct substances. It was thought they consisted of common air mixed with foreign matter: and it was not imagined, for instance, that the inflammable air produced by operating with one substance was the same as that from another. In 1766, Cavendish for the first time asserted and demonstrated that the fixed air (carbonic acid gas) was the same, whatever was the substance from which it was derived, and the same for the inflammable air (hydrogen), and that neither had the specific gravity of common air. He investigated for the first time the principal properties of the latter gas. In 1784, he completed the synthetical formation of water; that is, he found the moisture above mentioned, and discovered that the remaining gas, now therefore called nitrogen, was the constituent of the acid. He produced this substance by passing the electric spark through air over mercury, and saturating the result with a solution of potash, by which he obtained nitrate of potash, commonly called niter. The well-known experiment for the determination of the earth's density has been described in **ATTRACTION**; see also **DENSITY OF THE EARTH**. Cavendish also wrote on the elasticity

of the fluids, and on the division of atoms, and on the division of matter.

We resist the temptation to dwell on the article as an exact proportion to what the reputation of Cavendish deserves. The fundamental laws of chemistry are based on his chemical results, and his name is associated with the fame for the great accuracy of his experiments, and the (then) unapproachableness of his results. One writer asserts that every sentence he has written will bear microscopic examination. A French writer (and he should say affirms) that he furnished Lavoisier with the materials of his system; and Sir Humphry Davy, in a lecture delivered shortly after the death of Cavendish, said as follows: 'His processes were all of a finished and perfected by the hand of a master; they required no correction; and though many of them were performed in the very infancy of chemical science, yet their accuracy and their beauty have remained unimpaired amidst the progress of discovery.' The discoveries of Cavendish were not confined to his substances, both by analysis and synthesis, ascertained that the weight of his product was the sum of that of its components, and determined its specific gravity. He was the first who carried the mind and method of a mathematician into the field from which the alchemist not long retired, and in which the speculator still remains. And when we say the mind and methods of a mathematician, we do not deny that the inductive philosopher had already been there; but it was to remark phenomena not to measure quantities.

CAVERY, a river in the south of India, in the Coorg country among the Western Ghats, near the coast of Malabar, in 12° 20' N. lat., 4000 feet above the sea. It is not navigable, except for small boats. Its course is at first for a few miles to the N.E.; it then flows E.S.E. to Seringapatam, soon after which its course is more directly E., until it enters the Barramahall districts, after which, running nearly due S., it forms the eastern boundary of Coimbatore, towards the Carnatic frontier. At Trichinopoly it is divided into several branches, the most northern of which, under the name of the Cleroon, after a north-easterly course of about 80 miles, in which it forms the division between the southern and central Carnatic, falls into the sea at Devicotta. The whole course of the river is about 450 miles. The southern branches retain the original name of Cavery, and by means of canals and embankments are employed to fertilize the plains of Tanjore, which present one vast field of rice cultivation.

At Seringapatam, the Cavery forms an island upon which the city is built. The river is here rapid and rapid, and its channel is filled with rocks and fragments of granite. A rude and massy aqueduct, 20 feet wide, has been constructed, in order to supply the town with water from the river. This aqueduct serves also the purpose of a bridge. In North Coimbatore, the Cavery forms another island, called Sivana Samudra, near to which are two cataracts of extraordinary grandeur. The cataract of Gaugana Chuki occurs in the northern channel, where the water is precipitated over a perpendicular rock 200 feet high. By a projection from the rock, the fall is divided into two stages, the division being however scarcely discernible through the cloud of foam. The southern cataract is called Birra Chuki; the precipice over which the water falls is about 100 feet high, and forms part of the arch of a large circle down which the river is thrown in ten or twelve streams; that in the centre is the largest and most violent. The quantity of water in the river varies considerably, according to the season. The principal supply is derived from the rains in the Western Ghats in the month of May. In July, the stream is again filled by the monsoon rains on the coast of Coromandel. The coming down of the floods from the interior is celebrated by great festivities by the inhabitants of the Southern Ghats, who justly attribute to it the fertility of their fields.

(Buchanan's *Journey through Mysore*; Heyne's *Historical and Statistical Tracts on India*.)

CAVIA. [GUINEA PIG.]

CAVIAR, (French, *Caviar*, *Caviar*; German, *Kaviar*; Italian, *Caviario*, *Caviare*; Spanish, *Caviario*, *Caviar*;) an article of food prepared in Russia from the roes of some large fish, generally the sturgeon. The greater part of the caviar is prepared near the mouths of the Volga, and also at the mouths of the Danube, Dnieper, and the Don. In

the Caspian, the sturgeon arrives in great numbers in the Caspian, these fishes. The spawn of the largest of them is estimated to contain 3,000,000 of eggs; the eggs are both with and without scales. Caviar is prepared by removing the roes of the sturgeon; it is then pressed in a bag, and is then thoroughly dried, the salt being added into the head; it is then pressed in a bag, in order to remove the liquor; it is then packed in kegs, and is then ready for sale. The Caspian made on the shores of the Caspian is for the most part sent up the Volga to Moscow; that shipped from the Black Sea and Sea of Azov is bought at Astrakhan by the Armenians of Nakhichevan and the Caucasus. The shipments from those ports, in 1855, amounted to 45,852 poods, equal to 1,650,672 English pounds. This caviar is not so good as that which is made on the Caspian. The principal exports are to Italy; very little is brought to England. The shipments altogether form a small part of what is made; the consumption in Russia is very great in consequence of the three seasons of fasting which occur in the year. When of good quality, caviar is dry and of a brown colour; it is commonly eaten with oil and lemon juice.

A similar substance, called botargo, is prepared on the shores of the Mediterranean from the roes of a kind of mullet; the method of preparing it is very similar to that described above. (Thoko's *Hist. of Russia*; De Hagenmeister's *Report of the Commerce of New Russia, &c.*)

CAVOLINA. [PSILOMATA]

CAWNPOOR, a district in the province of Allahabad, between 26° and 27° N. lat. and 79° and 81° E. long., bounded on the N. by the Etawah district, on the E. by the reserved territories of the King of Oude, on the S. by the Jumna, and on the W. by the Ganges. This district is situated in the Doab, or the tract between the Ganges and the Jumna; and it occupies a segment of the plain which extends from the bay of Bengal northward to the mountains. The soil of about two-thirds of this district yields abundant harvests of maize, barley, and wheat, besides turnips, cabbages, and other European garden vegetables, together with grapes, peaches, and several other fruits which have been introduced by European residents; the sugar cane also grows luxuriantly. Irrigation is much practised, and the number of wells sink for that purpose is very great.

From a statistical report made in 1814, concerning this district, it appears that the number of villages which it then contained was 3439; its area 29,46,315 begas (nearly 1,000,000 acres), of which 17,68,745 were cultivated, 1,34,189 fit for cultivation, and 10,43,381 begas were wholly unproductive. The government assessment amounted to 27,36,297 ruppes (273,629*l.*), or about 9*s.* sterling per acre on the cultivated portion of the land; a very high assessment, which being subsequently found to be oppressive to the cultivators has been reduced.

The principal towns, besides Cawnpoor, the capital, are Resoulabad in 26° 40' N. lat., and 79° 40' E. long., about 30 miles S.S.W. from Kanoe; Jaujemoor in 26° 26' N. lat. and 80° 16' E. long., eight miles S.S.E. from the town of Cawnpoor; and Akbarpore in 26° 23' N. lat. and 79° 52' E. long., 25 miles W.S.W. from Cawnpoor.

CAWNPOOR, the capital of the district, is situated on the right bank of the Ganges in 26° 30' N. lat. and 80° 13' E. long. Cawnpoor is one of the largest military stations in India. The old town stands a short distance N.W. of the modern buildings, and higher up the Ganges. The principal street is composed of well-built brick houses two or three stories high, with balconies in front; the back parts of the town are built in a straggling manner and the houses are mean in size and appearance. There are many handsome shops in the principal street containing generally an abundant supply of European goods which are nearly as cheap as at Calcutta; articles of Indian manufacture are not more than half the

price. Stationed at Cawnpoor, being obliged to provide their own quarters, have built their houses, or *bungalows*, along the banks of the Ganges. Each of these bungalows is a detached building with a garden and plantation, surrounded by an upright mud wall as a defence against cattle and thieves. In the rainy season the Ganges is more than a mile in breadth, but in the dry season the river is shallow and several sand-banks are visible in its bed. At this dry season, which lasts from October to June,

a residence at Cawnpoor is extremely healthy, owing to the sultry heat of the climate and the dust. The soil of the country, says Dr. Tennant, affords many instances of battles lost or won by the direction of the windward position giving an army an advantage somewhat similar to the weather-gage in an action at sea. For this reason all the houses of Europeans have glass windows and officers are provided when they march with a frame of glass which they fix in the doors of their tents. (Tennant's *Indian Recreations*; *Report of the Committee of House of Commons on Affairs of India*.)

CAXTON, WILLIAM, who England owes the introduction of printing, was born, according to his own statement, in the Weald of Kent. Of the date of his birth nothing is known with certainty, though Oldys places it in 1412. Lewis and Oldys suppose that between his 13th and 18th years he was put apprentice to one Robert Large, a mercer or merchant of considerable eminence, who was afterwards successively sheriff and lord mayor of London and who, upon his death, in 1441, remembered Caxton in his will by a legacy of 20 marks. Caxton, at this time, had become a freeman of the Company of Mercers. His knowledge of business however induced him, either upon his own account or as agent of some merchant, to travel to the Low Countries for a short time. In 1464 we find him joined in a commission with one Robert Whitehill, to continue and confirm a treaty of trade and commerce between Edward IV. and Philip, Duke of Burgundy, or, if they found it necessary, to make a new one. They are styled in it ambassadors and special deputies. This commission at least affords a proof that Caxton had acquired a reputation for knowledge of business. Seven years afterwards Caxton describes himself as leading a life of ease, when, having no great charge or occupation, he set about finishing the translation of Raoul le Fevre's *Recueil des Histoires de Troye*, which he had commenced two years before, in 1469. The original was the first book he printed, and this translation the third. Of Caxton's pursuits and travels abroad we know little more than that in his peregrinations he confined himself, for the most part, to the countries of Brabant, Flanders, Holland, and Zealand, and finally entered into the service, or at least the household, of Margaret duchess of Burgundy, who encouraged him to finish his translation of Le Fevre's *History of Troy*, assisted him with her criticisms upon his English, and amply rewarded him upon the completion of his labour. From the prologues and epilogues of this work we discover that he was now somewhat advanced in years, and that he had learnt to exercise the art of printing, but by what steps he had acquired this knowledge cannot be discovered; his types only show that he acquired it in the Low Countries; he does not appear to have seen any of the beautiful productions of the Roman, Venetian, and Parisian presses before he had caused his own fount of letters to be cut.

The original of Raoul's *History*, the *Oration of John Russell* on Charles Duke of Burgundy being created a Knight of the Garter, and the *Translation of Raoul*, were, as far as we know, Caxton's three first works: the last finished in 1471. A Stanza by Wynkyn de Worde noticed in an edition of Bartholomæus de Proprietatibus Rerum printed by Caxton at Cologne (about 1470), but the actual existence of this edition is unknown. Nor has more certain information yet been obtained of the exact period of Caxton's return to his native country. The usual supposition has been that he brought the art of printing into England in 1474, and that this date is indicated by the figures which are united in the centre of his device as a printer. In 1477 however he had undoubtedly quitted the Low Countries and taken up his residence in the vicinity of Westminster Abbey, where and in which year he printed his *Dietes and Sayings of the Philosophers*. Stowe says he first exercised his business in an old chapel near the entrance of the Abbey, but a very curious placard, a copy of which, in Caxton's largest type, is now at Oxford in the late Mr. Douce's library, shows that he printed in the Almonry. It is as follows: 'If it pleased any man spiritual or temporel to bye only Dyces of two and three commemoracions of Salisturi yee enoynted after the forme of this present lettre which be wel and truly correct, late hym come to We monester in to the Almonrye at the reed pale and he shal have them good chepe. Supplicet colat. According to Bagford, Caxton's office was moved to King-street.

The evidence of Wynkyn de Worde in the colophon edition of *Vitas Patrum*, 1490, it appears that these

Lives of the Fathers were translated out of French into English by William Caxton of Westminster, lately dead, and that he finished the work 'at the last day of his life.' His death however seems fixed, by two or three entries in the parish accounts of St. Margaret Westminster, to the year 1491 or 1492, in which we read *Item; alle burying of William Caxton for iiii. torches vi. viii. Item; for the belle at same Bureyng, vi.* Wynkyn de Worde no doubt referred to this time.

Caxton, Mr. Warton observes, by translating, or procuring to be translated, a great number of books from the French, greatly contributed to promote the state of literature in England. In regard to his types, Dr. Dibdin says, he appears to have made use of five distinct sets, or founts of letters, of which, in his account of Caxton's works, he has engraved plates in fac-simile. Edward Rowe Mores, in his 'Dissertation upon English Typographical Founders and Founderies,' says Caxton's letter was originally of the sort called *Secretary*, and of this he had two founts; afterwards he came nearer to the *English face*, and had three founts of *Great Primer*, a rude one which he used anno 1474, another something better, and a third cut about 1482; one of *Double Pica*, good, which first appears 1490, and one of *Long Primer*, at least nearly agreeing with the bodies which have since been called by those names. All of Caxton's works were printed in what are called black letter.

The following is probably as complete a list as can now be recovered of the productions of Caxton's press:—1. 'Le Recueil des Histoires de Troyes,' compose par recuile le feure, chapelain de Monseigneur le duc Philippo de Bourgogne en l'an de grace mil ccccxlvi. fol. 2. 'Propositio clarissimi Oratoris Magistri Johannis Russell, decretorum doctoris ac adtunc Ambassiatoris Edwardi Regis Anglie et Francie ad illustr. Principem Karolum ducem Burgundie super susceptione ordinis garterij, &c.' 4to. 3. 'The Recuyell of the Historyes of Troye,' composed and drawen out of diverse bookes of latyn into Frenssh by Raoul le fleure in the yere 1464, and drawen out of frenssh into Englishhe by William Caxton at the commaundement of Margarete Duchesse of Bourgoigne, &c., whiche sayd translacion and werke was begonne in Brugis in 1468 and ended in the holy cyte of Colen 19 Sept. 1471, fol. 4. 'The Game and Playe of the Chesse,' translated out of the French, fynysshed the last day of Marche, 1474, fol. 5. A second edition of the same, fol. (with wood-cuts). 6. 'A Boke of the hooly Lyf of Jason,' (1475) fol. 7. 'The Dictes and notable wyse Sayenges of the Philosophers,' transl. out of Frenshe by lord Antoine Wydeville Erle Ryuyeres, empr. at Westmestre, 1477, fol. 8. 'The Morale Prouerbes of Cristyne (of Pisa), fol. 1478. 9. 'The Boke named Cordiale; or Memorare Novissima,' which treateth of 'The foure last Things,' begun 1478, finished 1480, fol. 10. 'The Chronicles of England,' Westm., 1480, fol. 11. 'Descripceion of Britayne,' 1480, fol. 12. 'The Mirroure of the World or thymage of the same,' 1481, fol. 13. 'The Historye of Reynart the Foxe,' 1481, fol. 14. 'The boke of Tullius de senectute, with Tullius de amicitia, and the Declamacyon, which laboureth to shew wherein Honour sholde reste,' 1481, fol. 15. 'Godefrey of Balyne; or, the laste Siege and Conqueste of Iherusalem,' Westm., 1481, fol. 16. 'The Polycronicon,' 1482, fol. 17. 'The Pylgremage of the Sowle,' transl. from the French, Westm., 1483, fol. 18. 'Liber Festalis, or Directions for keeping Feasts all the Yere,' Westm., 1483, fol. 19. 'Quatuor Sermones' (without date), fol. 20. 'Confessio Amantis,' that is to saye in Englishhe, 'The Confessyon of the Louer,' maad and compyled by Johan Gower, squyer, Westm., 1483, fol. 21. 'The Golden Legende,' Westm., 1483, fol. 22. Another edition of 'The Legende,' sin. folio. 23. A third, sin. at Westmestre, 20th May, 1483, fol. 24. 'The Booke callid Cathon' (Magnus), transl. fr. the French, 1483, fol. 25. 'Parvus Chato' (without printer's name or date, but in Caxton's type), folio. 26. 'The Knyght of the Toure,' transl. from the French; Westm. (1484), fol. 27. 'The Subtyl Historyes and Fables of Esope,' transl. from the French, 1484, fol. 28. 'The Boke of the Ordre of Chyvalrye, or Knyghthode,' transl. from the French (assigned to 1481), fol. 29. 'The Boke ryal; or the Boke for a Kyng,' 1484, fol. 30. 'A Boke of the noble Historyes of Kyng Arthur and of certen of his Knyghtes,' which booke was reduced in to Englishhe by syr Thomas Malory Knyght, 1485, fol. 31. 'The Lyf of Charles the Greate Kyng of Fraunce and Emperour of Rome,' 1485, fol. 32. Another edition of the same, 1485, fol. 33. 'Thymorye

of the noble ryght valyaunt and wo of the fayr Vyenne, the doulphyns doughty of Vyennoye,' transl. from the French, 1485, fol. 34. 'Maners,' 1486, fol. 35. 'The Doctrinall of Maners,' 1489, fol. 36. 'The Boke of Fayttes of Armes and of Chyvalrye,' transl. from the French, 1489, fol. 37. 'The Boke of Vegetius de Re Militari,' 1489, fol. 38. 'The Boke of Eneydos, compyled by Vyrgyle, translated from the French, 1490, fol. 39. 'The Tails of Cauntyrburye' (no date), fol. 40. Another edition (without date or place), fol. 41. 'Isaancia Salvatoris,' 4to. 42. 'The Boke of Consolacion of Philosophie,' whiche that Beccius made for his comferte and consolacion (no date nor place), fol. 43. A collection of Chaucer's and Lydgate's minor Poems, 4to. 44. 'The Boke of Fame, made by Gefferey Chaucer,' fol. 45. 'Troilus and Creseyde,' fol. 46. 'A Boke for Travellers,' fol. 47. 'The Lyf of St. Katharin of Senis,' fol. 48. 'Speculum Vite Christi; or the myrroure of the life of Ihesu Cristo,' fol. 49. 'Directorium Sacramentum; sive Ordinale secundum Usum Sarum, Westm., fol. 50. 'The Worke (or Court) of Sapience,' composed by John Lydgate, fol. 51. 'A Boke of divers Ghostly Matters,' Westm., fol. 52. 'The Curial made by Maystro Alain Charretier,' transl. from the French, fol. 53. 'The Lyf of our Lady, made by Dan John Lydgate, monke of Burye,' fol. 54. 'The Lyf of Saynt Wenefrydo, reduced into Englishhe, fol. 55. 'A Lytel Tretise, intituled or named The Lucidarye,' 4to. 56. 'Reverendissimi viri dñi. Guilelmi Lyndewadi, LLD. et epi Asaphensis, constitutiones provinciales Ecclesie Anglicane,' 24mo. 57. 'The Historye of Kyng Blanchardyne and Queen Eglantyne his wyfe,' fol. 58. 'The Siege of the noble and invincible Cytee of Rhodes,' fol. 59. 'Statuta apud Westmonasterium edita, anno primo Regis Ricardi tercii,' fol. 60. 'Statutes made in the 1st, 2nd, and 3rd Parliaments of Henry VII., folio. (The only fragment of this work, known consists of two leaves.) 61. 'The Accidence,' (mentioned in one of the sale catalogues of the library of T. Martin of Palgrave.) 62. 'The Prouffitable Boke of manes soule, called The Chastysing of Goddes Chyldern,' fol. 63. 'Horre, &c., 12mo., a fragment of eight pages now at Oxford, in the library bequeathed to the Bodleian by the late F. Douce, Esq. 64. A fragment of a Ballad, preserved in a volume of scraps and ballads in the British Museum.

Dr. Dibdin has included, among the printed works of Caxton, 'Ouyde his Booke of Metamorphose,' translated and fynysshed by me William Caxton at Westmestre the xxij. day of Apryll, the yere of our lord M. liij. C. liij. And the xx yere of the regne of Kyng Edward the fourth,' but it remains in manuscript only, as far as is known, in the Pepysian collection now deposited in Magdalen College, Cambridge, and consists of the last five books of the 'Metamorphoses' only. (Lewis's *Life of Caxton*, 8vo., Lond., 1737. Oidys' account of him in the *Biographia Britannica*; Warton's *Hist. Engl. Poetry*; the first volume of Dibdin's edit. of Ames's *Typogr. Antiquities*; and Chalmers's *Biogr. Dict.*) The two largest assemblages of the productions from Caxton's press now known, are those in the British Museum, and in Earl Spencer's library at Althorpe. The titles given in the present article have been collated with the books in the former of these collections.

CAYENNE. [GUIANA.]

CAYENNE PEPPER. [CAPSICUM.]

CAYLUS, COUNT, was born at Paris in 1692. He entered the army in his youth, and made some campaigns in Catalonia and in Germany. After the peace of Rastadt, he turned his attention entirely to the fine arts, and went to Italy for the purpose of studying them. He afterwards went to Constantinople and Asia Minor, and visited the ruins of Ephesus and Colophon. On his return to France, he applied himself to engrave, to illustrate the cameos and other stones of the 1st age, and to superintend the publication of the fine arts. 'Pierres gravées du Cabinet du Roi,' in two vols. folio, 1771, is a part of that collection. He also published engraving the medals of the Roman Emperors belonging to the same collection; 'Numismata aurea Imperatorum Romanorum e Cimeliis Regis Christianissimi.' In 1731 he was made a member of the Academy of Sculpture and Painting, upon which he wrote the lives of the most celebrated painters and sculptors who had belonged to that society. He caused the drawings of Santo Bartoli, of Rome, which are representations of

antient paintings, and mosaics, and form a very valuable collection of antient art, to be engraved and coloured. 'Recueil de peintures antiques imitées fidèlement pour les couleurs et pour le trait d'après les desseins coloriés faits par P. Santo Rocco' fol. Paris, 1757. The engravings are beautifully executed. The celebrated mosaic pavement of Palestrina is among them. In 1742 he was made a member of the Academy of Inscriptions, for which he wrote numerous memoirs on antient monuments, on antient paintings, on the Egyptian obelisks, on mummies, papyrus, &c. He collected numerous antiquos, and published the result of his investigations in his great work, 'Recueil d'antiquités Egyptiennes, Etrusques, Grecques, Romaines, et Gauloises,' 7 vols. 4to. The last volume was published in 1767, after his death; it contains a biographical notice of the author, by Le Beau. Caylus wrote also 'Nouveaux Sujets de Peinture et Sculpture,' 12mo., 1755; 'Mémoire sur la Peinture à l'Encaustique,' 8vo., 1755, which is a revival of the method of encaustic painting of the antients. He found out the means of incorporating the colour with stone. The art of encaustic painting has been practised since chiefly upon slate (that of the antients appears to have been upon wood), by Bachelier, Requeno, Fabbrini, and Parenti, the two last of whom are Florentine artists. (*Saggi sul Ristabilimento dell'Antica Arte de' Greci e Romani Pittori*; Parma, 1787, and also 'Notes to Winckelmann,' vol. ii., p. 80.) Caylus wrote several novels, which have no very great merit. He died at Paris, in 1765. He was a warm, and, as far as it was in his power, a liberal promoter of the arts; extremely disinterested himself, he sought out and assisted indigent talent. He left his rich collection of antiquities to the King's Museum. In 1805 a compilation of memoranda was published, under the title of 'Souvenirs du Comte de Caylus,' 2 vols. 12mo.

CAYMANS, three islands lying to the westward of Jamaica, from which the nearest is distant 72 miles. The largest and westernmost is called the Grand Cayman; the next, Little Cayman; and the easternmost, Cayman Brack. They are contained between the parallels of 19° 10' and 19° 45' N. lat., and the meridians of 79° 30' and 81° 35' W. long. Grand Cayman is 24 miles long and 2½ broad; it is low and covered with trees, chiefly coconut. On the western side is a large village, called George's Town; but the other portion of the island is thinly inhabited. There are among the inhabitants many descendants of the old buccaneers. Produce is raised more than sufficient for their own consumption, and vessels touching here may obtain supplies; but there are no cattle or sheep, and water is scarce. The climate is considered healthy. The natives employ themselves chiefly in catching turtle, for the supply of Jamaica and other islands.

Little Cayman and Cayman Brack are small, low, barren, and uninhabited. (*Columb. Navigator, and Recent Surveys.*)

CAYOPOLLIN. [*OROSSUM.*]

CAYOU. [*ATKES, Species 3.*]

CEBES, a Theban philosopher, and a disciple of Socrates. He was the writer of three dialogues, called 'Πῖναξ' (table or tablet), 'Ἐξέμνη', and 'Φέρνυχος' (Suidas v. Κέρης, Diog. Laërt. ii. 125.) He is represented by Plato as attending Socrates in his last moments, and is one of the interlocutors in the *Phædon*. The first mentioned of his dialogues has been very frequently edited, and is often one of the first books placed before the Greek student. It is a description of an allegorical picture, supposed to be affixed to the walls of a temple of Saturn, and representing the life and trials of mankind. Scholars have doubted whether it is rightly attributed to the Theban Cebes, but the Greek authorities are conclusive of its genuineness (see Lucian, tom. i. p. 702, and tom. iii. p. 5. *misæstheritis*); and the Attic dialogue in which it is written is no proof that its author was not a Theban; for the dialogues were always written in Attic, just as the Latin poets are appropriated to the spots, and the Doric to the persons. We know nothing of Cebes beyond the mention of his name by Plato, who makes Socrates call him a diligent inquirer after truth, and by Xenophon, from whom we learn that his moral character was most unexceptionable. The first complete edition of the 'Πῖναξ' is that by J. Gronovius, Amstel. 1689; the best are, perhaps, that by Schweighæuser, Lips. 1798, which also contains the *Manual of Epictetus*; and his last edition of 1806.

There was a Cebes of Cyzicus, a Stoic philosopher contemporary with the Emperor Marcus Aurelius, to whom

some critics, apparently without much reason, would attribute the 'Table.'

There is a dissertation on the genuineness of the 'Table,' by F. G. Klopfer, Zwickau, 1819, 4to.

CEBRIONITES (Lafreille), a family of Coleopterous insects, of the section *Malacoderma*. Technical characters:—Body generally somewhat oval and convex; wing cases rather soft and flexible; thorax broader than long, widest at the base, and with the hinder angles acute, or produced into a spine. Antennæ generally longer than the head and thorax; mandibles terminating in a simple point; joints of the palpi of nearly equal thickness; legs moderate, not contractile.

The species of this family are frequently found upon plants in marshy situations, but very little is known of their habits; their larvæ are supposed to live in the ground, and very probably subsist on the roots of plants.

The genus *Cebrio* is distinguished from other genera of this family by having all the joints of the tarsi entire, and without any velvet-like pellets beneath, and the posterior thighs of the same size as the anterior. About ten species of this genus have been discovered, most of which are peculiar to Europe. *Cebrio gigas*, a species not uncommon in France, is about three quarters of an inch in length, and of a pale brownish-yellow colour. In the male the head and thorax and the legs (excepting the thighs) are black; the head and thorax are thickly punctured, and, together with the elytra, which are striated, are covered with small yellowish hairs; the antennæ are long, and if extended backwards would reach about half way down the elytra. In the female there is so striking a difference in this organ, as to cause that sex to be mistaken for a distinct species: here the antennæ are very short, and if extended backwards would not reach farther than the base of the thorax; the basal joint is much longer than the other, the fourth and following joints are short, thick, and joined closely together. The legs of the female are also shorter and thicker in proportion than in the other sex.

It is said that the European species of this genus appear in great numbers after heavy rains.

CEBUS. [*SAPAJOU.*]

CECIDOMYIA, a genus of two-winged flies (order Diptera) of the family Tipulidæ. Technical characters:—Wings resting horizontally, and having three longitudinal nervures; head hemispherical; antennæ as long as the body, and generally twenty-four jointed, the joints hairy; (in the females fourteen-jointed;) the two basal joints short; legs long, basal joint of the tarsi very short, second long.

Mr. Stephens, in his catalogue of 'British Insects,' enumerates twenty-six species of this genus. They are always of small size, and many of them deposit their eggs on the young buds of various kinds of plants, where the larva is hatched, and transforms them into galls, in which it subsists and undergoes its metamorphosis.

Cecidomyia salicina is common in France on willows in the month of May; it is of a blackish colour, covered with fine velvet-like hairs; the antennæ have twenty joints; the wings are slightly obscure and downy; length one-sixth of an inch.

This little fly fixes each of its eggs on a bud of the willow in the month of June. The bud at the time of its evolution, near the end of the month, instead of putting forth its branch, becomes enlarged at the base, and ultimately forms a gall in which the larva is lodged, nourished, and undergoes its metamorphosis: the larva is of a reddish-yellow colour, and assumes the pupa state in the winter, when the gall is become of a large size.

Other species of cecidomyia produce similar deformities upon various parts of many species of plants, and resemble in this part of their habits the *cynipidæ* among the *hymenoptera*.

Cecidomyia tritici (*Tipula tritici*, Kirby), an insect commonly known by the name of the *Wheat-fly*, has occupied much of the attention of entomologists, particularly that of the Rev. W. Kirby, who has published two accounts of its habits in the *Linnæan Transactions*.

This little fly is about one-twelfth of an inch in length, and of a reddish-yellow colour; the wings are milk-white, and exhibit this prismatic colour in certain lights; the eyes are black. The wheat-fly may be observed sometimes in

* In order not to confound this with other little flies which may be some what similar, it will be necessary to notice the generic characters given in the beginning of this article.

the greatest abundance, flying about wheat-fields in the month of June. It generally makes its appearance about seven or eight o'clock in the evening. 'Although,' says Mr. Kirby, 'these insects are so numerous in the evening, yet in the morning not a single one is to be seen upon the wing; they do not however quit the field which is the scene of their employment. Upon shaking the stalks of the wheat or otherwise disturbing them, they will fly about near the ground in great numbers. I found their station of repose to be upon the lower part of the culm with their heads upwards.' The fly totally disappears by the end of June. According to Mr. Kirby it is about eight o'clock in the evening that they deposit their eggs. This gentleman has seen as many as twelve specimens thus occupied at the same time on a single ear, and observes that these flies are sometimes so numerous that were all to lay their eggs, and these to hatch, one half of the grain would be destroyed.

The eggs are deposited by means of a long pointed and contractile tube, or ovipositor, generally upon the interior valvule of the corolla, just above the stigmata, and it occasionally happens that the fly is unable to retract its ovipositor, and being thus held prisoner it dies.

About the middle of June the larvæ are hatched, and may be seen adhering to the lower end of one of the anthers, and sometimes immersed in the woolly summit of the germ, or in the interior of the valvule of the corolla. These larvæ are simple minute grubs without legs or any visible head, and of a yellowish colour, and their food consists of the pollen of the anthers, which it appears in the plants thus attacked is unfit for impregnation.

* The pupæ are of a reddish colour, and in number bear no proportion to that of the larvæ. 'I have seen,' says Mr. Kirby, 'more than once, seven or eight florets in an ear inhabited by the latter, and sometimes so many as thirty in a single floret, seldom less than eight or nine, and yet I have scarcely ever found more than one pupa in an ear, and had to examine several to meet with that.'

The pupæ that I have observed have generally been somewhat attached to the grain, and, what is worthy of notice, I never observed them within those florets where the larvæ had taken up their residence; they seem invariably to choose for their habitation, in their immediate state, one where the grain is uninjured, to which they may attach themselves.

In a field of fifteen acres (planted partly with white and partly with red wheat), which Mr. Kirby carefully examined, and which was much attacked by these insects, he calculated that the havoc done by them would amount to five coombs; he observed that the white wheat was most affected.

During Mr. Kirby's observations he discovered no less than three parasites among the Ichneumonidæ, on the larva of the insect in question, which accounts for the great difference between the number of larvæ and that of the pupæ.

For further information on this insect, we refer to the 'Transactions of the Linnean Society,' vol. iv. (in which there are two papers on the subject), pp. 224 and 230, and vol. v. p. 96.

CECIL WILLIAM, BARON BURLEIGH, was born at Bourne in Lincolnshire, September 13, 1520. His father was master of the robes to Henry VIII. He was placed successively at the grammar schools of Grantham and Stamford, and at the age of fifteen he was removed to St. John's College, Cambridge, where he was distinguished for the regularity of his conduct and the intensity of his application. At the age of sixteen he delivered a lecture on the logic of the schools, and three years afterwards another on the Greek language. At twenty-one he entered at Gray's Inn, and applied himself to the study of the law, the history of his own country, and especially the genealogy of its principal families. In August, 1541, he married a sister of Sir John Cheke, who died in the second year of their marriage, leaving one son, Thomas, afterwards earl of Exeter. In the same year, having successfully contended in an argument on the supremacy of the Pope and the Catholic Faith with two priests, chaplains of O'Neil the Irish chief, he was at the king's desire brought into his presence. Conceiving a favourable opinion of Cecil's abilities, the king, in order to secure his services, conferred upon him the reversion of the office of custos brevium in the Common Pleas; an office of considerable emolument, and which fell into his possession about five years afterwards. Shortly after

the accession of Edward VI. Cecil married Mildred, daughter of Sir Anthony Cook, the director of the king's studies; which connexion, together with his acknowledged high talents and habits of application, and his known attachment to the principles of the Reformation, procured him the friendship of the lord protector, to whose service he had already been recommended by the Cheke family. In 1544 the lord protector appointed him his secretary of requests, an office not only of distinction but of great trust. In the same year he accompanied the lord protector in the Scotch expedition, and was present at the battle of Musselburgh. Cecil quickly acquired the esteem and confidence of the young king, and in the year 1548 was appointed secretary of state.

On the fall of the lord protector, Cecil was committed to the Tower, but was discharged after an imprisonment of three months; and in October, 1550, was by the duke of Northumberland restored to his office, knighted, and sworn of the privy council. It does not appear that he was in any way privy to the fall of his early patron the lord protector; but the extreme caution of his subsequent behaviour to his fallen friend borders closely on ingratitude.

Soon after his re-appointment as secretary of state, Cecil effected several important measures. The abolition of the exclusive privileges of the merchants of the Staple yard seems to have sprung from that large and enlightened policy which distinguished his whole career. He further proposed to abolish the staple or regular market for the wool and chief productions of England, then existing at Antwerp, and to open two free ports in England, one at Southampton, the other at Hull; and from the then low state of commercial knowledge, and the perplexities arising from foreign intrigues, the plan was not accomplished.

Cecil took no part in Northumberland's designs for altering the succession to the throne on the death of Edward VI., though he affixed his name to the instrument of settlement as witness to the king's signature, at his earnest request. On Northumberland's march into Cambridgeshire Cecil joined Mary, who had already been declared queen, and by whom he was graciously received. Under the new reign he gave up his employments because he would not change his religion, but he did not join in the cabals of either party. He cultivated the friendship of many of Mary's ministers, and became attached to the party of Cardinal Pole, who, in opposition to Gardiner, advised moderation and mildness in matters of religion.

Being chosen in 1555 one of the members for his native county, he distinguished himself by his opposition to the measures of the Catholic party. The passage of the bill for confiscating the estates of such as had left the kingdom on the score of religion is mainly attributed to him. In consequence of his conduct on this occasion he was summoned before the privy council, but he made so satisfactory a defence that he escaped committal to the Tower; a fate which befel those who were summoned with him. He, however, continued in that and the next parliament to advocate the cause of the persecuted Protestants. Foreseeing that Mary could not long survive, Cecil opened a private correspondence with the Princess Elizabeth, and enabled her by his communications and counsel to avoid the snares of the vindictive and suspicious Mary. On the very day of Elizabeth's accession he presented to her a paper setting forth twelve affairs which required immediate dispatch; which particulars, it is remarkable, formed the basis of his chief measures throughout his long administration. He was the first person sworn of the privy council in the new reign, and was forthwith appointed secretary of state. From this time until the close of his life Cecil directed the affairs of England. A full account of his life would be the history of the reign of Elizabeth. Vain, mean, and capricious as the queen was, her sound judgment enabled her to see the true value of Cecil, and induced her on many occasions to yield to his cool and dispassionate reasonings. In 1571 Cecil was created Baron Burleigh, in 1572 he received the order of the Garter, and in the same year succeeded the Marquis of Winchester as lord high treasurer; in which office he continued till his death. These honours may seem but an inadequate reward for Cecil's services, but the pension in the reign of Elizabeth was a mark of the highest favour, and a token of real merit. Except in the instance of Leicester, no example perhaps occurs in that reign of a title acquired without desert. It is impossible within the limits of this article to

notice given minister, principal measures promoted by this great branch of his policy, whether in relation to religion then formed so material a part of European affairs, the internal policy, by fixed and well grounded principles, and administration appears to have been produced by the temporary expediency only, but to have formed a consistent and well considered plan. Caution and intrigue were necessary in an age when negotiation was a system of duplicity. Few ministers have been exposed to more unanimous attacks than Lord Burleigh. The favourites of the queen were at all times opposed to his judicious and economical policy. The frequent plots occasioned by the rancorous excitement of religious feeling—the disputes fostered by the unsettled state of the succession—the unflinching feeling excited and produced by Mary queen of Scotland and her persecutions—and the capricious and hypocritical conduct of Elizabeth, herself secretly approving and publicly blaming her minister, and holding him up to screen herself from public disapprobation—all conducted to embarrass his plans and confound his operations. But the accurate information which Lord Burleigh at all times obtained, his vigilance, his unceasing application, and unimpeachable integrity, enabled him to overcome the difficulties which surrounded him, and to the end of his career to retain the favour of the queen and the respect and affection of her subjects. It is worthy of observation, that those parts of his conduct which have been characterised as unfeeling and selfish, have generally received the approbation of posterity; and that, with all the advantage we possess from the knowledge of the effects of his measures, that they were the most judicious that could have been taken for the preservation of the peace and welfare of his country, and the establishment of the reformed religion. He was distinguished for self-command and moderation. It was observed that he never spoke harshly of his enemies, nor embraced any opportunity of revenge; and as he was no less on his guard to avoid every undue bias from affection, it became a general remark that he was a better enemy than friend. 'I entertain,' he said, 'malice against no individual whatever; and I thank God that I never retired to rest out of charity with any man.'

In common with most other great public men, he possessed discernment in discovering men of peculiar talents for business. 'He seemed resolved that England should be distinguished above all nations for the integrity of her judges, the piety of her divines, and the sagacity of her ambassadors.' He encouraged open discussion, as tending to the discovery of truth. He was strictly and scrupulously impartial; magnanimous in his several establishments; and liberal to his officers and dependents. He gave largely in charity, and increased his private fortune without borrowing from the coffers of the state, as before his time was the common custom with those who had the power, and without tarnishing his fame by any public or private extortion, as appeared at his death, when the queen instituted a rigorous inquiry into his affairs. In private he was cheerful, affable, and facetious; abstemious in his own diet, he enjoyed the cheerful relaxation at his table with his family and friends. 'Indeed,' says Fuller, 'no man was more pleasant and merry at meals, and he had a pretty wit-rack in himself to make the dumb to speak and to draw speech out of the most silent and sullen guest at his table, to show his disposition in any point he should propound.'

Books and the superintendence of his garden at Theobald's formed his chief amusement in his few hours of leisure. His mind was strongly tinctured with piety. His faith had been endeared to him by persecution; his piety was exalted by the sacrifice of his interests to religion; he was accustomed to say, 'I will trust no man if he be not of sound religion, for he that is false to God can never be true to man.'

In 1589 he lost his wife Mildred, his affectionate companion for 43 years. The despondency produced by this calamity, the increasing infirmities of age, and successive attacks of the gout, rendered more severe by a weakness which had been caused by his sedentary habits, interrupted the unruffled calmness of his temper: he became subject to bursts of peevishness, but on such occasions he immediately endeavoured to make reparation for the pain which he had caused. He died, says his contemporary biographer, on the 4th August, 1598, in the 78th

year of his age, having held the station of prime minister of England for upwards of half a century. His death-bed was surrounded by friends whom he esteemed, by children for whose future welfare he had provided, by servants devoted to him from a long interchange of good offices, and he expired with the utmost serenity and composure. He had, by his first wife, Robert, created earl of Salisbury; Anne, married to Edward Vere, seventeenth earl of Oxford; and Elizabeth, married to William, eldest son of Lord Wentworth, of whom the first-named only survived him.

(Macdarmid's *British Statesmen*; *Biog. Brit.*; Camden's *Annals*; Fuller's *Holy State*.)

CECIL, ROBERT, EARL OF SALISBURY, son of Lord Burleigh, by his second wife Mildred, was born about 1550. He was of a weakly constitution and deformed in his person, upon which account he was not sent to school; he afterwards went to St. John's College, Cambridge. He was knighted by Queen Elizabeth, who sent him as assistant to the earl of Derby, the English ambassador in France. On his return, in 1596, he was appointed second secretary of state; and on the death of Sir Francis Walsingham, became principal secretary, in which office he continued till his death. He was appointed to various offices of trust, by Elizabeth; and on the decease of his father, succeeded him as prime minister. He privately corresponded with James I., and, on his accession, was confirmed in his office. In 1603, he was created baron of Essenden; in 1604, Viscount Cranbourne; and in 1605, earl of Salisbury; his elder brother Thomas being created earl of Exeter on the evening of the same day. He was also elected chancellor of the university of Cambridge, and installed a knight of the garter in the same year. In 1608, on the death of the earl of Dorset, he succeeded to the office of lord high treasurer, in which capacity he effected great reformation in the Exchequer. He was unquestionably the ablest minister of his time, and appears to have repressed the increasing encroachments of the crown to the utmost of his power. He exposed himself to considerable odium, and made many enemies as the chief promoter of the disgrace and fall of the earl of Essex, and afterwards of Sir W. Raleigh. Indeed with regard to Raleigh, subsequent inquirers have charged him with criminal and disgraceful conduct; but he was never accused of pecuniary corruption or dishonesty. He married Elizabeth, daughter of William Brooke, Lord Cobham, by whom he had a daughter and a son. Worn out with business, he died at Marlborough, on his road from Bath, where he had been for the recovery of his health, on the 24th of May, 1612, observing to Sir Walter Cope—'Ease and pleasure quake to hear of death; but my life, full of cares and miseries, desireth to be dissolved.'

He wrote 'A Treatise concerning the State and Dignity of a Secretary of State, with the Care and Peril thereof,' 'A Treatise against the Papists,' and 'Notes on Sir John Dee's Discourse about the Reformation of the Calendar.' (*Biog. Brit.*; Peck's *Desiderata Curiosa*.)

CECILIANI (Zoology), the name of a genus of naked serpents (*Cecilie* of the French), which some naturalists have considered as belonging rather to the Batrachians, but which Cuvier, following Linnæus, places in his third and last family (*Les Serpents Nus*) of the Ophidians, observing that those who placed it among the Batrachians did so without knowing whether the form underwent metamorphosis or not.

This genus was named *Cecilia* by Linnæus, from the supposed blindness of the species. The eyes, in fact, are exceedingly small, and nearly hidden under the skin. Cuvier observes that in some species these organs are wanting altogether, and the following is his description of the genus. The skin is smooth, viscid, and striated with annular folds. It would appear altogether naked, but on dissection scales well formed are found in its thickness; but these scales are delicate and disposed regularly in many transverse rows between the wrinkles of the skin, as Cuvier himself saw with certainty in *Cecilia glutinosa*, *Cecilia albiventris*, and other species. The head is depressed. The vent is round, and very near the end of the body. The ribs are too short to circumvent the trunk, and the articulation of the bodies of the vertebrae is effected by facets with hollow cones, the depression in which is filled with a gelatinous cartilage, as in the fishes and in some of the Batrachians. Their skull is united to the first vertebra by two tubercles, as in the Batrachians; a mode of union approached by the

Amphisbænæ only among serpents. Their maxillary bones cover the orbit, which is only pierced in the form of a small hole, and the temporal bones cover the temporal fossa, so that the head when examined from above presents only a continuous bony shield. Their hyoides, composed of three pair of arches, may have led to the supposition that in early youth the bones supported the tongue. The maxillary and palatal teeth are arranged on two concentric lines, as in the Protei, but are often sharp and curved backwards as in the true serpents. The opening of the nostrils is at the back of the palate, and the lower jaw has no moveable pedicle, while the tympanic bone is dovetailed (*enchassé*) with the other bones into the shield of the skull. The only *ossiculum auditus*, or auditory bone, is a small plate upon the *fenestra ovalis*, as is the case with the salamanders.

[Skull of *Cæcilia*.]

The auricle of the heart in these animals is not divided sufficiently deep to be regarded as double, but the second lung is as small as it usually is in the other serpents. The liver is divided into a great number of transverse leaves (*fillets*). In their intestines Cuvier states that there is to be found a quantity of vegetable matters, vegetable earth (*humus*), and sand.

Geographical Distribution.—Warm climates. *Cæcilia annulata*, for example, is an inhabitant of Brazil (Spix), and *Cæcilia glutinosa* of Ceylon. Daudin indeed says that the last named species is American: but Cuvier avers, notwithstanding Daudin's assertion, that M. Lechevalier brought it to France from Ceylon. He adds however that *Cæcilia bivittata* (*bivittata*), Cuv., a species nearly approaching *C. glutinosa*, is an inhabitant of America.

[*Cæcilia bivittata*.]

In treating of *Cæcilia*, Dr. Mayer expresses his dissent from all naturalists who have hitherto written on the genus, with respect to what have been considered its most essential characters. The wrinkles on the skin, for instance,

which have been so much insisted upon, he in himself very unimportant. The skin is mainly due to the contraction of the skin, and spirit in which the animals are preserved. Dr. Mayer enters into a very minute account of the manner in which its outer covering is formed, which clearly proves that this also is a mistaken notion (*Zoological Journal*, vol. ii, p. 254).

The *Cecilians*, in the system of W. form the suborder, and comprehend only three genera, *Siphonops* (Wagler), *Cæcilia* (Linnaeus), and *Amphiuma* (Wagler), and are referred to a family termed *Hedro*, because the tongue adheres throughout its length to the lower jaw. The following are the characters of the family: without a tail, naked; os carré (*tympani*) soldered to the skull; two occipital condyles; orifice of the ear rounded, and situated at the extremity of the body.

CELANDINE. [CHELIDONIUM.]

CELANO, a beautiful lake (the *Ficinus* of the Romans) and also a town in the province of Abruzzo Ultra, or the further Abruzzo, in the kingdom of Naples, in Italy. The and the tunnel made by the Emperor Claudius to off the superabundant water of the lake, which is liable to great and sudden rises, are described under the general head of Abruzzo. Since that article was written, the ancient tunnel, which has been blocked up and altogether useless for many centuries, has been so far rendered available as to carry off a constant though not a large stream of water through a mountain into the Liris, or Garigliano, which runs in a deep and narrow valley at the distance of three miles from the lake.

It is supposed that this issue of water will suffice to keep the lake to its present level; but much greater plans are proposed—namely, to enlarge and extend the tunnel, to correct some hydraulic errors committed by the Romans, and make the subterraneous passage serve to reduce the lake to the limits which it occupied in 1745, since which year its encroachments have swallowed up more than 10,000 acres of the best land in the province. The important repairs already made have been made at the expense of the king of Naples, and under the direction of Signors Alan de Riera and Luigi Giura. Considered merely as a remnant of antiquity, the tunnel, or, as it is called in the country, the emissary (*emissario*) of Claudius, is an exceedingly interesting object. At the opening of it near the lake, it is about thirty feet high and twenty-eight feet broad; but it appears that it contracts considerably as it advances through the mountain. Its whole length is three miles. It is in part cut through a solid calcareous rock, and in part through a chalky earth that has little tenacity. Wherever the latter substance occurs it is supported by masonry of admirable workmanship. To admit light and air the Romans sunk shafts from above, through the body of the mountain, down to the level of the passage. The entrance to this tunnel is about a mile and a half to the south of the town of Avezzano.

The town of Celano, a thriving place, with a population of about 3000 souls, is beautifully situated on a hill, about a mile and a half from the northern shore of the lake. The name occurs very frequently in the history of the middle ages, when the counts of Celano were among the most powerful feudal lords in Southern Italy. Besides Avezzano, which is equal or rather superior in importance to Celano, there are Luco, Trasacco, Ortucchio, and many other small towns and villages scattered round the shores of the lake, or on the sides of the mountains above them.

CELASTRACEÆ, a natural order of polypetalous exogens, consisting of shrubby trees principally found in temperate latitudes, and abounding in either the colder or the hotter parts of the world. They have simple alternate or opposite leaves, a small number of perigynous stamens inserted into a fleshy disk, and alternate with the petals, a superior syncarpous ovary immersed in the fleshy disk, and a superior capsular or baccate fruit, with a small number of ascending seeds. The order is not of much economical importance. A high degree of acidity is said to have been detected in some of the species. *Eucalyptus*, or the gum-tree, the wood of which is used for medicinal purposes, is the commonest European form of the order.

[*Echinymus atropurpureus*.]

1. A front view of the flower. 2. The same from below, showing the ovary.
 3. A view of the disk, with the stamens. 4. A stem. 5. A ripe fruit.
 6. A cross section of the fruit. 7. A longitudinal section of the fruit.
 8. A stamen. 9. A pistil.

CELEBES, a large island of singular shape in the Eastern Seas, lying between 2° N. lat. and 6° S. lat., and extending from 119° to 125° E. long. The extreme length of the island from N. to S. is near 500 miles. The coast on the S. and E. is so deeply indented by three bays as to give to the whole island the appearance of four large peninsulas. The area of Celebes is supposed to be about 70,000 square miles, but there is a very considerable discrepancy in estimates that have been made.

This island is separated from Borneo by the Strait of Macassar, the eastern boundary of which is formed by the western coast of Celebes. This strait, which is 300 miles long from N. to S., is about 120 miles broad, except at its northern termination, where it is contracted to half that breadth by Konnekoorgan Point on the eastern coast of Borneo. The three bays or gulfs of Celebes are Sewa or Burgess Bay, Tolo Bay, and Tomini or Gorong-talu Bay. Sewa Bay, sometimes also called the Bay of Boni, is entered from the S.; Tolo Bay is open to the S. and the E.; and Tomini Bay, which is towards the northern part of the island, is entered from the E. The gulf, which is formed by the northern division or limb of Celebes, by the north-eastern coast of Borneo, by the Soo-loo Archipelago, and the island of Mindanao, is called the Sea of Celebes.

The island is divided into several small independent states, of which Count Hogendorp has described thirteen. 1. The districts of Menado and Gorontalo are in the northern part of the island. The first belongs in full sovereignty to the Dutch government, and the second is under the nominal sway of a sultan who is in a state of vassalage to the Dutch. These districts produce coffee, rice, and gold; and excellent cordage is made from the fibrous product of a tree, the *Goumouti*. 2nd. Mandhar is ruled among seven chiefs, between whom an intimate alliance is kept up. 3rd. The territory of the prince of Sidereng. 4th. The kingdom of Tanete, on the west side of the island. 5th. The states of Luwu, Wajo, and Soping, to the north of the gulf of Boni; the first, on the east side of the island, is one of the greatest sovereignties, and occupies nearly a fourth part of the territory of Celebes. Its internal condition of this kingdom is but little known, and no statements have been offered concerning its population. Wajo and Soping together contain about 15,000 souls. 6th. The kingdom of

Boni is populous but poor. An efficient report, made in 1824 by the Dutch residents, stated that the king of Boni had within his dominions 40,000 men capable of bearing arms, and that the whole population amounted to 200,000. 7th. The dominions of the king of Macassar, having a population of 25,000 souls. 8th. Tello, governed by a queen, a vassal of the king of Boni. 9th. The districts of Maros, with a population of 100,000 souls, divided into regencies under the Dutch government. 10th. The states of Touraito, divided among three chiefs who were formerly vassals of Boni, but who made themselves independent of that power in 1814, and placed themselves under the protection of the Europeans in the island. 11th. The districts of Boulicomba and Bonthain, with 25,000 souls, under the Dutch government. 12th. Districts, also under the Dutch, denominated the Southern Districts, divided into twelve regencies, and containing a population of 75,000. And 13th. the small district in which Fort Rotterdam, the chief seat of the Dutch government, is situated: the population of this district is about 15,000 souls.

The native sovereignties here mentioned are all subdivided under numerous feudatory chiefs.

The centre of the island, the nucleus of the four peninsulas, is a mountainous tract from which four arms branch out into the four peninsulas respectively, and terminate in promontories.

The island contains three considerable rivers. The largest, the Churana, rises in the Wajo country, crosses the kingdom of Boni, and discharges itself by several mouths into the gulf of Sewa. This river is navigable to a considerable distance by ships of 300 or 400 tons burthen; the native proas ascend much farther to a fresh-water lake. The river Boli has a bar at its mouth with three fathoms water: it discharges itself on the north coast after a long and winding course. The third river has its mouth on the west coast to the south of Macassar. Besides these rivers, there are numerous small streams, especially on the south coast, which are navigable for a few miles by the vessels of the country.

The island is for the most part fertile, but agriculture is generally in a very backward condition, the inhabitants being much attached to ancient customs and superstitions, and their tastes leading them to prefer navigation, fishing, and commercial pursuits to the more quiet employments of farming. The Bugis, or inhabitants of Boni, are excellent seamen: their proas visit every part of the Indian archipelago, and even go as far as the Gulf of Carpentaria for the purpose of taking the tripang (*biche de mer*), which is a profitable article of trade with China. These proas, which the natives call *paduakans*, are never larger than 50 tons burthen. Their bows are lowered or cut down so as to be often under water, while a high bulk-head is raised at the stern to keep off the sea. They have only a tripod mast, made of three stout bamboos, two rising from the sides and one from the bow, and lashed together at the top; this mast carries a high pointed sail.

The principal productions of the island are rice, sugar, and cassava, but not raised in sufficient quantity for the consumption of the inhabitants, and every year rice is imported from Java. Cotton and tobacco are raised in small quantities. In the district of Luwu, are iron mines, yielding metal of an excellent quality. The island also contains gold mines, which have never been regularly wrought. The whole coast abounds with fish, and the number of turtle taken is so considerable that 50,000 pounds weight of tortoise-shell is annually shipped. The women of the country weave cotton cloths of common quality for domestic use, and of a finer kind, which are exported to Java and other of the Indian islands.

The Macassar horses are larger, stronger, and of higher courage than those of Java, to which island many hundreds of them are annually taken for sale.

The population of Celebes is composed of several distinct races, speaking different languages. The Bugis are the most numerous, and include a large proportion of the tribes in the southern parts of the island. The Macassar language is spoken by several tribes who inhabit the southern and western limb of the island. The Mandhar language prevails in the central part of the island, and towards the western coast, and the Mandos inhabit the north-eastern limb. The centre of the island towards the north is inhabited by the *Togias* or *Horaforas*, who are supposed to be the aborigines of Celebes. Of all these people the Bugis are considered

to be the first in enterprise and intelligence; they engross nearly all the carrying trade of the Indian archipelago, the trading of other tribes being almost entirely confined to coasting voyages. The Bugis are esteemed to be very fair dealers, and they often embark in extensive speculations. The Portuguese formed a settlement at Macassar in the year 1602, and it was not until after that time that the Mohammedan religion was introduced; it is not known in what their religious faith or ceremonies then consisted. In 1603, the rajah of Macassar, with the whole of his subjects, made a public renunciation of their ancient faith, and embraced Mohammedanism, after which they immediately compelled their weaker neighbours to follow their example.

It appears from the early records of the English East India Company, that they must have established a factory at Macassar about the beginning of the 17th century, which was broken up through the contrivances of the Dutch, who in 1667 concluded with the rajah a treaty, afterwards known as the Boni treaty, by one article of which he engaged to expel both the Portuguese and English, and not to admit the subjects of any other European nation, or ambassadors from such, to enter his dominions.

The principal establishment of the Dutch in Celebes is at Macassar, on the west coast, and near the southern extremity of the island, on the spot where formerly stood the native town of Macassar, known also under the name of *Oudjong Pandang*. The European inhabitants at present amount to about 800 souls, exclusive of the garrison stationed in Fort Rotterdam. The roadstead affords good and safe anchorage, being protected from the N. to the S.W. by two islands called Great and Little Ly-Ly. The Dutch governor of Macassar has under his orders five resident, who are severally stationed in the North, the South, and the Bontain districts, the island of Sumbawa, and the island of Salayar, for the purpose of administering justice. In 1811 the Dutch authority in Celebes was transferred by conquest to the English, who, on the return of peace, quitted the island, in which the Dutch again established themselves in 1816.

(Stavorinus's *Voyages*; Forrest's *Voyage*; Crawford's *Indian Archipelago*; Count Hogendorp's *Coup d'Œil sur l'île de Java*, &c.; *Report of Committee of House of Lords on the Affairs of India*, 1830.)

CELERY, or **APIUM GRAVEOLENS**, is a wild umbelliferous plant by no means uncommon in the marshes of England, especially near the sea in the Isle of Thanet it is abundant. In its native station it has the character of being a poisonous plant, but transplanted to a garden it becomes an agreeable and wholesome vegetable. This is in conformity with the general properties of umbelliferous plants, in which two principles, the aromatic and the narcotic, exist, and which are food or poison, as the one or the other predominates. The narcotic is generated abundantly in moist places, and the aromatic principally in dry situations; and hence plants that are dangerous while growing in marshes become wholesome when transferred to dry places. This appears to be one cause of the difference between the wild and the cultivated celery; another is that the latter is blanched before it is brought to table, and thus the secretion of the deleterious principles is prevented.

Of garden celery there are many varieties, the best of which for salad is the Turkish, and for stewing, the Celeriac or the turnip-rooted sort. For soups, the 'seeds' may be employed with as much advantage as the stems or leaves.

Celery is raised in beds, from seed sown from the end of March to the beginning of May, and requires a light, rich, well-drained soil. When the plants in the seed-bed are about two or three inches high, they are pricked out into another bed, where they remain till they are six or seven inches high; they are then transferred to trenches, in which they are placed in a row, and finally left. As they advance in size, they are gradually and carefully earthed up, till at last the whole length of the stem under ground is sometimes as much as four feet. The goodness of celery depends essentially upon its growing rapidly, being kept well drained from moisture, and having a solid stalk to its leaves. Celeriac is not earthed up, but is grown upon the surface of the ground, and kept free from weeds and preserved from the emission of strong lateral roots by frequent hoeing. (See *Horticultural Transactions*, vol. iii.)

CELESTINE, or **CELESTINUS I.**, bishop of Rome, succeeded Boniface I. in 422, was engaged in disputes first with the African bishops on matters of discipline and eccle-

siastical jurisdiction, afterwards with the British in Britain, and lastly with the Nestorians in the East. The installation of Cyril, bishop of Alexandria, a Nestorian. Celestinus died in 431, and was succeeded by Sixtus III.

CELESTINE II., a Tuscan, succeeded Innocent III. in 1143, and died after a five months' pontificate in 1144.

CELESTINE III. succeeded Clement III. in 1191, crowned the emperor Henry VI., excommunicated Leopold, duke of Austria, and Alonso IX., king of Leon, and died in 1198.

CELESTINE IV., a Milanese, was elected to succeed Gregory IX. in 1241, but died a few days after his election.

CELESTINE V., Pietro da Morrone, was elected in 1294; a few months after he resigned his office, and was succeeded by Boniface VIII., who confined him in the castle of Fumone, where he died, it is said, of starvation. [BONIFACE VIII.]

CELESTINES, ORDER OF, a monastic order, instituted about 1254 by Pietro da Morrone, afterwards Pope Celestine V., from whom they took the name of Celestines. Their first convent was at Morrone, in the Apennines of Abruzzo. It was a reform of the order of St. Bernard. Urban IV. approved its institution, and Gregory X. granted many privileges, with an exemption from payment of tithes, &c. It became a very rich order, both in Italy and France. In 1770, in consequence of an order from Louis XV., the Celestines of France held a capitulum, or general assembly, from the various houses they had in that country, to consider of several reforms in their discipline and economy, which was insisted upon by the king. These however they refused to adopt, and preferred the secularization or suppression of their order, which was ultimately effected by Pius VI. in 1776-8. Their property was taken possession of by royal commissioners, a suitable pension being allowed to each monk. Some years after, Ferdinand IV. of Naples suppressed the Celestine convents in his kingdom. [BONIFACE VIII.]

CELLA. [TEMPLE.]

CELLARIA. [CELLARIEA.]

CELLARIEA, or **CELLARIADÆ** (Zoology), the second family, according to De Blainville's arrangement, here given, of the sub-class *Polyparia Membranacea*.

Animals hyaliform, provided with very delicate tentacula, separated, distinct, contained in oval flattened membranous cellules, with a bilateral, nonterminal opening forming by their lateral junction, on one or two tiers or stages, a sort of retaceous or membranous, limited, disciform and fixed polyparium.

Ovaries arternal?

The *Cellariæ* (Polyparia membranacea cellariæ), for such is De Blainville's term for the family, are, as he observes, sufficiently defined, inasmuch as the cellules, which are more or less polygonal, with a binary opening, are always disposed in laminae or plates, applied either to foreign bodies, or against another similar plate, or around a supposed axis, as in the last genera of the family (*Polyparia operculifera*) which precedes it, but they are not provided with an operculum. De Blainville remarks on the possibility of a division of the so-called multilocular shells belonging to this family, and being composed in fact of young *cellariæ*.

GENERA.

1. *Lunulites* (fossil).

Animals unknown, contained in cellules with a superior opening, disposed upon a single tier or stage in concentric circles and diverging rays, so as to form a retaceous, sufficiently regular, orbicular polyparium, convex above, concave below, and marked with depressed striae radiating from the centre to the circumference.

Example. *Lunulites radiata*. Locality, Grignon, &c.

Lamarck established this genus for two small fossil polyparia. Lamouroux considered the second species (*Lunulites arcuolata*), sufficiently different to warrant his establishing on it a distinct genus, named by him *Cupularia*. *Lunulites crassa* occurs in the cretaceous group at Maestricht, Tours, and in the belemnite limestone of Normandy. The following cut of DeFrance's *Lunulite en parasol* illustrates the juxtaposition and form of the cells.

[DeFrance's *Lunulite en parasol*.]

a, a portion magnified; b, natural size; c, three cells highly magnified.

2. *Electra*.

Animals unknown, contained in membranous, vertical, bell-shaped cellules, ciliated on the edges and shut by a diaphragmatic membrane, with a very small and semilunar opening, and verticillated either round some foreign body or under the form of spiciform branches.

Example. *Electra verticillata*.

[*Electra verticillata*.]

a, natural size; b, magnified.

This is the *Flustra verticillata* of Gmelin, *Sertularia verticillata* of Esper; and the genus, which was separated by Lamouroux, does not differ from the other *Flustra* except in the verticillated disposition of its cellules round the bodies which those cellules incrust, and, as De Blainville observes, scarcely deserves to be distinguished from *Flustra pilosa*, whose cellules are occasionally somewhat verticillated.

3. *Flustra*.

Animals hydriform, provided with simple tentacula, contained in complete, distinct, very flat cells, formed by a thick border, encircling a membranous part, in which the subterminal and transverse opening is pierced, disposed regularly and in the form of a quincunx, so as to produce a membranous flexible crust or polyparium, fixed by radical fibrils.

a. Encrusting species.

Example. *Flustra dentata*. Locality, Northern Seas.

[*Flustra dentata* magnified.]

β. Frondescent species, with two tiers or stages of cells.

Example. *Flustra foliacea*.

[*Flustra foliacea*.]

a, natural size; b, some of the cells magnified.

γ. Frondescent species, with a single tier of cells.
Example. *Flustra caribaea*. Locality, Seas of Scotland, &c.

[*Flustra caribaea*.]

a, a portion, natural size; b, a portion magnified.

Mr. Dalyell, in his interesting paper entitled 'Fugher Illustrations of the Propagation of Scottish Zoophytes' (*Edinburgh New Philosophical Journal*, April-July, 1836), gives the following account of the propagation of the *Flustra*. Speaking of *alcyonium*, he says, 'We find it consist of a compact gelatinous or fleshy matter, studded with innumerable cells sunk in its substance, which are inhabited by vivacious hydræ. Different species or varieties occur in the Scottish seas, especially the *gelatinosum*, and a thin green flattened palmate kind, which has perhaps escaped the notice of naturalists hitherto. A white, opaque, ovoidal or nearly circular, flattened corpusculum, previously invisible, issues from the fleshy part of these products, whence it seems to be elicited, particularly by the influence of light. On removal of a small specimen, that had already afforded many, from a dark situation to a moderate degree of light, at least 150 quitted their recesses within an hour. These beings are endowed with much greater activity than the corpuscula of the actinia; their courses are alike diversified; they swim through the water in all directions, regularly and irregularly, ascending to the surface or descending to the bottom, pursuing a straight line, describing an orbit, or tumbling about among the neighbouring substances. Meanwhile, as if of soft consistence, their form alters, and the action of the cilia environing the body is alternately depressed and relaxed. At length, having become stationary, a margin diffuses around the body, and supervening transparency of the centre soon exposes an inanimate hydra within, which in nine or eleven days is displayed perfect from its cell. The inner surface of each tentaculum is now clothed by a double row of stout dark cilia in rapid motion, but in opposite directions; for as those of one side strike upwards, those of the other strike downwards. Further diffusion of the basis adhering below forms additional compartments for other hydræ. The propagation of the *Flustra caribaea*, *foliacea*, and *truncata* ensues after a similar fashion. A ciliated corpusculum, spherical, ovoidal, or irregular, quits the leaf, pursues its course in the water, becomes stationary, adheres; and a nascent *Flustra* arises from the spot. Above ten thousand

such corpuscula have been produced by a moderate-sized specimen of the *Flustra foliacea*, tinging the bottom of a vessel yellow from their multitude, and vitiating the water by their decay.

The same author, in the 'Proceedings of the British Association' (Edinburgh, Sept. 5th, 1834), thus clearly and elaborately describes the organization of *Flustra carbasea*. 'The *Flustra carbasea* resembles a leaf divided into subordinate parts, one of the surfaces being studded with cells, and the other exhibiting elevations or convexities corresponding to their bottom, and the whole product is of a yellowish colour. Each cell, of a shuttle or slipper shape, level with the surface of the leaf, is inhabited by a vivacious polypus, exercising a percussive faculty both of the tentacula individually and of the whole head. Some of the cells are occupied occasionally by large, bright yellow, irregularly globular, solid ciliated animalcula, subsequently quitting them to swim heavily below. In several days they become motionless like the former, and die also without immediate decomposition. Next, there appears in just about the same spot below, occupied by the motionless animalculum, a yellow nucleus with a lighter diffusing margin. This in its further diffusion assumes a shuttle or slipper form, it becomes a single cell, which afterwards displays a polypus under the wonted figure and action. The adult *Flustra* is vertical, for the leaf is always erect; but here the new cell is horizontal. By a singular provision of nature, as only one side of the adult is cellular, the original cell is necessarily a root, sole, or foundation, to admit subsequent enlargement, which in such zoophytes is always from a single cell. One end of the cell next rises vertically, wherein a second cell, with its polypus, is soon displayed overhanging the first, and at right angles to the plane of its position.' (See also Professor Grant's Observations on the Polypes of this species in the 'Edinburgh New Philosophical Journal'.)

6. Frondescant species, with straight lobes and a single tier of cells.
Example, *Flustra avicularis*. Locality, European Seas. Se. Lord Bay, Sussex.

[*Flustra avicularis*.]
showing a spherical mass of the natural size

[*Flustra avicularis*.]
a, a specimen showing the root and branching form of the natural size; b, c, portions magnified: from Sowerby's 'British Miscellany', London, 1806

FOSSIL FLUSTRÆ.

These occur in the Baculite limestone of Normandy, the chalk of Sussex, the Great Oolite (Wilts), and in the Greywacke group (Gottland, Gloucestershire, Herefordshire, and the South of Ireland). De Blainville gives the following localities

α. Encrusting species.

In the calcaire tertiaire of Grignon, of Paris, and of the Pisanin, and in the calcaire des Grès et de Boulogne.

β. Frondescant species, with two tiers of cells.

In the limestone of Valognes and in the calcaire tertiaire of Grignon.

4. Elzerina.

Animals unknown, contained in sufficiently large oval elongated subhexagonal bordered cellules, having a membranous tympanum or drum, in which is pierced the sigmoid opening, forming by their quincunxial and circular arrangement the branches of a membranous, plant-like, nonarticulated, dichotomous, and fixed polyparium.

Example, *Elzerina Blainvillii*. Locality, the Seas of New Holland.

[*Elzerina Blainvillii*.]

a, natural size; b, a portion magnified.

De Blainville observes that this genus was established by Lamouroux for a polypier brought from the seas of Australasia by Péron and Lesueur, which De Blainville examined in Lamouroux's collection, and that he has been satisfied that it is a genus which can hardly be distinguished from the phyloid or plant-like *Flustra*—that it differs from them only in the union of the cellules, which form a circular quincunx, as in *Cellaria Subcornia*, and are still more soft and membranous.

Risso records two species of *Elzerina* in the Mediterranean, *E. venusta* and *E. mutabilis*; but De Blainville observes that, if it be true that their cellules are scattered, it is probable that those species do not belong to this genus.

5. Pherusa.

Animals unknown, contained in oval cellules, terminated by a sufficiently large projecting tubular opening, and disposed in oblique series on one of the surfaces only of a membranous or subgelatinous, lobated, frondescant, flabelliform, and fixed polyparium.

Example, *Pherusa tubulosa*.

[*Pherusa tubulosa*.]

a, upper side; b, lower side; c, a portion highly magnified.

This is the *Flustra tubulosa* of Ellis and Solander. De Blainville observes that Lamouroux is undoubtedly right in having withdrawn this form from the position in which Ellis and Solander had placed it, as De Blainville ascertained by the examination of a dried individual in a good state of preservation; but he thinks that *Pherusa* is intermediate between the *Flustra* and *Cellaria*.

6. Vincularia (fossil).

Animals unknown, contained in oval, subhexagonal, regular cellules, having a subterminal semilunar orifice, and applied and united longitudinally in many rows, so as to form a cretaceous brittle polyparium, in the form of a little wand.

Example, *Vincularia fragilis*. Locality of the genus at present known, the calcaire tertiaire of Westphalia.

De Blainville observes that this genus was established by De France, and that it has been adopted by Goldfuss under the denomination of *Glaucanoma*, a denomination which De Blainville rejects, remarking that Goldfuss regards it as approaching nearly to *Cellaria Subcornia*, and stating that the *Vincularia fragilis* which he (De Blainville) examined in De France's collection might well be nothing more than a true *Flustra*, which is found in the same beds with *V. fragilis*. De Blainville adds, in support of this opinion, that De France showed him a specimen which was composed of two or series instead of a single series only.

Cellaria.

Animals freeiform, pitcher-shaped, furnished with a circle of five cells, and an internal ovary, contained in regular hexagonal or oval cells, having a transverse or subtubular opening, disposed in circular quincunx on the surface of the cylindrical dichotomous articulations of a subcalcareous phytoid polyparium, fixed by a great number of horny radiciform tubes.

α. Species with hexagonal cellules, and with a transverse aperture. (Genus, *Salicornia* of Cuvier.)

Example. *Cellaria Salicornia*, *Cellularia Salicornia* of Pallas; *Tubularia fistulosa* of Linnæus. Locality, European seas.

[*Cellaria Salicornia*.]

α, natural size; β, a portion magnified; γ, a smaller portion still more highly magnified.

β. Species with oval cellules, and the aperture rounded and tubular.

Example. *Cellaria ceroides*, *Sertularia ceroides* of Gauch. Locality, Mediterranean and the Indian seas.

[*Cellaria Ceroides*.]

α, natural size; β, a portion of the lower part magnified.

De Blainville observes that this genus, established by Pallas under the name of *Cellularia*, has been successively simplified by Lamarek and by Lamouroux, who has established many genera at its expense. De Blainville further states that, before Delle Chiaje, no author who had described a species of a true cellaria was known; but that the Neapolitan observer had filled this gap by informing us in his Memoirs that the polypes of *Cellaria ceroides* bear a perfect resemblance to those of *Millipora (Myriapora) truncata*. Pallas made a curious observation relative to the rapid growth of *C. Salicornia*, for he found individuals an

inch and a half long upon the eggs of Squali, which were still far from the time when the young are excluded.

De Blainville, who studied the two living species of the seas of France, *C. Salicornia* and *C. ceroides*, but in the dried state, as he acknowledges, expresses his surprise that Linnæus should have bestowed the name of *Tubularia fistulosa* on *Cellaria Salicornia*, when there is nothing fistulous in its structure; and he adds, that it was probably that denomination which induced Schweigger to regard *Dactylopora* as an articulation of *Cellaria*.

De Blainville further states that no author makes mention of fossil *Cellaria*, unless we adopt the opinion of Schweigger, who pretends that the *Dactylopora* and the *Ovulites* are nothing but articulations of *Cellaria*, an opinion which appears to De Blainville to be inadmissible.

8. *Intricaria* (fossil).

Animals unknown, contained in hexagonal elongated cellules with elevated borders, and covering the entire surface of a calcareous polyparium sufficiently solid, rush like (juncifère) internally, composed of a considerable number of cylindrical branches irregularly anastomosed.

Example. *Intricaria Bajocensis*.

De Blainville observes that this genus was established by De France for a pretty fossil polypier found by M. de Gerville in the department of La Manche; and he states that on examining it in the collection of the first named of those naturalists, he was satisfied that it approaches very nearly to the *Cellaria*, and especially to *C. Salicornia* in the form of its cellules, while, however, it differs from it because it is not articulated, and because in all probability it did not adhere by radiciform fibrils. Lamouroux, he adds, thought it was a millipore.

9. *Canda*.

Animals unknown, contained in cellules which do not project but are resistant, suberectaceous, disposed on two alternate rows, and upon one surface only of the dichotomous branches, articulated, joined by transverse fibrils, and forming altogether a flabelliform, radicated, frondescent polyparium.

Example. *Canda arachnoidea*, Lamouroux; *Cellaria glifera*, Lamarek. Locality, sea of New Holland.

[*Canda Arachnoidea*.]

α, natural size; β, γ, portions magnified.

De Blainville observes that this genus was established by Lamouroux for a species of *Cellaria* brought by Peron and Lesueur from the Australian seas, and which he saw in Lamouroux's collection, which now forms part of the Museum of Caen. The assemblage of cells resemble the vertebral column of a fish. Upon one of the surfaces are two rows of alternate cells, separated by an angular crest. Upon the other surface may be seen the back of the cells, with tubular filaments which reach transversely from one branch to another, and are analogous to the radiciform or root like tubes. He adds that it would appear that these transverse fibrils are sometimes wanting, as in the variety noted by Lamarek.

10. *Caberea*.

Animals unknown, contained in very small cellules, disposed in quincunx on one of the surfaces only of the articulations (as if pinnated) of a calcareous, phytoid, dichotomous polyparium, bearing on its dorsal surface the continuation of the fistulous radicles by the aid of which it is fixed.

Example. *Caberea dichotoma*.

[*Caberea Dichotoma*.]

a, natural size; b, two cells magnified.

De Blainville states that he has examined the polypier on which Lamouroux established this genus, and observes that it is remarkable for the manner in which the cellules are piled obliquely on one surface only of the polyparium which they form, and on account of their being sustained by a fasciculus or bundle of radicleform tubes which occupy the dorsal surface. He adds, that the description and figure given by Lamouroux are inexact, the ridge which he represents and describes being nothing more than a disposition of the radicleform tubes; and that the pinnated *Caberea* of Lamouroux's collection is entirely different from *Caberea dichotoma*.

11. *Tricellaria*.

Animals hydriform, contained in cellules with an oval, terminal aperture with sessile borders, and disposed in three ranks, composing the articulations of a polyparium which is phytoïd, dichotomous, and fixed by radicleform fibrils.

Example. *Tricellaria tricythura*. Locality, seas of New Holland.

This is the *Crisia tricythura* of Lamouroux. The genus was established by Dr. Fleming, in his work on the British animals, from a species which differs from the *Crisia* of Lamouroux in the disposition of the cells.

12. *Acamarchis*.

Animals unknown, contained in united close-set and horny cellules, with a vesicle at the aperture, disposed in two lateral alternate ranks, and forming the articulations of a horny, phytoïd, dichotomous polyparium fixed by radicleform fibrils.

Example. *Acamarchis Neritina*. Locality, Mediterranean.

[*Acamarchis Neritina*.] a, natural size; b, lower portion magnified.

This genus was established by Lamouroux, but was not adopted by Lamarck, nor by Dr. Fleming, who, according to De Blainville, confounds it with *Bicellaria*. De Blainville states, however, that he has not examined either of the two species which constitute the genus *Acamarchis*, but remarks that it seems to him to differ too little from the true *Cellaria* to justify a separation.

13. *Bicellaria*.

Animals hydriform, furnished with eight simple tentacula, and contained in cellules which project but little or not at all, disposed upon two alternate ranks, and opening upon the same surface of the articulations of a cretaceous, phytoïd, dichotomous polyparium, which is fixed by radicleform filaments.

Example. *Bicellaria ciliata*, *Sertularia pilosa*. Locality, European seas.

This division of *Cellariadae*, *Crisia* of Lamouroux, *Cellaria* of Lamarck, was separated by Dr. Fleming, who gave it the denomination of *Cellularia*, a name preoccupied, as we have seen, by Pallas for the whole family. Instead of this name De Blainville proposes that here given, and observes that Savigny, in the plate which he has devoted to *Cellaria* in his great work on Egypt, has figured the solid part of four species, which, being composed of two ranks of cellules, should belong to this section.

14. *Crisia*.

Animals hydriform, but, as to the rest of their form, unknown, contained in cellules terminated by a projecting tubular aperture, and disposed upon two alternate ranks of the articulations of a phytoïd, dichotomous polyparium fixed by radicleform fibrils.

Example. *Crisia eburnea*, *Sertularia eburnea*, Linnæus; *Cellularia eburnea*, Pallas. Locality, European seas.

A genus established by Lamouroux, but considerably restricted by Dr. Fleming, who separated from it the species arranged under the genera *Tricellaria* and *Bicellaria*. De Blainville observes, that in a rigorous system of rational nomenclature it might be named *Tubicellaria*.

15. *Gemicellaria*.

Animals hydriform, contained in oval cellules, with an

[*Gemicellaria bursaria*.] a, natural size; b, a portion magnified.

oblique aperture, united two to two by the back, and forming thus the articulations of a phytoïd dichotomous poly-parium, adhering by radiiform fibrils.

Example. *Gemicellaria bursaria*. Locality, European seas.

This is the *Sertularia bursaria* of Linnaeus, *Cellularia bursaria* of Pallas, *Dynamena bursaria* of Lamouroux, and *Notamia bursaria* of Fleming.

The genus was proposed by Savigny in the plates of his great work on Egypt, under the name of *Gemicellaria*. Lamouroux established it with the denomination of *Loricaria*, an appellation changed by Dr. Fleming to that of *Notamia*, because *Loricaria* had already been appropriated to a genus of fishes. Dr. Fleming's name must however give way to Savigny's on the ground of priority.

De Blainville observes that it is in truth a genus which passes so nearly into the *Sertulariæ* that it scarcely deserves to be retained.

16. *Unicellaria*.

Animals unknown, contained in long cellules with a terminal aperture, forming one to one the articulations of a calcareous phytoïd polyparium, fixed by radiular fibrils.

a. Species with the cellules a little bent. (Genus, *Eucratea* of Lamouroux.)

Example. *Unicellaria chelata*, Ellis. *Sertularia loricata*, *Cellularia chelata*, Pallas. *Eucratea chelata*, Lamouroux; *Eucratea loricata*, Fleming. Locality, European seas.

[*Unicellaria chelata*.]

atural size; b, a portion highly magnified.

β. Species with cellules elongated into a cornet shape. (Genus, *Lafœa* of Lamouroux.)

Example. *Unicellaria Lafœi*, Lamouroux. Locality, seas of North America.

Lamouroux broke up this generic division into the genera *Eucratea* and *Lafœa*. De Blainville says that *Unicellaria* is easily characterized by the solitary disposition of its cellules, and that he had examined both *Eucratea* and *Lafœa* in Lamouroux's collection at Caen, and found the differences of too little value to warrant the separation. Lamarck, he adds, did not admit this genus, which Dr. Fleming does.

7. *Catenaria*, Savigny; *Catenicella*, De Blainville.

Animals unknown, contained in horny oval cellules, with an orifice not terminal but margined, springing one from the other, end to end, or transversely, and forming a sort of net-work or chain applied or adhering to the surface of marine bodies.

Example. *Catenaria Savignyi*.

De Blainville observes, that he found this genus indicated by Savigny in the zoological plates of the great French work on Egypt, under the name of *Catenaria*, a name

which, as he says, he has modified into *Catenicella*; but he gives no reason for this, and we see no occasion for altering the name given by the admirable observer who first pointed out the generic form. De Blainville wrote the character above given from an individual which he had found on marine productions from the Mediterranean, and observes, that it is evidently a genus very nearly approaching to *Unicellaria*, from which it differs only in the cellules adhering to the bodies to which they are applied, and in then not having a terminal aperture, adding, that it corresponds exactly with the genus named *Hypothoë* by Lamouroux.

18. *Menippea*.

Animals unknown, contained in oval cellules having a non-terminal aperture, disposed on one side only on a single rank, and rising dichotomously one from the other so as to form the articulations and branches of a subcalcereous, phytoïd, palmated polyparium, fixed by a great number of radiular fibrils.

Example. *Menippea hyalæa*, Lamouroux. Locality, Indian seas.

[*Menippea hyalæa*.]

a, natural size; b, c, cellules magnified.

This is one of the genera separated from the *Cellulariæ* by Lamouroux. Lamarck did not adopt it; but, as De Blainville observes, the form and disposition of the cellules are strongly defined. He considers it as approaching the *Catenariæ* in the form of its cells, but as differing widely from it in the manner of their forming the polyparium.

19. *Alecto* (fossil).

Animals unknown, contained in elongated tubular cellules, springing one from the other, often dichotomously, with an oval, subterminal, slightly projecting aperture. The cellules are always in a single rank, and form a sort of reticulation on the surface of marine bodies.

Example. *Alecto dichotoma*, Lamouroux. Locality, the upper Jurassic limestone of Caen.

A genus established by Lamouroux for a small fossil polyparium adhering and creeping as it were over fossil *terebratulæ*, and having the disposition of its cells a good deal like those of the *catenariæ*, which are also creepers. De Blainville observes, that the genus has also at first sight a certain number of relations to another fossil, viz. *Aulopora* of Goldfuss.

There is another and a pretty species (*Alecto ramea*, De Blainville), found by M. Huot on a belemnite, from the chalk of Meudon.

We have in this article followed the arrangement of M. de Blainville, one of the latest systematic writers (1834) on the subject; but it is more than probable that the observations now being made by M. Milne Edwards, will produce a system founded on an accurate investigation into the organization and anatomy of these animals and their congeners.

CELLARIUS, CRISTOPHER, born at Smalkald in 1638, studied mathematics and the Oriental languages at Jena. When thirty years of age he was made professor of philosophy and Oriental languages in the college of Weissenfels, and in 1673 was appointed rector of the college of Weimar. Frederic I., elector of Brandenburg, and first king of Prussia, having founded a new academy at Halle in Saxony, appointed Cellarius professor of history and rhetoric, an appointment which he held till 1707, when he died. The work by which he is most generally known is the 'Notitia Orbis Antiqui,' or 'Antient Geography,' first published at Jena, in a small 12mo., but considerably enlarged in subsequent editions. The best edition is that of Leipzig, 2 vols. 4to. 1731, after the author's death, with additions by Schwarz. This work, though it had a value in its day, is now almost useless. The other works of Cellarius are, 'Historia Medii

Ævi a temporibus Constantini Magni ad Constantinopolim a Turcis captam, Jena, 1698; '*Historia Nova, i. e. XVI. et XVII. Sæculorum cum initio XVIII.*' edited by Struve, 1720; '*De Latinitate Medice et Infimæ Ætatis, seu Anti-Barbarus*,' '*Coræ postiores de Barbaris ac Idiomatis Sermonis Latini*,' '*Orthographia Latina ex vetustis monumentis excerpta*,' 8vo. 1704, reprinted at Padua, 1739; '*Dissertatio Inauguralis Sistens Processum Juris Romani antiqui*,' 4to. 1698; '*Horæ Samaritanæ, sive Excerpta Pentateuchi Samaritanæ versionis, cum Latina interpretatione et annotationibus*,' followed by a Samaritan Grammar, 1682; '*Epistolæ Samaritanæ Sichemitarum ad Jobum Ludolfum*,' Samaritan and Latin, 1688; '*Origines et Successiones Comitum Wettinensium*,' 4to. 1697. Cellarius published editions of many of the classics, and he also edited '*B. Fabri Sorani Thesaurus Eruditionis Scholasticæ*,' with additions. His Academical Dissertations were published at Leipzig, 1712. His son Solomon, who was a physician, wrote '*De Originibus et Antiquitatibus Medicis*,' which some have inserted among his father's works. Andreas Cellarius, a relative of the former, wrote '*Regni Poloniæ Regionumque omnium ad id pertinentium novissima Descriptio*,' 12mo, Amsterdam, 1659. Balthazar Cellarius, a physician, left several medical works.

CELLASTRÆA. [MADRIPHYLLEA.]

CELLEPORA. [OPRUCULIFERA.]

CELLINI. RENVENUTO, was born in Florence, in the year 1500. His father was desirous that Benvenuto should be brought up to the profession of music, but he showed so decided a preference for the art of design that it was found impossible to keep him from his favourite pursuit, and he was eventually permitted to study sculpture: his first essays were made as a chaser and gold-worker. The elder Cellini however removed his son from the person with whom he was working, and made him apply closely to music till he was 15 years of age, when, without his father's consent, Benvenuto again established himself with a goldsmith called Marccone. In consequence of being engaged in an affray he was banished from Florence, and retired for a time to Siena. He afterwards went to Rome, where he met with great encouragement in his art. He returned however to his native city, and had every prospect of professional success, when, his ardent temper leading him into a quarrel, in which he severely wounded his antagonist, he found it necessary to disguise himself as a friar, and make his escape to Rome. It appears that he still cultivated music, for Pope Clement VII. was so well pleased at hearing him play at a concert that he took him into his service, in the double capacity of artist and musician.

The talents of Benvenuto were not confined to the arts of design and music: he distinguished himself in arms, and, according to his own account, was equally able as an engineer. When the Constable Duke of Bourbon laid siege to Rome, Cellini acted as a soldier, and he says it was he who killed the duke as he attempted to scale the city walls. He also signalized himself in the defence of the castle of St. Angelo; and the Prince of Orange, Cellini declares, was killed by a ball from a cannon which he pointed. Soon after this he left Rome, and made his peace with the magistrates of Florence. He next proceeded to Mantua, and, through the interest of his friend Julio Romano, the painter, was noticed favourably by the duke; but some indiscretion obliged him hastily to quit Mantua, and he again returned to Florence, where he became intimate with Michel Angelo Buonarrotti. At the pope's invitation Benvenuto again went to Rome, where he met with great encouragement, and, among other distinctions, received the appointment of engraver to the mint. In consequence however of the ill offices and calumny of one Pompeo of Milan, he lost his place, and was even arrested for refusing to give up a work he was engaged upon. A curious instance of Cellini's weakness occurs at this time, in the fact of his devoting himself to necromancy in the hope of recovering his mistress, who had withdrawn to Naples. Having quarrelled with one Benedetto, whom he wounded severely, and being denounced moreover as having killed one Tobia, of Milan, the pope issued orders to have him apprehended, and executed on the spot; but he contrived to make his escape, and succeeded in reaching Naples, where, as the promises of the necromancer had assured him, he met his mistress Angelica. He was kindly received by the viceroy, who wished to keep him in his service, but finding himself deceived by the fair Angelica, or her mother, Cellini quitted Naples and, under

Cardinal Ippolito de' Medici's protection, returned to Rome and obtained the pope's pardon. In 1534 his great patron Pope Clement VII. died; but Benvenuto's well known talents had now secured him many liberal and powerful friends. He says, in his life of himself, that on his return from St. Peter's, where he went to kiss the feet of the dead pontiff, he met Pompeo, who had falsely accused him of the death of Tobia of Milan, and that a quarrel ensued, which ended in his killing his adversary; but he adds, exultingly, he was protected from any evil consequences by the interest of his patrons, the Cardinals Cornaro and Medici; and Paul III., the new pope, desiring to have him in his service, gave him his pardon, and also reinstated him in his situation of engraver to the mint. About this time he unfortunately excited the enmity of Pier Luigi, the pope's natural son, who endeavoured to have him assassinated, but Cellini having intelligence of the design, made his escape to Florence, where the grand duke received him with every mark of kindness, and appointed him master of the mint. The pope however, anxious to have him in Rome, sent to invite him back, and Cellini again ventured to establish himself in that city: where he remained till he was recommended to try his native air as the only means of recovering from a severe illness. He returned however to the pope's service, and was appointed to carry the presents which were made by his holiness to the Emperor Charles V., on his visiting Rome. Cellini some time after this resolved to visit France, and, passing through Padua, visited Cardinal Bembo. On arriving in France he was most graciously received by Francis I., who offered to take him into his service, but being seized with illness he felt a dislike to the country, and returned to Rome by Ferrara, where he was honourably treated by the reigning duke. On arriving at Rome he was accused by his servant of having robbed the castle of St. Angelo, during the war of immense treasures, which led to his arrest and imprisonment. He was much persecuted on this occasion by Pier Luigi, the pope's son, who influenced his father to continue Benvenuto in prison: a resolution in which the pope was confirmed from pique at the French king's intercession in his favour. At length, with great ingenuity, and after considerable difficulties, he effected his escape, and proceeded to his kind friend, Cardinal Cornaro, who received and concealed him for some time; but his eminence being afterwards induced to deliver him up to the pope, he was committed a second time to prison, where he was treated with the greatest severity. He acquaints us, that after he had been confined some time he had a vision, which assured him of his speedy liberation.

At a banquet at which the pope entertained the cardinal of Ferrara, on his return from the Court of France, his eminence succeeded in procuring Cellini's pardon and enlargement, upon which he immediately finished a fine cup for the cardinal, and employed himself in other works; as a Venus and Cupid, Amphitrite and Tritons, and other performances.

He accompanied the cardinal back to Paris, where he met with a most gracious reception from the king, but being offered by the cardinal what he conceived too low a salary for his work, he left Paris abruptly, intending to make a pilgrimage to Jerusalem, and had even proceeded some way when he was overtaken by those sent in pursuit of him, and brought back to Francis I. The king settled a handsome salary upon him, and gave him an order to make various large statues for him in silver. But he had now the misfortune to offend Madame d'Estampes, the king's favourite, who did all in her power to disgust him, and to excite the king against him. With this view she encouraged Primaticcio, who was then at the Court of France, and set him up as a rival to Benvenuto: he was also engaged in a law-suit, but finding himself, as he says, much troubled and persecuted by the delays of the law, he had recourse to his sword, which intimidated his adversaries, and put an end to the suit. The Favourite still continuing to persecute him, he begged permission of the king to leave France. On his return to Florence, the Grand Duke Cosmo de' Medici received him with marks of attention, and gave him a studio to exercise his profession in, where he commenced his celebrated Persous; but being offended at some conduct of the grand duke's servants, he went to Venice, where he made the acquaintance of Titian, Sansovino, and other celebrated artists. Returning once more to Florence, he proceeded, though slowly, for want of means, with his Persous, which at last he finished.

He's declaring war against the inhabitants of

Sienna, Benvenuto was employed to repair the fortifications of Florence.

After his *Perseus* was exposed to public view, his success was so great that he undertook, in gratitude, a pilgrimage to Vallombrosa and Camaldoli. He was now employed upon many important works. The contest between him and Bandinelli for a statue in marble of Neptune is well known: it is said that the chagrin caused by the preference given to Cellini's design caused the death of the rival sculptor. Notwithstanding this, the duchess, who was Benvenuto's enemy, prevented his having the work, and it was given to Ammannati. He had soon after an opportunity of regaining the duchess's good opinion, by presenting to her and the duke a marble crucifix, a work mentioned and highly extolled by Vasari in his *Life of Cellini*. He was about this time invited by Catharine de' Medici to go to France, to superintend a monument to the memory of her husband, Henry II., but the grand duke desiring to retain him in his employment, the queen dowager relinquished her proposal, and Cellini did not again quit Italy. He died in Florence on the 13th of February, 1570, and was buried with great pomp in the church of the S. Annunziata.

The works of Benvenuto Cellini may be divided into two classes. The first, for which he is most celebrated, comprises his smaller productions in metal, the embossed decorations of shields, cups, salvers, ornamented sword and dagger hilts, clasps, medals, and coins, in which he showed great skill in composition, and excellence in the details of execution. The second includes his larger works, as a sculptor, and a reference to his bronze group of *Perseus*, with the head of Medusa, in the Piazza del Gran Duca, in Florence, will be sufficient to illustrate his merit in the higher walk of his art. He also executed some fine portraits.

It might be expected, from the constant employment Cellini had, wherever his uncertain and roving habits induced him to settle even for a short time, that a greater number of his highly-finished works would be found in collections. Their rarity must doubtless be accounted for by the temptation which the intrinsic value of the materials in which he usually exercised his talents offered to tasteless cupidity; and which often no doubt led to the destruction of fine specimens of art for the sake of the gold or silver in which they were worked.

The life of Benvenuto Cellini, written by himself, is, in its class, one of the most curious and interesting biographies extant. It not only contains very full information respecting the life and professional pursuits of an extraordinary individual, and describes all ranks of persons with whom he was connected during a long and busy career, but furnishes a lively and no doubt tolerably accurate picture of the state of society during the greater part of the sixteenth century. Cellini's vanity and self-satisfaction, displayed throughout the work, are excessive and highly ludicrous; and, candid or reckless, he does not disguise the excesses into which an ardent temperament and ungoverned passions too frequently urged him. To the dishonour of those who held the reins of government, and especially in the States of the Church, his narrative shows how easily crime was overlooked when the delinquent had talents (either useful or agreeable to his judges) to plead in his behalf, or courtly interest to protect him from the just consequences of a disregard of the laws.

The best edition of Cellini's life is entitled '*Vita di Benvenuto Cellini da lui medesimo scritta, &c. &c. da Gio. P. Carpani*,' whose notes are valuable, 2 vols. 8vo. 1812. There is a translation into English by W. Roscoe. Cellini also wrote a treatise on various branches of his art.

CELLULACEA. [CEPHALOPODA.]

CELLULAR TISSUE, one of the primary substances of the animal organization, the simplest form of membrane, that which is conceived to constitute the original structure from which all the others are produced. It is more extensively diffused than any other animal substance, and may be considered as forming the basis of the animal body. When in thin slices, cellular membrane appears as a semi-transparent or colourless substance; when examined in thicker masses it is of a whitish or greyish colour. It consists of minute threads, which cross each other in every possible direction, leaving spaces between them, and thus forming a mesh or net work, not unlike the spider's web. The inter-spaces between the threads are not, properly speaking, cells, for there are no such distinct partitions as the ter-

mines its name, results from the intersection of its component threads or fibres in every possible direction. These inter-spaces during life and in the state of health are filled with a thin exhalation of an aqueous nature, a vapour rather than a fluid, rendering and keeping the tissue moist. This vapour consists of the thinner part of the blood, which is poured into the interstitial spaces by a process of secretion. When occupying these spaces it makes no long abode within them, but is speedily removed by the process of absorption. In health these two operations exactly balance each other, so that there is no accumulation of the aqueous fluid, but merely enough is effused to keep the tissue always in a state of suppleness. The cellular thread or fibre is capable of great extension and is highly elastic; and some of the most important purposes which it serves in the economy depend upon its property of elasticity.

When examined by the microscope, the component threads of the cellular tissue appear, according to some observers, to consist of minute particles of a globular figure; according to others, the fibres, which are very distinct, are not composed of globules, although globular bodies are seen at irregular distances, either singly or clustered together; but such globules never present a linear arrangement. The threads consist, it is conceived, of conglutinated and condensed albumen. When arranged in the form of membrane so as to constitute cellular tissue, these threads are everywhere penetrated by arteries, veins, absorbents, and nerves, endowing the tissue with properties truly vital. These vital properties are certainly possessed in a less degree by cellular tissue than by any other organized substance; yet, as has been already stated, it is the seat of at least two vital properties, secretion and absorption. However, the most manifest and perhaps the most important purposes which this tissue serves in the economy, depend upon its physical properties of cohesion, flexibility, extensibility, and elasticity.

It is proved by minute and accurate dissection, that cellular tissue is continued uninterruptedly all over the body, and hence that it constitutes the common bond of union between the different regions into which the body is divided, and the several organs contained in them. At the same time it enters very largely into the composition of all the organic solids, many of which are entirely composed of this substance variously modified and arranged.

In this manner the cellular membrane of the body consists of two portions, one of which fills up the interstices which are left between the various organs, and thus unites them with each other; and the other portion closely surrounds the organs, penetrates into their interior, and contributes largely to their formation. The first, called the common or external cellular tissue, has the general extent and figure of the body, constituting the mould of its individual parts; the second, termed the special or internal cellular tissue, envelops the individual organs and enters as a constituent element into their structure. The quantity of the first is by no means the same in all the parts of the body. Considerable masses of it are accumulated wherever there is extensive motion, as in the fore part of the neck, at the flexures of the joints, in the palm of the hand, before the ankle, and in the sole of the foot. Still larger masses of it are collected in the great cavities and surround the viscera, as the liver, the pancreas, the kidneys, &c. Its density is widely different in different situations; in the palm of the hand and the sole of the foot it is firmer and closer in its texture than around the liver or the kidney; and in some places its density is so great that it constitutes a peculiar structure termed fascia; as under the skin of the abdomen, in the perineum, at the side of the neck, and around the forearm and the thigh. It becomes finer as it divides and subdivides, in order to include the more delicate organs. Thus the sheath which forms to envelope the muscular fasciculus is of a coarser texture than that which it affords to the muscular fibre, and the covering which it gives to the trunk of the nerve of the extremities is firmer and denser than that which it spreads around the soft and delicate nerve of sense. (Grainger and Craigie's *Elements of General Anatomy*, and Southwood Smith's *Philosophy of Health*.)

CELLULAR TISSUE is that kind of elementary organic matter in plants which answers to the flesh in animals. It forms the parenchymatous and pulpy parts, and all those which are allied to them. It may be said to constitute the basis of vegetation, never being absent from any plants, often, as in mosses, forming their entire substance, and always being that among which the woody and vascular tissues

penetrate. The pith, the soft parts of the bark, the green web that lies between the veins of the leaves, the flesh of fruit, &c. &c., consist of cellular tissue. When examined with a microscope, it is found to consist of little vesicles of semitransparent matter, adhering with considerable tenacity, and varying in figure from that of a spheroid to a rhomboidal dodecahedron, and thence to prismatical and other forms. It is probable that all the other kinds of tissue are developments or modifications of this; for in most seeds it is the only kind which exists in the embryo, and yet immediately after germination commences, both woody tubes and spiral vessels make their appearance. We must, therefore, conclude either that those organs are modifications of cellular tissue or that they are spontaneously generated. For a full account of the varieties and uses of this kind of tissue, see Lindley's *Introduction to Botany*, second edition.

CELO'SIA, a genus of amarantaceous plants, comprehending the flowers which gardeners call cockscomb; account of the crested flattened appearance of their inflorescence. The calyx consists of five narrow sharp-pointed sepals, surrounded by some bracts of the same shape and colour as themselves. The stamens are five, and united into a plaited cup. The capsule is membranous, one-celled, opens by a transverse fissure, and contains two or three seeds. The leaves are always alternate. Only two species are cultivated, namely *C. cristata* and *C. coccinea*.

C. cristata, the common cockscomb, is said to be a native of the East Indies, but it is more probable that it came originally from either Japan or China, for it is only seen in gardens in the East Indies. It varies in regard both to stature and colour, some of the sorts being as much as two feet high, while others do not exceed six inches; in colour it is seen with deep blood-red, purple, and yellowish-white combs; the latter, however, is seldom cultivated now.

C. coccinea is by no means so striking a plant as the last in appearance, for it forms little or no crest; but it bears its flowers in panicked spikes. It also is said to be a native of the East Indies, and varies with purple and silvery or yellow flowers.

Nothing can be more easy of cultivation than these flowers; and they are capable of being brought to an extraordinary size by good management. Mr. Knight, the President of the Horticultural Society, gives the following account of the method he pursued to procure a specimen of *C. cristata* of the extraordinary size of eighteen inches in width, seven inches in height, and of the most intense colour. 'In cultivating these plants, I have treated them precisely as I do my pine-apple plants, having in some respects a similar object in view; for in both a single fruit-stalk of great strength is requisite, the protrusion of which should be retarded as long as possible consistently with the rapid growth of the plant. The compost I employed was the most nutritive and stimulating that I could apply, consisting of one part of unfermented horse dung, fresh from the stable and without litter, one part of burnt turf, one part of decayed leaves, and two parts of green turf, the latter being in lumps of about an inch in diameter, to keep the mass so hollow that the water might have free liberty to escape, and the air to enter. Manure was also given in a liquid state by steeping pigeon dung in the water, which was given very freely. The plants were put, whilst very small, into pots of four inches in diameter, and three inches deep; as soon as their roots had reached the sides of the pots, and before they had become in any degree matted, they were transplanted into pots of a foot in diameter, and about nine inches deep. Particular attention was paid to the state of the roots, for I have reason to think that the compression of them in the pot has, under all circumstances, a tendency to accelerate the flowering of plants. Under this mode of treatment the plants became large and strong before they showed a disposition to blossom, they usually divide into many branches (as the pine-apple plant also do), which will greatly injure them, if due attention be not paid to remove the side branches when very young. My plants were at all times so placed that their leaves reached within a few inches of the glass, and they were subjected to the same heat (from 70° to 100°) during the summer as my pine-apple plants.'

CELSIUS, ANDREW, born 1701, at Upsal, 744. He must not be confounded with his father (or grandfather) **Celsius**, 1670-1756, a theologian, or with his grandfather **Magnus Nicholas Celsius**, 1621-1679, a mathematician and botanist. Andrew Celsius joined Maupertuis and his asso-

ciates in the measurement of the Lapland degree, and afterwards built an observatory at Upsal. He was the first who employed the centigrade thermometer. He wrote various works, of which it will be worth while to note, 1. his astronomical and meteorological observations in the Upsal Acta Literaria; 2. his collection of the aurora boreales observed at his time in Sweden, under the title 'CCCXVI Observationes de Lumine Boreali, Nuremberg, 1733.'

CELSUS, AURELIUS * CORNELIUS, appears to have lived in the Augustan age, but this point is by no means settled; and, as Le Clerc observes, some suppose him to have lived under Tiberius, Caligula, Nero, or even Trajan. Yet there is strong evidence in favour of our supposition. Columella, who wrote under Claudius, speaks of 'Julius Atticus et Cornelius Celsus, celeberrimi ætatis nostræ auctores.' (*De Re Rusticâ*, lib. iii. cap. 17.) And in another place he says, 'Nostrorum temporum Cornelius Celsus totum corpus disciplinæ quinquæ libris complexus est.' (*Ibid.*, lib. i. cap. 1.) Again Celsus, in his preface, after mentioning Asclepiades, says, 'Ex ejus successoribus Themison nuper ipse quoque quædam in senectute deflexit.' Now we know that Asclepiades was a contemporary of Cicero; and Pliny tells us (xxix. 1), that Themison was a disciple of Asclepiades. We may therefore not unreasonably conclude with Dr. Milligan, that Celsus was a contemporary of Horace and Ovid. This probability is strengthened by his style, which resembles that of the best writers of the Augustan age.

Nor has the profession of Celsus been thought to be perfectly ascertained; for it has been conjectured that he was not a practical physician, but an amateur, who wrote upon physic as forming a part of philosophy. The observations of Celsus, however, on the most practical points, exhibit such familiarity with the subject, that it is impossible to suppose they could have proceeded from any but an actual physician; and there are several passages in his works which hardly be supposed to refer to any thing but his practice. Thus after mentioning the method adopted by Heracleides of Tarentum in cases of adhesion of the eyelid to the eyeball, he remarks, that he did not recollect to have seen it successful in a single instance (lib. vii. 7).

Celsus wrote treatises on agriculture, rhetoric, and military affairs, as well as on medicine; but all have been lost except the treatise 'De Medicinâ,' and some fragments of his work on rhetoric, published by Sextus Popma. The work on medicine consists of eight books; the first gives a brief account of the history of medicine, and of the regimen to be observed by persons of various constitutions; the second, of prognosis and diet; the third, of the treatment of general diseases by diet; the fourth, of the treatment of partial diseases; the fifth, of medicines and diseases to be treated by them; the sixth, of the treatment of local diseases by medicine; the seventh, of surgical operations; the eighth, of the bones, with their diseases, fractures, and dislocations. Hippocrates and Asclepiades are the chief authors whom Celsus follows. He copies the former when he treats of prognosis and of various surgical operations, where he translates, word for word, a great number of passages; owing to which circumstance he has been called the Latin Hippocrates. But in other points he rather preferred Asclepiades; whence he has been classed by some in the sect of methodists. But not to mention the perfect impartiality with which he speaks of the three principal sects existing in his time, namely, the empirics, dogmatics, and methodists (lib. i., Pref.), his practice shows that he was not a blind adherent of any party. Celsus merited the praise of an eclectic physician, and followed the sect to which he seems to incline, only so far as they followed nature. In opposition to Hippocrates, but in conformity with Asclepiades, Celsus rejects the doctrine of critical days*, which he supposes to be an offshoot of the Pythagorean numbers. Nor did he copy Hippocrates in the great question of bleeding, which he used far more frequently. 'It is not new,' says Celsus, 'to take blood from a vein; but to do so in almost every disease is new. So it is an old practice to bleed young persons, and women who are not pregnant; but it is only of late that boys and old men, and pregnant women, have been bled; as the ancients

* His first name is uncertain: Aldus makes it 'Aulus.'

† Critical days are those which produce a crisis, or opportunity of the termination of an acute disease. The critical days were supposed to be the third, the fifth, the seventh, the ninth, the eleventh, the thirteenth, and the twenty-first; of these the seventh, the fourteenth, and the twenty-first, were the most important.

now that the earliest and latest periods of life this remedy, and were persuaded that a pregnant woman thus treated must miscarry. But experience has shown, that no one of these rules was without an exception, and that other points were more deserving of attention, in order to regulate the treatment. For the important point is not whether the patient is pregnant, or what his age, but what is his strength. Thus if a young, weakly, or a woman who is not pregnant is not strong, venesection is injurious; for it will destroy any remains of strength. But a vigorous boy, a robust old man, or a strong pregnant woman, may be bled with safety. Yet an unskilful physician may be very much deceived in these points, because these stages of life are commonly deficient in vigour, and a pregnant woman requires strength after the termination of the medical treatment to maintain not only herself but her offspring. (*De Med.* lib. ii., 10.)

Celsus bled in fever when the symptoms were violent, the skin red, and the veins full; in pleurisy; in peripneumony if the patient was strong, but if not, dry cupping was to be employed; in paralysis; in convulsions; in dyspnoea, when it threatened suffocation; in apoplexy; in cases of unbecoming in internal contusions; in spitting or vomiting of blood; and in all acute diseases, when he thought that the patient had too much blood. He also bled in cachexia. These instances show that he bled more frequently than Asclepiades, but not more frequently than modern practitioners, excepting indeed in the article of cachexia. Celsus used cupping glasses, both with and without scarification; but it is remarkable that he does not speak of leeches, though they were used by Themison.

As Celsus differed from Hippocrates on the subject of bleeding, so he did likewise on that of purging. After remarking that the antients purged and administered clysters in almost every disease, he says that aperients injure the stomach, and that the patient is weakened if the bowels are too much moved, either by medicine or clysters; and he recommends the practitioner to abstain from their use in fever.

The first four books also direct the method of employing gestation, friction, baths, fomentations, and the sudorific treatment. As to diet, patients are to abstain from eating and drinking at the beginning of their maladies, but they must afterwards take food in moderate quantities.

Among the numerous remedies contained in the fifth and sixth books, but few are to be taken internally; by far the greater number are unguents, plasters, cataplasms, &c. Among the exceptions are three antidotes; the first is a compound of opium (*laqueria papaveris*) and aromatics; the second, called ambrosia, and said to have been composed for one of the Ptolemies by Zopyrus, consists of aromatics without opium; the third, again, contains opium, and is the famous Mithridate, by which Mithridates is said to have secured himself against poison. This remedy preserved its reputation for 2000 years, and may be still said to survive in the *confectio opi*.

The seventh and eighth books give a very favourable idea of the progress which surgery had made in the Augustan age. The operation of lithotomy, as described by Celsus, has been much praised and very extensively adopted. Mr. Samuel Cooper observes that it was longer practised than all the other methods, 'having been continued to the commencement of the sixteenth century; and it was performed at Bordeaux, Paris, and other places in France, on patients of all ages by Raoux, even so late as 150 years ago. Frère Jacques occasionally had recourse to it; and it was successfully executed by Heister (part ii., chap. 140). A modern author recommends it always to be preferred on boys under fourteen.' (Allan, p. 12.) (*Surgical Dict.* art. 'Lithotomy'.)

Among the most remarkable points in this division of his work we may mention the account of cataract, and the operation with the needle for its cure (lib. vii., 7); the two-fold treatment of goitre by caustic, and extirpation (vii., 13); tapping in dropsy (vii., 15); the restoration of the prepuce in the circumcised (vii., 25); the employment of the catheter (vii., 26); manual delivery in cases where the child is dead (vii., 29); and the treatment of fractures and dislocations in the last book. Nor will the account given by Celsus of the structure of the human body fail to surprise those who have been told that the antients were ignorant of anatomy.

A edition of Celsus is that of Nicolaus Florent, 1478; the editions are those of Krause, Leipzig, 1772; of Vallart, Lutet., 1772; the 8vo. edition

at Leyden in 1746; and the one edited by Dr. Milligan, second edit., Edin., 1831. Celsus has been translated into several modern languages. There is a translation into English, with notes, critical and explanatory, by Dr. Boerhaave, London, 1756, 8vo.

Histoire de la Médecine par Le Clerc; *Disertation de Celsi vita*, prefixed to Dr. Milligan's edition.

CELSUS. [ORIGENES.]

CELÆ, the name of an antient race, which, according to the oldest historical records, occupied a great part of central and western Europe. The Celæ appear to have been divided into two great families, the Gauls (Galli, in Greek Κελται and Γαλάται), who occupied the country of that name from the remotest epoch on tradition, and who in their own language called themselves Celæ; and the Cymri, who are by some considered to be the same as the Cimærians (Κιμῆριοι), who appear to have migrated westwards later period from the countries bordering on the sea of E., and, advancing along the Danube, to have spread themselves across Germany to the Ocean. The latest inquiries into the Celtic language show a clear affinity between it and the languages called Indo-Germanic by modern philologists. The earlier Greek writers had very confused notions about the Celæ. Herodotus (iv. 49) places Celæ at the sources of the Danube, and in the remotest west of Europe, beyond the Cynetes (an unknown people); but he does not mention them in his enumeration of the various nations who furnished the Carthaginians with mercenaries for their Sicilian wars. In the first Punic war we find Gaulish troops in the Carthaginian service. Other Greek writers confound the Celæ with the Scythians, others with the Germans or Teutones (Fabri *Thesaurus*, art. *Galli et Galatæ*, and references there). The messengers who carried to Athens the news of the burning of Rome by the Gauls (B.C. 382, according to Niebuhr), said that it had been effected by a great host of Hyperboreans, who had come over the icy mountains from the unknown regions of the north. (Plutarch's *Camilus*.) But long before this the Celæ of Gaul had crossed the Alps, under Bellovesus, into N. Italy, and had become known to the Romans by the name of Galli, 'Gauls,' which seems to have been an aboriginal name of the oldest tribe of the Celæ settled in W. Europe. Livy and other antient historians fix the immigration of Bellovesus in the reign of Tarquinus the elder; but Niebuhr is inclined to place it at a much later date. It is evident however that there were several immigrations of the Gauls into N. Italy, and at different times. The Galli, who occupied the plain N. of the Po, drove away the Etruscans, but they never conquered either the Veneti, who were settled E. of the Athesis (Adige), or the Ligurians, who occupied the country S. of the Po to the Mediterranean and the river Macra. The various Gaulish tribes that immigrated into Italy are believed to have belonged to the Ædii, Lingones, Ambarri, and Carnutes, who have left traces of their residence in N. Italy. The Insubres are said by some to have been a division of the Ædii. (Bossi, *Storia d'Italia*, vol. ii. ch. 9.) The Cenomani seem to have belonged to a later immigration; they occupied the country of the Orobii, the previous inhabitants of the hilly region about Como and Bergamo. Cato (*De Origin.*) says that the Orobii were not Gauls. The Boii were likewise a later immigration of Gauls, who crossed the Po and occupied the country S. of that river. [Boii.] Lastly, the Senones spread S.E. of the Boii, along the Adriatic coast, as far as Picenum. The Gauls never made a permanent settlement in Italy south of the Apennines.

Contemporary with the first recorded immigration under Bellovesus, another host of Gauls, under Segovesus, crossed the Rhine, and, advancing as far as the Hercynian forest, settled along the Danube, and in the country now called Bohemia, from which they were afterwards driven by the Marcomanni and other Teutonic or German tribes. Some of them penetrated into Illyricum, and settled among the Illyrians. The Scordisci, south of the Danube, appear to have been a tribe of Gauls. In very remote times the Celæ of Gaul crossed the Pyrenees and conquered part of Spain, where their descendants, mixed with the aboriginal Iberians, formed the nation known to the Carthaginians and the Romans by the name of Celtiberi. Some colonies of Celæ penetrated to the W. extremity of Spain, and we find them mentioned in the antient geographers under the name of Celtici, both on the banks of the Anas (Gadiana) and on those of the Minus (Minho) in N. Lusitania.

The Gauls likewise are said to have crossed the sea into Britain, which they occupied. [BRITANNIA.] But while the Gauls were thus spreading their colonies to the E., the W., and S., they were themselves pressed upon from the N. by the Cymri or Cimmerians, who appear to have been a branch originally of the same stock as the Gauls, and who had occupied W. Germany. The Belgæ are believed by some to have been a mixed race of Cimmerians and Germans. Appian (*De Reb. Gall.*) says, that the Nervii, one of the chief Belgian tribes, were descendants of Cimbrians and Teutones. The epoch of the great Cimmerian immigration is unknown, and there is much confusion in the ancient historical records between the movements of the Cimmerians and those of the original Gauls. We know that the Belgæ occupied the N. part of Gaul and the S. part of Britain, and drove the Gauls farther inland. It appears also that tribes of Cymri occupied the N. W. coast of Gaul, for the Veneti of lower Brittany were called Cymri or Cimbrians, as distinct from Celtic Gauls around them. Diodorus (v. 32) says, that Belgæ was the old name of the Cymri, and he quotes Posidonius, who calls them Galatæ or Cimbrians, while he calls the Gauls by the name of Celts. Ammianus Marcellinus (xv. 9) records as a tradition of the Druids that a portion of the Celts came into Gaul from beyond the Rhine, and passed afterwards into S. Britain, from whence they drove the original Gauls farther inland. The distinction between Gauls and Cymri has been perpetuated, at least in name, down to our days, in the Gaels of Scotland and the Welsh, the language of the latter being called Cymri, as well as that of the Armoricans, or inhabitants of Brittany, while that of the Gaels of Scotland is called the Gaelic. The Cimbri of Marius appear to have been a tribe of Cymri who had settled in N. Germany, or, according to some ancient writers, among the Scythians, and from them came the Celto-Scythians, who joined the Cimbri in their westward irruption. (Plutarch, *Marius*.) There is sufficient similarity between the manners and institutions of Gauls and Belgians to make them appear cognate races: both had a powerful Druidical hierarchy; both were divided into optimates, or freemen, and the common people, who appear to have been little better than serfs; both were hasty, violent, and impatient (Niebuhr, *History of Rome*, vol. ii., where he treats of the Gauls and their immigrations); both appear to have been distinct from the Teutonic or German race, as well as from the Iberian and Ligurian.

About 280 B.C. a vast multitude of Celts or Gauls invaded Macedonia and Greece. According to Justin they started from Pannonia, where their ancestors had settled long before. It is probable that they were joined by other tribes, either of Celtic Gaul, or of Cymri, coming from W. Germany, or of both. Justin mentions among them the Teutosages, from the neighbourhood of Tolosa, but his account is very confused and contradictory. (Compare b. xxiv. 8, with b. xvii. 3.) The invaders were divided into two great bodies: one under a chief, whom Justin calls Belgus, and Pausanias Bolgos, invaded Macedonia, spreading terror and desolation everywhere before them. Ptolemaeus Ceraunus, king or usurper of Macedonia, having attempted to oppose them, was defeated and killed. They made an immense booty, plundered the temples without scruple, and then retraced their course homewards. The other host of Gauls, under Brennus, entered Macedonia the following year, 279 B.C., and defeated Sosthenes, who, after the death of Ceraunus, had assumed the government of that country. Brennus then advanced through Thessalia, and southwards as far as Delphi, with the intention of plundering that rich sanctuary. The Gauls were however put to flight, partly by the resistance of the people of Delphi, and partly, it is said, by an earthquake, which took place during the attack, and which was followed by a fearful storm. These phenomena were attributed to the wrath of the offended God. The attack on Delphi appears to have taken place in 278 B.C. (Clinton, *Fest. Hellenici*). Brennus, through mortification, killed himself. The Gauls lost vast numbers in the repulse, and still more in their retreat northwards, being harassed by the hostile populations. Another incursion of Macedonia was made soon after by another host of Gauls who had not been in the expedition, but had waited on the frontiers. (Justin, lxxi. 1.) After defeating the Getæ and Triballi, they were met by Antigonus Gonatas, and totally routed. The remnants of these expeditions withdrew into Thrace, where parties of Gauls had been in the habit of making incursions, to the

great annoyance of the Byzantines. [BYZANTIUM.] Being however invited by Nicomedes I., king of Bithynia, who was then at war with his brother Zibobtes [BITHYNIA], and being provided by the same with boats, they crossed over into Asia, and effectually supported his claims to the throne.

They then settled in the interior of Asia Minor to the west of Bithynia, and occupied a great tract of country, or from them was called Galatia and Gallogrecia. It was bounded N. by Paphlagonia, W. by Phrygia and Bithynia, E. by Cappadocia, and S. by Phrygia and Pontus.

Frequent incursions into the neighbouring country were checked by Antiochus I., who defeated them, and was in consequence called Soter or Saviour. Three principal tribes of Gauls are mentioned as having settled in the country: the Teutosages, whose principal town was Ancreya; the Tolistobogi, who lived near the sources of the Sangarius, and whose principal town was Pessinus, famous for its temple of Cybele; and the Trocmi, who lived more to the E. near the banks of the Halys. (Loake's *Asia Minor*.) The Galatæ are frequently mentioned in subsequent history as mercenaries in the armies of the kings of Bithynia and of Pontus, and also in those of the later kings of Macedonia and of Syria. They seem to have had their own kings or chiefs, some of whom are mentioned in history; among others, one Cavarus, who acted as mediator between Prusias I. king of Bithynia, and Attalus king of Pergamum. Sestini has given an account of several medals of Cavarus and other kings of the Gallogreci. During the war of the Romans against Antiochus III., the Consul C. Manlius invaded Gallogrecia 189 B.C., for which he obtained the honour of a triumph 186 B.C. (Livy, 38 and 39.) Mithridates the Great, in his wars against Rome, occupied Galatia, and we find the Galatians forming an essential part of his troops. One of their chiefs, however, Deiotarus by name, forsook the part of Mithridates in favour of Rome, in consequence of which he was acknowledged as king by the Roman Senate. It was for the son of this Deiotarus, called also Deiotarus II., that Cicero pleaded.

After this Galatia became a province of the Roman empire. Several names of places in Galatia attested the relationship of the new settlers to their western brethren, such as Ecobriga, Tolistochora, &c.

The power of the Gauls in Europe was evidently on the decline long before Cæsar's conquest of their country. They were pressed on one side by the Belgæ and the Germans, and on the other by the Iberians, who had settled in Aquitania. The Gauls of Italy had been all subjugated by Rome. The Romans had also occupied the Province of Narbo, which originally belonged to the Celtic Gauls. For the names and localities of Celtic Gaul in Cæsar's time, see CÆSAR; and for those of the Celts of Britain, see BRITANNIA.

The distinguishing features, both physical and moral, of the Celtic race, whether Gauls or Cymri, are described by most ancient writers, especially Cæsar, Livy, Diodorus, Appian and Justin; but their accounts are not free from contradictions. They were men of large size, of fair complexion, reddish hair, and fierce aspect. They could bear cold and rain, but not heat or thirst. They were vain and boastful, clamorous and impatient of control, and quarrelsome among themselves. Their first onset was formidable, but if once repulsed they easily gave way and dispersed. Their swords were long and unwieldy; those of the Celtic Gauls appear to have been of copper, but they bent after the first blow, which gave a great advantage to the Romans over them. The Gauls fought generally naked down to the loins. Their shields were large and oblong; but they appear to have been slight and ill contrived for protection. Livy (xx. 46) well describes the contrast between the appearance of the Gauls in Hannibal's army and that of the Spanish mercenaries. Their government was aristocratic; the optimates or nobles formed the senate or supreme council: the common people seem to have had no political rights, and to have been in a state of depression. We find that one more powerful tribe, such as the Bituriges and Ædui, exercised, at least for a time, a sort of political supremacy over the neighbouring tribes. Their kings or chiefs appear to have been elective, and to have held their office only for a year or two, unless re-elected. The Druids formed a powerful hierarchy; they were interpreters of the law, and judges in civil and criminal matters. The Druids seem to have been an hereditary or though not exclusive, being recruited from the young men of noble families who resorted to their schools. (Cæsar, *De Bello Gall.* vi. 13) gives a good

attentions of the Gauls in his time, which he contrasts with those of the Germans. He says that Druidism was supposed to have come from Britain into Gaul. The religion of the Celts was originally a sort of theism; they had no idols or images, against which they showed a particular aversion in their invasions of other countries; they worshipped the Supreme Being in sacred groves. The oak and the mistletoe were sacred. They afterwards adopted some of the gods of the Germans and other nations. They had also bards who were not only poets but soothsayers, and their songs were transmitted by tradition. The Druids offered human sacrifices, and they drew omens from certain appearances in the limbs and blood of the victims, and also from the flight of birds. The latter was resorted to in case of emigration to direct their course. Diodorus (v.) says that the Druids had instruments by which they could bring distant objects either on the earth or in the heavens nearer to them. He tells some wonderful stories of the Celts or Gauls, which show how little that people were known at Rome even in his time. He says that 'those who inhabit farthest north towards Scythia are the most ferocious, and they are said to devour human flesh, like the Britanni who inhabit Iria (Ireland).' The Celts of Gaul had attained a considerable degree of civilization and luxury when Cæsar entered their country. They seem to have been acquainted with the Greek language by means of the colony of Massilia (Marseilles), and the Greek alphabet was in use among them. We do not know of any original Celtic alphabet, nor of any works in their language. Indeed we have no knowledge left of the language of Celtic Gaul, unless we suppose it to have been similar to the Gaelic of Scotland. The Breton language, like the Welsh, is a dialect of the Cymri language belonging to that great division of the Celts. It has been long disputed whether the Basque language is a dialect of the old Celtic. W. von Humboldt (*Prüfung der Untersuchungen über die Urbevölkerung Hispaniens vermittelst der keltischen Sprache*, Berlin, 1821) seems to be of opinion that the Basque language is of Iberian and not Celtic origin. The remains of the old Celtic language must therefore be sought in the Gaelic, and in the Erse or Irish, which is said to resemble the Gaelic; and in the Welsh and its cognate dialect, the Breton. These seem to be the only probable off-spring of the Celtic Gauls and the Cymri, Cimmerian, or Cimbric. For further information concerning these two great families, we must refer our readers, besides the ancient writers mentioned in this article, to the numerous modern works written professedly on the subject, among others to P. Bæmus, *De Moribus Veterum Gallorum*; Jos. J. Pontanus, *Glossarium Præcæ-Gallicum*; Risco, *España Sagrada*; Münnert, *Geographie der Griechen und Römer*; Davios's *Celtic Researches on the Origin, Tradition, and Language of the Antient Britons*; *Mémoires de l'Académie Celtique*; Amédée Thierry, *Histoire des Gaulois depuis les Temps les plus reculés*, Paris, 1828; besides the numerous English works on the Gaelic and Welsh languages and antiquities.*

CELTIBERI, a people of ancient Spain, supposed to have been descended from Celts who in remote times immigrated from Gaul, and afterwards became mixed with the native Iberians, so as to resemble in their habits more the latter than the former people. The Celtiberi extended from the right or S.W. bank of the Iberus (Ebro) towards the interior of Spain. They occupied the highlands about the sources of the Duero and the Tagus, and both sides of the great central ridge which divides the waters which flow E. towards the Mediterranean from those which flow W. into the Duero and the Tagus. [CASTRILLA.] The Celtiberi are spoken of by the Greek and Roman writers sometimes as a single people, sometimes as a confederation of various nations. In latter sense they extended over a great part of central Spain, including the Arevaci, Pelagones, Lusones, Belli, Tithi. Appian places even the Vaccei among the Celtiberi. Numantia, in the country of the Arevaci, is said by Florus to have been defended by 4000 Celtiberi. The principal towns of the Celtiberi were Segobriga, not far from Numantia, and different from the Segobriga, now Segorbe, near Valencia; Turiaso, now Tarazona; Bilbilis, the place of Martial, now Calatayud; Argobriga, &c. The Celtiberi were a brave and superior to the Lusitani in firmness, and they proved formidable both to the Carthaginians and the Romans. After having submitted to Rome in the second Punic war, they repeatedly engaged in contest, fought against Fulvius Placcus, were subju-

gated by Titus Sempronius Gracchus 179 B.C., revolted a few years after again under the prætorship of Appius Claudius, and were again defeated. They fought afterwards against C. Marcellus and Licinius Lucullus. After the destruction of Numantia by Scipio Æmilianus they were subdued. Their country became part of the Roman Provincia Tarraconensis. (Appian, *Rebus Hispaniæ*; Livy, &c.)

CELTIC ARCHITECTURE. Under this term, we class the structures or buildings which are usually considered to be Druidical; such as the works of the natives of our island anterior to the arrival of the Romans. The beginnings of architecture are undoubtedly perceptible in the sets or compages of stones (each consisting of two uprights and an impost), which form so striking a feature in the circles of Stonehenge. The upright pillars have evidently undergone shaping; and the mode in which the imposts were secured by mortises and tenons shows a regular principle of construction beyond that of the mere rude masses which mark the Druidical remains of other countries. Cells of the Druidical age are also still to be found of a uniform character; such as in the monument called Ty Itud, or St. Itud's hermitage, in Man Hamnwich parish in Brecknockshire (see Gough's edit. of *Cand. Brit.*, fol., 1789, vol. ii., p. 476), composed of four large flatish rude stones, three of them pitched in the ground, and the fourth laid on them as a cover, forming a cell or hut open in front, about eight feet long, and four wide and high. It corresponds with Kit's Coty House in Kent, and with similar cells in other parts. These latter structures are usually known by the name of Kistvaens, and are by some supposed to have been tombs: they appear at all events to have formed a superior class of buildings; for, according to Diodorus Siculus, the ordinary dwellings of the Britons in summer were for the most part meanly built of reeds or wood. Caverns seem to have been their usual places of dwelling in the severer seasons. A Kistvaen, formerly existing at Rollwright in Oxfordshire, was formed of six stones. (Gough's edit. of *Cand.*, vol. ii., p. 382.) King, in his *Munimenta Antiqua*, vol. iii., p. 31, gives an account and representation of the tower of Brunless or Brwulys in Brecknockshire, which he considers an instance of Syrian architecture as used among the Cornish Britons. It is a keep or tower of singular construction, unlike anything Roman or Norman.

CELYPHUS, a genus of Dipterous insects of the family *Lauraniæ* (Macquart). Characters: antennæ wide apart, as long as the head, stylet rather thick and covered with fine hairs; scutellum convex, and covering the abdomen.

This genus is one of the most extraordinary among Dipterous insects, the species having more the appearance of little beetles than two-winged flies; the peculiarity is caused by the immense size of the scutellum, which covers the whole abdomen and encloses the wings when at rest*.

Celyphus oblectus is about one-sixth of an inch in length; the head is yellow; the last joint of the antennæ is black; the thorax and scutellum are of a bluish black colour with violet reflexions; the former is broader than long; the abdomen is fawn-colour, the legs and wings are yellowish, the latter with the base brown. It inhabits Java.

C. scutellus, the only other species known, very much resembles the one just described, but is of a greenish copper colour above and beneath: it is found in the East Indies.

CEMENT, a substance used for causing the adhesion of surfaces, or for covering and protecting them. Cements are of various kinds, comprehending GLUE, LUTES, MASTIC, MORTAR, and SOLDER: their action is purely mechanical, though in some cases, especially in mortar, it is to a certain extent dependent upon chemical changes occurring in the nature of the cement.

On the present occasion our remarks will be almost exclusively confined to those cements which are not comprehended under any of the heads above named; such, for example, as are intended for temporary use, for mending articles which have been broken, or for replacing damaged parts.

Temporary cements are such as are used for holding articles firmly during the operations of the workmen, and which are easily removed when there is no further occasion for them; thus, in fixing glass plates to blocks to be ground for optical purposes, the following is recommended as a useful cement: melt together four ounces of resin, a quarter of an ounce of bees-wax, and add four ounces whitening, previously made red hot, while yet warm.

* If the large size of the scutellum and its covering the wings when at rest, this genus bears a resemblance to the genus *Scutellum* among the Hemiptera.

cement will also answer the purpose of joining metal plates to be turned in a lathe.

Chasers of gold and silver articles support and hold their work by a cement formed of pitch, resin, and a very small quantity of tallow melted together, and thickened by stirring in brick-dust; this cement may also be used for fixing small steel articles on the blocks intended to hold them for polishing. In winter more tallow is necessary than in summer. Shell-lac is also usefully employed for holding metals, glass, or precious stones, while cutting, turning, or grinding them; the metal or other substance should be warmed to melt the cement.

Permanent cements are prepared with various ingredients. Thus, supposing ornaments of Derbyshire spar or other similar substances to be injured by being chipped or broken, the parts may be restored by using a mixture of seven or eight parts of resin and one of bees-wax, with a little plaster of Paris, melted together. The pieces of spar must be heated until they are hot enough to melt the cement, and this being interposed, the parts are to be pressed together; when the cement is used to fill up the place of any small pieces that may have been lost, the quantity of plaster of Paris must be increased. Sulphur also, placed between the heated surfaces of broken stones, makes a good cement; and when little holes are to be filled up, some of the hardened stone should be mixed with the melted sulphur.

Jewellers, in setting precious stones which have been accidentally broken, cement the pieces together by applying mastich between the fragments, which are sufficiently heated to melt this resin; they are then pressed together to force out the excess of mastich. A cement for glass and porcelain is made from a mixture of lime and white of egg; and the same purpose is also answered by dissolving gum arabic in a little water, adding proof spirit and gum ammoniac to it. Another cement for the same use is prepared by mixing three parts of isinglass soaked in warm water for half an hour; pour off the water and add one part of gum ammoniac, previously dissolved in proof spirit of wine; the mixture is to be heated until a drop of the composition becomes instantly stiff by cooling. When used to join broken porcelain or glass, the pieces should be first warmed; the fluid cement should be laid on with a brush, and the pieces pressed together; or, if necessary, tied to prevent their separation.

Japanese cement is said to be prepared by mixing rice-flour intimately with cold water, and then boiling the mixture; it is white, and dries nearly transparent. It is therefore very useful in the manufacture of curious paper articles, which require layers of paper to be cemented together. When made with a smaller quantity of water, models, busts, &c., may be formed of it.

A cement used for steam-engines is prepared as follows: take two ounces of sal ammoniac, one ounce of flowers of sulphur, and sixteen ounces of cast iron filings or borings. Mix them well by rubbing in a mortar, and keep the mixture dry: when it is wanted, take one part of this powder and twenty parts of clean iron borings or filings, and mix them thoroughly by grinding in a mortar; add enough water to give a proper consistence, and apply it to the joints. In this case chemical action goes on, sulphuret of iron being slowly formed, and a great degree of hardness is acquired.

In joining the flanches of iron cylinders, a mixture of litharge, red and white lead, boiled in linseed oil, is made use of. It may be applied spread on flannel, or linen placed between the joints before they are screwed together. The proportions of the ingredients are not important, provided too much oil be not used, so as to make the composition too thin. This cement answers for the joints of stone cisterns intended to hold water.

Coppersmiths lay over the rivets and edges of the sheets of copper in large boilers a mixture of quicklime and ox's blood. It must be applied fresh made, as it soon hardens; this cement is both cheap and effectual. (*Phil. Mag.* vol. xiv.)

According to Mr. Singer, a good cement for electrical apparatus is prepared by melting together about five pounds of resin, one pound of bees-wax, one of red ochre, and about two ounces of plaster of Paris.

CEMENT, PARKER'S. [MORTAR.]

CEMENTATION. [STEEL.]

CEMETERY. [BURIALMENT.]

CENCHRIS, a genus formed by Mr. Gray of the subdivisions of *Boa*. [XIPHOSOMA.]

CENIS MOUNT. [ALPS.]

CENSER, a vessel used for burning and wafting incense: from the French *encenser*, to perfume. It was

called by the Romans

Thymiastrium Sacerdotum, and by the

Hebrews were a sort of chasing-dishes, or burning-pans, with or without handles, which the high-priest placed on the altar of incense, or carried into the sanctuary. St. John in the Revelations (v. 8), speaking of the censers held by the four and twenty elders, calls them dishes, or golden censers, full of incense: such probably as occur upon the reverse of the coins of Simon Maccabeus. Josephus speaks of a very large number of golden censers, made by order for the Temple at Jerusalem. A censer with issuing from it occurs upon some of the Hebrew coins of modern time. Censers are still used in the Roman Catholic worship, and are usually carried by acolytes. (Compare Calmet's *Dict. of the Bible*, 4to., 1797, in voce.)

CENSOR, the name of one of the superior magistrates in ancient Rome. There were two officers of this name, *censures*. They were first created A.U.C. 311, when the consuls were too much occupied with the concerns of war to allow of their making the census themselves. (Liv. iv. 8.) At first they were exclusively of the patrician order: the first plebeian who was elected was C. Marcius Rutilus, A.U.C. 411. (Liv. vii. 22.) In 622 both were plebeians, L. Pompeius and L. Metellus. (Liv. *Epit.* lix.) Originally the censors were chosen by the patrician body, the *curies* (*curiæ*), and their election was confirmed by the centuries: in later times they were chosen by the centuries, and their election was confirmed by the curies; the centuries also passed the law by which the censors formally received their powers: thus the centuries voted twice over. (Niebuhr, vol. ii. p. 394; *of Rome*, by the Society for the Diffusion of Useful

ledge, p. 138.) At first the censorship lasted for five years, but a law was afterwards passed abridging its duration to a year and a half. (Liv. iv. 24.) The office underwent many changes in the time of the emperors. Julius Cæsar acted for several years as *Præfectus Morum*, and subsequently was made censor for life. Augustus performed the functions of the office, but refused the title. Under Tiberius the censorship was abolished (Tacit. *Ann.* ii. 33), and no attempt at its restoration was successful.

When one of the censors died, it was not the custom to choose another in his place: it is true this was once done, but in the same lustre Rome was taken. Superstitious reasons prevented a repetition of the experiment. Accordingly, on the death of one, the remaining colleague resigned, and two fresh censors were chosen. (Liv. v. 31; vi. 27.) Their duties originally were the administration of the public property and revenues, registering the citizens according to their different orders, and keeping the land-tax rolls. In itself the office was insignificant, but in the hands of influential persons it was likely to become powerful. (Liv. iv. 8.) The rank of the citizens and the valuation of taxable property were at the disposal of the censors. The power thus entrusted to them naturally grew with exercise, till in later times it became despotic. No order in the state was exempt from their control. They could exclude a senator from the senate-house, deprive an equestrian of his horse and rank, or remove a plebeian from his tribe. To inspect the manners and guard the morals of the people was a somewhat indefinite commission; and, though parental indulgence and petty family squabbles seem unsuitable subjects for the interference of the state, it is often difficult to determine whether the actions of the censors were in reality over-rigorous, or only conscientiously strict. (Nieb. vol. ii. p. 397.) If a man let his field run wild, the censors considered him unworthy of his order, and forthwith removed him from his tribe. But notwithstanding the immense power which they thus exerted over the rights and privileges of a Roman citizen, no instance is found of their having deprived him of his franchise. When it is said, (Liv. viii. 17) that they added new tribes to the old ones, it is not implied that in these cases they acted on their own independent authority, but only that they, and no other magistrate, proposed to the people the law which effected the addition. (Nieb. vol. ii. p. 399.) They could not, moreover, take the freedom of the city to foreigners, than they could expel from citizens.

They could go no farther than the rank and character of the citizen in their punishments. Whenever they thought a man deserved it, they could brand him with public disgrace—a stigma corresponding to *argua* at Athens. But of this censorian atrophy or ignominy at Rome, there were two kinds. It was inflicted by the censors, sometimes in their own name and authority, and sometimes in the name of a court of law,

only executed. ely censorian
disqualify a man for the functions of a citizen,
sentence to posts of honour: an appeal at
was sometimes actually made from the censor
to the censor himself, even
to punish one another. (Liv. xxix. 37.)
mentions (*Pro Cluentia* 42, 119) an instance of one man
C. Ceta, who had been ejected from the senate by L. Me-
la and L. Domitius, and was afterwards created cer-
sor, who had himself fallen under the cen-
sorship, actually presided over the morals of the
of those very men who had reprehended him.

This was never the case when the censors inflicted the sen-
tence for a judicial court. That sentence, once passed,
they were unable to revoke. (Nieb. vol. ii., p. 397.) The
administration of the public revenues was a part of the
business of the censors, and we find them not only esta-
blishing tolls and excise duties in subject towns, but ac-
tually fixing the price at which salt should be sold in Rome
itself. (Nieb. vol. ii., p. 400.) They let to farm the customs
and the contracts for public works. They superintended the
roads, and took care of the public books and documents.
Cases of marriage and betrothing came under their inspec-
tion. (Varro, *de L. L.* vi. 71, ed. Müller.) Their acts were
registered in public documents; and the purity which was
required in those who filled the office is indicated by the
circumstance, that those documents were preserved in the
temple of the Nymphs. (Cic. *pro Mil.* 27.) The writing was
probably performed by public slaves in the service of the
censors. (Liv. xliii. 16; Nieb. vol. ii., p. 404.)

The censors might be tried when they acted improperly
(Liv. xxiv. 43), and even be led to prison (ix. 34), or thrown
from the Tarpeian rock. (Liv. *Epit.* lix.)

There were also censors in many of the municipia, and
in the provinces. (Cic. in *Verr.* ii. 53.)

In modern times an officer has been appointed in differ-
ent countries under the title of *censor*, whose business has
been to examine all books previous to their publication, and
to see that they contain nothing which the government con-
siders immoral or heretical. In England before the revolu-
tion there was an officer of this kind.

CENSUS, THE, at Rome was a numbering of the
people, and a valuation of their property. It was held in
the Campus Martius. (Liv. iv. 22; Varro *de R.R.* iii. 11.)
Every Roman citizen was obliged, upon oath, to give in a
statement of his own name and age, of the name and age
of his wife, children, slaves, and freedmen, if he had any.
The punishment for a false return was, that the individ-
ual's goods should be confiscated, and he himself scourged
and sold for a slave. Taxation depended on the results
of the census; many kinds of possessions and of actual
property were exempted, while, on the other hand, some sorts
of property were assessed at several times their value.
Constant changes were made by successive censors in the
valuation of taxable property. Cato and Flaccus rated the
taxable value of high-priced slaves at ten times the pur-
chase-money. (Nieb. vol. ii. p. 402.)

According to the valuation of their property at the census,
the citizens were divided into six classes; each class con-
tained a number of centuries or hundreds. That a century
did not always consist of a hundred men is clear, from the
fact that the richest centuries were the most numerous,
and consequently must individually have contained fewer
persons than the centuries of the poor. (*Hist. of Rome*,
by the Society for the Diffusion of Useful Knowledge,
p. 21.) The first class consisted of those whose property
amounted to 100,000 *asses*, about 32½ lbs. of English
money; the second class consisted of persons worth 75,000
asses; the third of the third class amounted to 50,000
asses; that of the fourth to 25,000; that of the fifth to
11,000; and the sixth class included all below the fifth, even
those who had no estate whatever. This was naturally the
fastest of the six, but was accounted only as one century.
Now, as the richer classes contained far more centuries than
the poorer, so much so that the first class contained more
than all the rest together, and as the votes in the *Comitia*
Centuriata were taken within the centuries individually,
and then the vote of the majority of centuries was decisive,
it is obvious that the influence of wealth was greatly pre-
ponderant in this assembly. Cicero (*de Repub.* ii. 22)
assigns this as the object aimed at in the institution. The
real object of the *Comitia Centuriata* was (as Niebuhr sup-
poses) to bind the different orders of the state together in
one consistent and organized body. Every one in the nation

had a vote on national business; and in this assembly was
laid the basis of popular liberty. (See Rev. of Niebuhr, *Edin.*
Rev. CXII. p. 293.) In the *Comitia Centuriata* the people
always appeared under arms, and each class had a particu-
lar kind of armour assigned to it.

The census was held at first by the kings, afterwards by
the consuls; and, from A.U.C. 314, by the censors. After
the census a sacrifice of purification was generally, but not
always (Liv. iii. 22) offered. The victims were a sow, a
sheep, and a bull, which were led thrice round the army,
and then slain: the sacrifice was called *Suovetaurilia*.

It does not appear that the census was held with strict
regularity. It was sometimes altogether omitted. (Liv. iv.
8; Cic. *pro Arch.* 5. 11.) The usual interval was five years;
and in allusion either to the sacrifice of purification, or to
the farmers paying their taxes at this time (Voss, *Etymo-*
log. Ling. Lat. in Aestrum), the interval was commonly
called a lustrum (*lustrum*). It is obvious that the census
must have been of great use in ascertaining the actual
strength and capabilities of the state.

When a person was duly entered on the books of the
censors, this was taken as a proof of his citizenship, even if
he were a slave, provided he had been registered with his
master's consent (Cic. *de Or.* i. 40; Ulp. i. 8); but many
enactments were made to regulate and modify this legal prin-
ciple. As the census was held at Rome, citizens who were in
the provinces, and wished to be registered, were obliged to
repair there on that occasion (Cic. *ad Att.* i. 18, &c.); but this
was sometimes evaded, and was made a matter of complaint
by the censors. The census, accompanied with the ceremony
of the lustrum, seems to have fallen into disuse after the
time of Vespasian; but the numbering of the population,
&c., continued till a late epoch of the empire.

As to the census in the provinces, under the empire, see
Tacitus (*Ann.* i. 31, 33, &c.), and the *Excursus* of Lipsius.
See also Dig. 50, Tit. 15. [DE CENSIBUS.]

The term *census* is also used in Latin authors to signify
the amount of a person's estate, and hence we read of
census equester, the estate of an eque, and *census senatori-*
us, the estate of a senator. (Pitisc. *Lex. Antiq. Rom.*)

CENSUS. The first attempt to ascertain the popula-
tion of England, and to determine its increase or otherwise,
by ascertaining the number of births and burials, was made
in the 18th century. This method could at best afford only
an approximation towards the truth, which can only be sat-
isfactorily ascertained by actual enumeration: while, as re-
gards the important questions of the condition of the people
and their means of subsistence, it is clear that deductions
drawn from registers of births and burials, if even they were
perfectly accurate (and in this country they never yet have
been so), would give no information whatever.

It was provided, among the articles of the Federal Con-
stitution, that a census of the people in the United States
of America should be made 'within three years after the first
meeting of congress, and within every subsequent term of
ten years.' The first census was taken in 1790, and the
fifth, hitherto the latest, in 1830. In the United States,
the object of the census being merely the apportionment of
the number of representatives according to the population of
the several states, the inquiries have not been extended be-
yond obtaining the numbers and ages of the people, distin-
guishing between the sexes, and between free persons and
slaves. No inquiry has been made as to any of those cir-
cumstances which indicate the progress of the people in
wealth and civilization. That this progress has been great
and constant may indeed be fairly inferred from the rate of
increase of the people, which has been great beyond all
means of comparison afforded by the older settled countries
of Europe.

In 1791 a committee of the Constituent Assembly of France
was appointed for the purpose of ascertaining the numbers
of the people in that country. Since that time considerable
care has been taken to keep an accurate record of those
numbers by computations, from year to year, derived from
strictly enforced regulations as to the registration of births
deaths, and by decennial enumeration—the last, and
by the most accurate, which was made in 1831.
of the police, and of the other civil institutions of
France, is favourable for obtaining information upon many
things connected with this subject; and the French
government has availed itself of these means to a consid-
erable extent, for ascertaining the actual condition of the
people.

The first actual enumeration of the people of England

and Scotland was made in 1801, and subsequently in 1831, 1821, and 1831. In Ireland the earliest enumeration was made in 1813, since which time a census has been taken, as in Great Britain, in each of the years 1821 and 1831. It will be sufficient here to explain the heads of inquiry embraced on the last of these occasions, and the method pursued for obtaining information. The actual collection of that information was entrusted, in England, to the overseers of the poor, and in Scotland to the parochial schoolmasters. In Ireland, where there are neither overseers of the poor, nor parochial schoolmasters, the task was entrusted to persons chosen and appointed by the chairman and assistant barristers, the recorders of cities and towns, and the magistrates assembled in sessions for the purpose; one person being so appointed in each parish, with power to call for the assistance of the churchwardens and constables of the parish. The persons thus appointed in the different divisions of the kingdom were respectively required to take an account of the resident population, by proceeding from house to house on the 30th day of May, 1831, and on the days immediately subsequent thereto, if one day was not sufficient; and they were also required to specify in writing the name of the parish or place, and whether it be usually called a parish, township, tithing, quarter, or by what other denomination. Individuals to be numbered only in those parishes, &c., where they severally happen to be at the time of taking the account.

The questions, answers to which were to be thus collected, were sixteen in number, viz.:

1. How many inhabited houses are there in your parish, township, or place, and by how many families are they occupied?
2. How many houses are now building, and therefore not inhabited?
3. How many other houses are uninhabited?
4. What number of families in your parish, township, or place are chiefly employed in and maintain handicraft, and how many in agriculture? or by 1 do, and 2 of the two preceding classes?
5. How many persons (including children of white males found within the limits of your parish, township, or place, actually or in his name) are there actually or in his name of the male sex, or belonging to the militia or to the 5th regt. of the line?
6. How many of the males upwards of 20 years of age are employed in agriculture, or in other arm servants, gardeners, or other?
7. How many of the males upwards of 20 years of age are employed in agriculture, or in other arm servants, gardeners, or other?
8. How many males upwards of 20 years of age are employed in manufacturing, or in making manufactures?
9. How many males upwards of 20 years of age are employed in retail trade, or in other capacity requiring skill in the shop?
10. How many males upwards of 20 years of age are employed in banking, capital, or other business, or in other capacity requiring skill in the shop?
11. How many males upwards of 20 years of age are employed in banking, capital, or other business, or in other capacity requiring skill in the shop?
12. How many males upwards of 20 years of age are employed in banking, capital, or other business, or in other capacity requiring skill in the shop?
13. How many household servants, including all female servants, and such male servants (of whatever age) as are not of taxable age, and attendants at inns, distinguishable from the males under 20 years of age?
14. If you have entered any males in answer to question 8, specify the manufactures in which they are employed, and what proportion of the number of these entered in answer to question 11 are employed in any quarry, mines, coal-pits, or public work in progress?
15. Referring to the number of persons in 1821, to what cause do you attribute any remarkable difference in the number at present?
16. Are there any other circumstances which you may think it necessary to remark in explanation of your answers to any of the preceding questions?

In answering this question, the males are to be carefully distinguished into three classes, viz., first, occupiers of land, who constantly employ and pay one, or more than one, labourer or farm servant in husbandry; secondly, occupiers of land who employ no labourer other than of their own family; thirdly, labourers in husbandry, and farm servants employed by occupiers of the first class.

8. How many males upwards of 20 years of age are employed in manufacturing, or in making manufactures?
9. How many males upwards of 20 years of age are employed in retail trade, or in other capacity requiring skill in the shop?
10. How many males upwards of 20 years of age are employed in banking, capital, or other business, or in other capacity requiring skill in the shop?
11. How many males upwards of 20 years of age are employed in banking, capital, or other business, or in other capacity requiring skill in the shop?
12. How many males upwards of 20 years of age are employed in banking, capital, or other business, or in other capacity requiring skill in the shop?
13. How many household servants, including all female servants, and such male servants (of whatever age) as are not of taxable age, and attendants at inns, distinguishable from the males under 20 years of age?
14. If you have entered any males in answer to question 8, specify the manufactures in which they are employed, and what proportion of the number of these entered in answer to question 11 are employed in any quarry, mines, coal-pits, or public work in progress?
15. Referring to the number of persons in 1821, to what cause do you attribute any remarkable difference in the number at present?
16. Are there any other circumstances which you may think it necessary to remark in explanation of your answers to any of the preceding questions?

The attempt made on this occasion to classify the population in respect of age, was limited to the division of males into those above and those below 20 years. At the enumeration in 1821 a question, regarding the ages of persons, was addressed in the following terms to the overseers and other persons employed: 'If you are of opinion that in making the preceding inquiries, the ages of the several individuals can be obtained in a manner satisfactory to yourself, and not inconvenient to the parties, be pleased to state. The numbers of those under 5 years—of those between 5 and 10 years—10 and 15—15 and 20—20 and 30, and so on in each following decenary period of life to the age of 100, adding further the number of persons above 100. It has

been cause for surprise, that notwithstanding the thus given, a very considerable proportion of the ages of males and females should have been obtained. That proportion in the different divisions of the kingdom was as follows:

In England	9,836,461	out of 11,361,437
Wales	700,210	717,438
Scotland	1,866,708	2,093,438
Ireland	6,793,230	8,801,330

United Kingdom . . 19,280,607 out of 20,873,661 or very nearly twelve out of every thirteen persons in the entire kingdom, while in Ireland there is a deficiency in this part of the statement of only one person in each 850 inhabitants.

CENTAUR, in mythology, a compound of horse and man, supposed to have sprung from the amour between Ixion and the Cloud, which he mistook for Juno: their name has been thought to point to their origin (*κεντ-ειν, αἰον-αυ*); but this explanation can hardly be admitted. It is not improbable that their existence may have been imagined from the first sight of a man on horseback, and as their history makes them neighbours of the Lapithæ, it is likely that they were merely one of those Thessalian tribes among whom the far-famed cavalry of that nation took its rise. They are also called Hippocentaurs. Pausanias' account of the origin of their name (*ἀπὸ τοῦ κεντρίν τοῦς ταύρους*) is a mere invention, and, in point of etymology, quite inadmissible.

The battle of the Centaurs and the Lapithæ forms the subject of the metopes of the Parthenon, part of which are now in the British Museum; and also one of the two subjects represented on the Phigalican frieze, which is also in the British Museum.

CENTAUREA, a very extensive genus of plants, belonging to the Cynaraceous division of Compositæ, but comprehending no species of any importance to man. *Centaurea Cyanus*, the common blue-bottle of corn fields, is sometimes cultivated for the sake of its many coloured flower-heads. Two others, *C. montana* (the purple, white sultan of gardeners), and *C. scaberrima* (yellow sultan), are occasionally seen among other annuals in gardens; but the greater part are to be found only in botanical collections many are mere weeds.

CENTAURUS, the Centaur, a southern constellation, a very small part of which rises in our latitude. It is situated under Virgo and Libra, and is evidently connected with LUPUS and ARA. From Ptolemy's catalogue, it is evident that he considered the Centaur as holding the wolf (or wild beast, as it is called) in one hand, and a thyrsus in the other; and from the proximity of the altar, it is plain that a sacrifice is alluded to. According to Grotius (notes on Aratus), the thyrsus antiently had a hare hanging from it. In some older figures, the Centaur holds a spear in both hands, which sustains the wolf, passing through its head. Hyginus makes only one constellation of Centaurus and Lupus.

CENTIGRADE means divided into one hundred degrees. The centigrade thermometer of Celsius divides the interval between the freezing and boiling points into 100 degrees. Thus 100 centigrade degrees are equivalent to 180 of Fahrenheit; and to turn the reading of a centigrade thermometer into that of Fahrenheit, proceed as follows:—Multiply by 2 and 20, subtract, divide by 10, and add 32. Thus for 78° centigrade.

CENTIVRE. [SCOLEPENDRA.]

CENTIVRE, SUSANNA, was the daughter of a Lincolnshire gentleman named Freeman, who, being a dissenter and zealous parliamentarian, was compelled, upon the restoration of Charles II., to seek refuge with his wife in Ireland, in which kingdom it is presumed that Susanna was born, about the year 1680. At three years she lost her father, and before she had attained her thirteenth year, she was left by the death of her mother completely an orphan, and according to some accounts utterly destitute. As the scandalous story which Whincop relates of her does not appear to have any foundation in fact, we gladly pass over it, and come at once to her marriage at the early age of sixteen to a nephew of Sir Stephen Fox. A twelvemonth had scarcely elapsed before death deprived her of this new protector. But the wit and the beauty which had probably been the only dower she brought the first, soon procured her a second husband, an officer of the name of Carrol, to whom she appears to have been much attached. About a year and a half after the marriage, this gentleman had the misfortune to be killed in a duel, and Mrs. Carrol became a second time a widow. In this state of desolation and distress she first applied to her pen, as well for support as for the amusement of her lonely hours, and several of her early productions were published under the name of Carrol. Among the first was a tragedy, called 'The Perjured Husband'; but the natural bent of her genius being towards comedy, we find but one more serious drama amongst the nineteen which bear her name. Such was her attachment to the stage, says her biographer, that she became herself a performer, but her success does not seem to have been great, and her stay in it was of short duration. In 1706, while sustaining the character of Alexander the Great, in *Leo's Rival Queens*, at Windsor, where the court then was, she won the heart of Mr. Joseph Centlivre, Yeoman of the Mouth, or Principal Cook to Queen Anne, and eventually married him. They lived happily together for some years, and she died at his house in Spring Gardens, December 1, 1723, at the age (if the time of her birth be rightly stated) of forty-three. Of her dramatic works, an alphabetical list is given by Baker in his 'Playhouse Companion'; but only three out of the nineteen there enumerated keep possession of the stage:—'The Busy Body,' 'A Bold Stroke for a Wife,' and 'The Wonder.' The first was greatly objected to by the actors, and Mr. Wilks for some time refused to play in it: even the audience came prejudiced against it to the theatre. The second was also pre-condemned by Wilks, who is reported to have said, coarsely enough, that 'not only would her play be damned, but she herself for writing it.'

CENTRAL AMERICA comprehends the countries which, under the dominion of Spain, were known by the name of the kingdom of Guatemala. It forms the central portion of the long isthmus which unites North and South America, and extends from 8° to 18° N. lat., and from 82° to 94° W. long. Its greatest length from S.E. to N.W. may be about 1000 miles; its breadth varies from 100 to 300 miles.

Humboldt, in 1811, estimated the surface of Central America at 26,152 French square leagues, or 198,765 square miles; but in 1822 he reduced it to 16,749 leagues, or 127,224 square miles. Dunn allows 22,000 square leagues, or 167,200 square miles. This last statement does not differ much from the first of Humboldt, because the state of Chiapa, which contains about 36,000 square miles, had in the meantime

been separated from Central America. The estimate of Dunn may probably have been made with a certain degree of accuracy; but it depends on old maps and charts, and the numbers are somewhat too large. In 1822 the eastern shores of Central America were surveyed by Commodore Owen, who ascertained that the coast south of Cape Gracias á Dios had been laid down in the charts from 25' to 30' too far to the east. This diminishes the surface of Central America by 8000 or 9000 square miles. Supposing the average width of the country to be 150 miles (which is perhaps near the truth), and its average length 1000 miles, we obtain an area of 150,000 square miles, or the extent of the British Islands and about one-third more.

Its boundary is mainly formed by the Atlantic Ocean on the E. and N.E., and by the Pacific on the S.W. At its south-eastern point it borders on the republic of New Granada, on the department of Isthmus; the line of separation runs from Cape Buena on the Pacific nearly due north to the Atlantic, a few miles west of the Laguna de Chiriqui. Its most northern part extends between the British settlement of Balize and the United Mexican States; the boundary line between the republic and the neighbouring countries has not yet been exactly determined. It is still asserted in nearly every geographical work that the Andes continue through the Isthmus of Panama, and that the elevated Cordilleras of Peru and New Granada are connected with the Rocky Mountains of the United States by a continuous range; but this conveys an erroneous idea of that portion of America. Properly speaking, there is no elevated mountain-range between 7° N. lat., where the Andes terminate, and 33° N. lat., where the Rocky Mountains begin, at least not such a range as can be compared with the Andes in South, or the Rocky Mountains in North America. The Andes of South America terminate as it seems abruptly at near 7° N. lat., and are followed by a plain which, extending through the Isthmus of Panama, terminates W. of the Bay of Parita. This plain, following the nearly semicircular bend of the isthmus, is about 280 miles in length. The south-eastern half of it, contiguous to the northern extremity of the Andes, appears to be a level tract, very little elevated above the sea. The western half is partly hilly and partly level; but the high lands which extend between the Bay of Managua and the mouth of the Chagre for 90 miles, probably nowhere rise to more than 1500 feet; their direction is due east and west, and consequently perpendicular to that of the Andes. They are followed by another low plain, on which some isolated hills rise about 500 feet above it.

The second section of the isthmus extends from the Gulf of Parita to the country which lies between the Gulf of Nicoya and the mouth of the Rio de S. Juan. It is about 280 miles in length. This part of the isthmus is nearly unknown, not having been visited by Europeans. According to the prevailing opinion it consists of a mass of mountain-rocks, about 2000 or 3000 feet high, which contain some extensive plateaus and a few peaks, mostly of volcanic origin. Between 10° 30' and 13° N. lat. extends the plain of Nicaragua, which is about 175 miles long from south to north, and nearly as much from east to west. It is very little elevated above the sea, the lake of Nicaragua, which covers a considerable portion of it, being only 131 feet above the Pacific. It is separated from the Pacific by a range of low volcanic hills, very few of which rise to more than 700 feet above the sea. The country which lies between this plain and the southern coast of the Gulf of Honduras, and terminates on the west at the Isthmus of Chiquimula, is very little known. Its eastern portion, up to the meridian of 85°, is probably a low plain, with hardly a hill upon it. The western part is a hilly country, traversed by several (at least four) ridges, running west and east. The intermediate valleys open in general to the east, and most of them terminate on the eastern plain. The northern and southern ridge are best known. The northern ridge, running along the Gulf of Honduras, rises perhaps to the mean height of 3000 feet, but declines towards the eastern extremity, not far west of the Rio Patook. The mountain of Omoa is 7000 feet high, and that of Congrebo 7500 feet. The southern ridge divides the waters which flow to the Pacific from those which fall into the Atlantic. It contains any considerable elevation in a few isolated volcanic peaks. It seems to be rather a table-land of uneven surface, and of little width, though of great extent. The intermediate ridges are entirely unknown.

The Isthmus of Chiquimula extends, on the Atlantic, from the mountains between Omoa and the mouth of the Rio Motagua to the innermost corner of the Gulf of Honduras; and on the Pacific, from the harbour of Acajutla to the mouth of the Rio Esclavos. At less than 20 miles from the Pacific there is a broad-backed range of high ground, a continuation of the southern range of the hilly country of Honduras, which unites Honduras to the table-land of Guatemala. The country north of this range is traversed by high and steep hills running east and west, and so closely united to the table-land of Guatemala that they must be considered as offsets of it. The valleys between them are commonly of moderate width and low. The distance between the two oceans, across this isthmus, is about 150 miles.

The table-land of Guatemala occupies all the countries between the isthmus of Chiquimula and that of Tehuantepec in Mexico; the high land in the interior of the peninsula of Yucatan forms its north-eastern projection. Near its southern borders, about the town of Guatemala, it is nearly 5000 feet above the sea; and this may be considered as the mean height of that portion which is south of the Rio Motagua. But north of this river the country rises higher. The most elevated part of it appears to lie between the towns of Totonicapán and Gneguetenango ($15^{\circ} 30' N.$ lat.) From this point it begins to lower gradually, and its north-western edges, which belong to the Mexican State of Chiapas, are indented by deep and sometimes wide valleys. No continuous range of any considerable elevation traverses this plain, the surface of which is slightly undulating, like the central parts of England; but here and there it is traversed by a range of hills, about 200 or 300 feet above the plain. The descent from this plain to the low shores of the Pacific is extremely steep, and consequently when seen from that side it has the appearance of a mountain-range, an illusion which is confirmed by a few lofty volcanoes standing near the edge of this descent. The most remarkable are the two volcanoes of Guatemala, situated to the north-west of the town of New Guatemala, of which the Volcano de Agua (or water volcano), according to Col. Galindo, is 12,620 feet high, and the Volcano de Fuego (the fire volcano) somewhat higher. The low country between the Pacific and the table-land, which rises above the plain like a wall, is very level, and measures from 20 to 30 miles across. The eastern border of the table-land, by which it descends to the Gulf of Honduras, is not so distinctly marked, being cut by deep valleys, between which the high land takes the shape of ridges, which extend to a great distance, and in some places, as between the Rio Motagua and the Golfo Dulce, advance to the very shores of the sea. The country between the table-land and the Gulf of Honduras may therefore be considered as a succession of valleys and ridges, except the part to the west and north-west of the Golfo Dulce, which is a low plain.

The difference in the elevation of the surface, which in Central America is perhaps greater than in any other country of equal extent, or at least varies more frequently, produces a corresponding difference in the climate and productions of the natural divisions of the country. The great plain of Nicaragua, with that to the north of it, on the shores of the Caribbean Sea, is only wooded along the rivers. Between the rivers, and along the coast, it forms extensive savannahs, covered with a rich verdure, and presenting occasionally a clump of high trees. The low hills, however, which rise on it, are mostly wooded, especially on their declivities. The climate of these plains being excessively hot and moist, the Spaniards have not formed any settlements on this extensive tract, and it is only inhabited by independent aboriginal tribes. The low plains along the Pacific average from 20 to 30 miles in width, west of the Rio Esclavos; but east of it, only from 10 to 20, or even less: they are covered with an uninterrupted forest of high trees, many of which furnish valuable timber and dye-woods. The heat is excessive, the thermometer rising frequently to 90° and higher, but the climate is considered much more healthy. European settlements are very rare, and the scanty population is almost entirely composed of Indians.

As in other parts of Spanish America, the European settlements have been formed on the high table-lands. That of Guatemala is nearly without trees, and even bushes, except on the declivities of the hilly ranges, which traverse it in every direction. Its climate is that of an eternal spring; the thermometer during the whole year scarcely varies. The average temperature in the middle of the year may be considered to

be from 68° to 70° ; but during the north-west winds it sometimes, though rarely, descends 20° within a few hours. The hilly districts, whose highest ridges rise to the elevation of the table-land only in a few isolated peaks, have a more variable climate. In the valleys, along the Atlantic, there hardly passes a day without rain. They are nearly uninhabitable by Europeans, and even the Indians are far from being numerous; but they display the whole vigour of a tropical vegetation, being clothed with numerous species of trees, shrubs, and plants. Those valleys in which the air of the sea is intercepted by ranges of hills are less damp, and more habitable, but their fertility is not so great. This is particularly the case with the valleys of Honduras.

On the table-land, and in the districts not contiguous to the Caribbean Sea, the dry season begins about the close of October, and lasts until the end of May; during which time only a few showers occasionally refresh the air. In the beginning of June thunder is frequent, and is followed by long and heavy rains. But even during this time it rains only in the evening and the night; from six o'clock in the morning till three or four o'clock in the afternoon, no cloud passes over the sky, and the air is dry and pleasant. Towards the middle of October the north winds set in with frequent thunderstorms, and after them the dry season begins.

The north winds (*los nortes*) prevail during the whole of the dry season, and then, in the months of November and December, thin ice is formed on the highest portion of the table-land, and snow falls on the most elevated peaks. These winds blow with considerable force, and seem to pass over the isthmus, and to produce the north-eastern and north-north-eastern winds, which render the access to the shores of the Pacific difficult and dangerous during the dry season. On this coast they are called *Papagallos*. Towards the end of the rainy season, in the months of August and September, the same coast is subject to violent storms from the south-west, called *Tupayaguas*.

Few countries, even in South America, are so subject to earthquakes, and contain so great a number of volcanoes. Many of the hills between the lake of Nicaragua and the Pacific are volcanoes, and most of them are active. The number does not decrease to the north-west of the lake, several of them occurring on the southern and eastern shores of the bay of Conchagua. In this district, which is hardly more than 180 miles in length, above twenty volcanoes are known to exist. Farther to the north only isolated volcanoes occur at considerable distances from one another, on the edge of the table-land. There are also a few volcanoes on the south-east of the lake of Nicaragua. Earthquakes are most frequently felt on the table-land, where they occur annually at the setting in of the northern winds, but the most violent take place at the end of the dry or the beginning of the rainy season. Old Guatemala was almost entirely destroyed by an earthquake on the 29th of June, 1773, and New Guatemala suffered very much on the 23rd of April, 1830.

The table-land and most of the hilly districts are considered very healthy. The goitre is common, especially among the mixed race, and here, as in Switzerland, it is often attended with idiocy. The whole of the shore of the Caribbean Sea is very unhealthy: malignant fevers prevail there all the year round, owing to which these extensive tracts are very thinly inhabited. The low plain along the Pacific is much more healthy.

The river S. Juan falls into the Caribbean Sea, near $11^{\circ} N.$ lat. It was till lately supposed that, by means of this river and the lake of Nicaragua, an easy communication could be opened between the Atlantic and Pacific; but the difficulty of effecting this communication appears to be great, though not insuperable. The river S. Juan is only the channel by which the lake of Nicaragua discharges its waters into the Atlantic. The lake or lagoon of Nicaragua is an inland sea, of a lengthened form, being about 120 miles long and 40 broad where widest, without narrowing much at either end. Its circuit is near 400 miles. It is deep enough to be navigated by vessels of considerable size, having at some distance from the shores from six to twenty fathoms of water along the southern and western banks. It is only very shallow along the north-east shore for a mile and upwards into the lake. It contains several islands, among which that of Ometepe, near the south-western bank between Granada and Nicaragua, is remarkable for a high volcano, and for its fertility and great population, being in-

by 3000 or 4000 Indians. The river issues from the extremity, and near the fortress of S. Carlos it is 100 feet broad, and from six to seven deep. About the middle of its course the S. Juan receives from the south Rio S. Carlos, and flows down the Serrapit. About 20 miles from its mouth the river divides into two, of which the southern and wider is called Rio Col.

It then enters the sea near the harbour of S. Juan de Nicaragua. The depth of water in the upper part of the course of the river varies from nine to twenty feet, but in some places it is so shallow that rapids are produced. The greatest of these rapids is about 28 miles from the lake. The lower portion of the river, below its bifurcation, is generally very shallow: at many places during the dry season there are not more than two feet of water. The port of S. Juan de Nicaragua is not considered very unhealthy, and the harbour is deep enough for merchant vessels, and safe; but up to the present time it is nearly uninhabited. The most north-western mouth of the river, which is the only one that can be used, has a bar with only two or three, and seldom four, feet water upon it. Huefkens is of opinion that the cutting of a canal through the plain from the port of S. Juan to the lake of Nicaragua, would be less expensive than to make the river navigable. He estimates the distance in a straight line at less than 60 miles. The winding course of the river amounts to 120 miles. Other obstacles present themselves to the attempt of uniting the lake of Nicaragua with the Pacific by a canal. The difference of level between the lake and the sea is 134 feet, and therefore locks would be necessary. Two places seem to offer peculiar advantages for such a canal: the narrowest portion of the isthmus which separates the lake from the Pacific is between the town of Nicaragua and the port of S. Juan del Sul, where it is only 15 or 16 miles across; but the hills upon it rise to between 400 and 500 feet. The hills might perhaps be avoided, but the canal would of course be longer. Some persons think that it would be more advantageous to unite the lake of Managua by a canal with the harbour of Realejo. The country between them is nearly level, and of a firm soil, without being rocky. Besides this, the canal would terminate in the port of Realejo, one of the best harbours on the west coast of America, while that near Nicaragua would end in the harbour of S. Juan del Sul, which is small and unsafe. But this canal would be more than twice as long as the other, and, in addition to this, the Tepitapa, which unites the lake of Nicaragua with that of Managua, must be rendered navigable. The lake of Managua is 150 miles in circumference, 35 miles long, and 15 broad in its widest part. It is deep enough for vessels of considerable size; but the Rio Tepitapa, which brings down the water from the lake of Nicaragua, and is about 25 miles long, has falls which, in the dry season, are from six to eight feet high, and also several shoals. These obstacles seem to have been produced by the lava, which, in 1722, ran from the neighbouring volcano of Managua into the river, and it is supposed that they could be avoided by a canal cut through the level ground on the northern side of the Rio Tepitapa. There is even now a navigation between the town of Granada on the banks of the lake of Nicaragua and the port of S. Juan de Nicaragua, on the Atlantic. Flat-bottomed river-barges are used for the transport of goods, and accomplish their voyages in eight or ten days.

The most important river of Central America is the Rio Dulce, the channel by which the Golfo Dulce discharges its waters into the Gulf of Honduras, 15° 25' N. lat. The Golfo Dulce is a fresh-water lake, about 50 miles in circuit. On its southern banks is the small town of Yzabal, which in some respects may be considered as the principal port of Central America, most of the European goods designed for that market being brought to it by vessels, and thence transported to the interior on mules. The Rio Dulce, issuing from the eastern portion of the lake, turns to the north, and expands into a small lake, called the Golfetta (the small gulf), about 10 miles in width. This river, which is about 20 miles long, has a considerable depth, except on its bar, where there are only six or seven feet water, so that large vessels cannot go up to Yzabal.

The Rio Polochin enters the Golfo Dulce from the west. This river rises on the table-land of Guatemala, but soon descending into a wide and deep valley, it becomes navigable at the Encarnadero de Telemán, a considerable distance from its mouth. It is a rapid river, and deep enough for vessels drawing several feet of water, but on the bar at its mouth there are only three or four feet of water. Still it

is thought that if a road were made from Telemán to the town of Guatemala, the expense of the transport of goods would be considerably diminished.

The Motagua rises likewise on the table-land of Guatemala, close on its western border, and runs through it in an easterly direction, till it descends from it some distance W. of Zacapa. At Gualán, some miles farther down, the river becomes navigable, but owing to its numerous rapids and shoals, it can only be navigated by boats not drawing more than 1 or 1½ foot water. Towards its mouth the river turns to the N.E. and falls into the Gulf of Honduras about 15 miles W. of Omoa. By means of this river a considerable quantity of European goods, especially the heavier kind, are sent into the interior of Guatemala; they are transported from Gualán to the places of consumption on mules.

East of the mouth of the Motagua several smaller rivers (the Chamalecon, the Ulua, the Amone, the Lean, &c.) fall into the Gulf of Honduras, some of which are navigable for small boats for several miles. E. of Cape Camaron is the mouth of the Black River, or Rio Tinto, and still farther E. that of the Patook, both of which drain a considerable country; they run from W. to E. in the interior, where the Rio Tinto is called Rio Paon and the Patook Rio Guayape. The latter is navigable for a considerable distance, but the navigation does not extend to the mouth, the low country along the coast being occupied by Indian tribes, who have no intercourse with the inhabitants of the republic. The same observation applies to the Wanks, or Rio de Segovia, which empties itself into the sea near Cape Gracias á Dios, and to the River Blowfields, whose mouth is about a degree north of that of the S. Juan. Both are considerable rivers, draining large tracts, but this is all that we know about them.

The rivers which fall into the Pacific have all a short course. The largest is the Lempa, which is of considerable depth, and so rapid that it is entirely unfit for navigation. A bar at its mouth hinders even vessels of moderate size from entering it. The little river Michatoyat forms a small harbour at its mouth, which is considered as the port of the town of Guatemala, on the Pacific, and is called Barra de Istapa, or at present Puerto de Independencia. On the northern portion of the table-land of Guatemala runs the Usumasinta, a river of considerable length, which is not navigable within the boundary of Central America. It runs northwards, and enters the state of Tabasco, which belongs to the Mexican Union, where it is navigable and unites with the Rio Tabasco.

The lake of Peten, situated in the most northern district of Central America on the table-land of Yucatan, is of an oval form and about 70 miles in circuit. It contains several islands, on the largest of which is a small fortress, used as a prison. The lake of Atitán is 80 miles N.W. of the town of Guatemala, and near the western edge of the table-land. It is about 18 miles long and 9 broad, and remarkable for its extraordinary depth and for having no outlet, though several small rivers fall into it. In its neighbourhood is a volcano, which, in 1822, made a violent eruption. The lake of Guixar, N.W. of the town of S. Salvador, has a circuit of about 80 miles; it is said to communicate by a subterraneous channel with the much smaller lake of Metapa. The lake of Guixar is one of the principal feeders of the Rio Lempa. Along the low shores extending from Cape Camaron to the mouth of the Rio S. Juan there are many lagoons of considerable extent, which are separated from the sea by narrow, and low strips of land. Some of them, as the Carataska lagoon, are above 10 miles wide and 3 or 4 times as long. They communicate by narrow outlets with the sea, but the water is not deep enough to admit small vessels. Most of them are imperfectly known.

The natural fountains, called geisers, have hitherto been supposed to exist only in Iceland, but Huefkens states, that there is a fountain of this kind on the table-land of Guatemala, not far from the town of Quezaltenango. A large mass of boiling-water is thrown up to the height of 20 or 30 feet.

The objects of agriculture differ considerably, according to the difference in the elevation of the soil. Wheat is raised almost exclusively in the most elevated districts of the table-land of Guatemala, and also in some districts in the hilly country. It does not seem to grow much below 5000 feet. In the same districts barley is cultivated, with potatoes, and some of the European vegetables. The most common fruits are apples, pears, peaches, grapes, &c. where the table-land does not rise much above 5000 feet, nor near

Below 4000, in the neighbourhood of the town of Guatemala, there are extensive plantations of nopal trees for rearing the cochineal insect. Below 3000 feet, indigo, cotton, sugar, and tobacco are the chief crops, and on the low coast along the Pacific cacao is cultivated. The kinds of grain grown here most abundantly are rice and maize, but there are also large plantations of sesamum for obtaining oil, and of maguay, for the preparation of *pulque*, an inebriating drink. Maize is indeed grown all over the country. In the colder regions only one annual crop can be got; but in the warmer districts, where it yields from 150 to 300 return, two or three crops may be obtained, though the ears are smaller and the grain does not keep so well. Mandioca is not so much cultivated as the banana. The different leguminous vegetables, as beans, kidney beans, *branzas*, or Spanish peas, lentils, &c., are to a certain extent spread over the whole country. Capsicum is extensively used instead of salt. The fruits of the warmer districts are merely pine-apples, yucas, sapotes, jocotes, anonas, oranges, &c. The agricultural products for exportation are indigo, cochineal, tobacco, cotton and sugar. Indigo is chiefly planted in the hilly country along the Pacific, between 80° and 90° W. long., in the state of Salvador. It is of excellent quality, and formerly 1,000,000 pounds were annually exported, but of late the continual civil wars have much reduced its cultivation. Cochineal is gathered in the neighbourhood of the town of Guatemala, and the quantity which some years ago was exported amounted to 100,000 lbs. Excellent tobacco is grown in the hilly districts, but no great quantity is exported, owing to the government having limited its cultivation to certain places and to a certain amount. The cotton grown along the Pacific is of excellent quality, but is always sent to foreign markets in an indifferent state, as the cultivators are not acquainted with the best methods of rearing it from the seed. Sugar is cultivated along the Pacific, but the quantity exported to Peru and Chile and sometimes to Mexico does not exceed 3000 or 4000 hundred weight. The cacao of Soconusco, the most western district on the Pacific, was a century and a half ago considered the best in the world, and reserved by the Spanish court for its own use. Other contiguous districts also produced and exported considerable quantities of this article; but, for some reasons not very well known, this branch of agriculture has decreased so much that cacao is imported from Guayaquil for the consumption of the country. Mahogany-wood, sarsaparilla, vanilla, and the black balsam, known under the name of Peruvian balsam, are also exported. Gold, silver, copper, and iron are found in several places in the hilly districts, and some mines are worked. Jasper and marble occur also. Brimstone of good quality is collected in the neighbourhood of certain volcanoes on the table-land, and salt is made along the Pacific, west of 90° W. long.

Cattle is abundant, particularly in the interior valleys of the hilly districts of Honduras, and along the north-eastern banks of the lake of Nicaragua. Hides and jerked beef, as well as live stock, are exported. The horses are small, but handsome and hardy. Sheep are only reared in considerable numbers on the table-land of Guatemala, where the wool, which is rather coarse, is used for the manufacture of Quezaltenango, &c. Hogs and poultry abound, and are of good size and quality. Mules are very numerous, their consumption in the country itself being very great, as they are generally used for the transport of goods. Among the wild animals are numerous tribes of parrots, mackaws, and monkey. The quetzal, one of the most beautiful of the feathery tribe, is only found in Central America. The manati is seen at the mouth of the S. Juan, where also, as well as in the lakes of Nicaragua and Managua, alligators are common.

The population of Central America consists of aboriginal tribes, of the descendants of Europeans, and of the mixed race or the offspring of Europeans and Indians. Several Indian tribes still live in a state of perfect independence, and nearly without any intercourse with the Europeans. These tribes occupy the whole of the eastern coast from the boundary of New Granada to Cape Camaron, and the country inland for 20, 50, and even 60 miles. Probably not less than one-eighth of the republic is in their possession. Some of these tribes, known by the name of Mosquito Indians, who occupy the coast from the mouth of the Patook river to Cape Gracias á Dios, and farther south, consider themselves placed under the protection of Great Britain. These tribes do not wander about, but derive their main subsistence from the cultivation of the ground. Other

Indian tribes, who were subjected by the Spaniards, have now obtained all the rights of free citizens of the republic. These Indians are very numerous on the table-land of Guatemala, where they constitute the bulk of the population. They speak different languages, among which the Quiché and Catechiquel are the most extended. Their principal occupation is agriculture, but some of them are also employed as workmen in the manufactures. In many parts they seem to enjoy a degree of comfort and to live in easy circumstances; in others they are extremely miserable. The whites are the descendants of Spaniards, who have settled in this country since its conquest in 1524. They are dispersed over the whole of the country, but in none of the states do they form a majority, except in Costarica. The mixed race, in other parts of America known under the name of *Mulattos*, are called in Central America *Ladinos*. They are pretty numerous all over the country, but most so in the States of Salvador, Honduras, and Nicaragua. They are the most active portion of the population, and follow the different trades of shopkeepers, mechanics, muleteers, &c., and are frequently in easy circumstances. No recent census has been taken, but it is probable that the whole population is between 1,500,000 and 2,000,000, in which however the independent tribes are not included, their number being entirely unknown. It is supposed by Hæfkins that the whites form one twelfth, the *Ladinos* four-twelfths, and the Indians seven-twelfths of the whole population.

The manufactures in Central America, though they have much decreased, are still important. Till the Spaniards lost their dominion in this country, nearly all the cotton and woollen goods consumed in it were made here. In 1795 there were more than 1000 looms for cotton goods in the town of Old Guatemala. This branch of industry has much decreased, owing to the free importation of English goods. The manufacture of woollen goods have not suffered to the same extent; the *chamurras*, a kind of black cloaks, are still made to a large amount at Quezaltenango and Totonicapán, where there are still some manufactures of coarse cotton goods, coarse woollen cloth, and common hats. It is conjectured that the annual value of the manufactured goods made in the northern districts of the table-land of Guatemala and exported to the other states, does not fall short of 200,000 Spanish dollars. There are manufactures of crockery, coarse furniture, and wooden utensils. In the town of Granada, in Nicaragua, four-post bedsteads of great beauty are made of the different kinds of wood peculiar to that country. They are not only sent to the other states, but also to the West Indies.

The United States of Central America are Guatemala, Salvador, Honduras, Nicaragua, and Costarica.

I. Guatemala comprehends the most northern portion of the republic, and the whole of the table-land of Guatemala, with the hilly country between it and the Gulf of Honduras, and the low tract which divides the table-land from the Pacific. The greatest part of the isthmus of Chiquimula also belongs to it. In this state all the cochineal, sarsaparilla, and vanilla are gathered, which are exported from Central America, and a great deal of mahogany is sent to Balize. In its most northern district, near the lake of Peten, there are still a few Indians in a state of independence. It is divided into seven departments, Verapaz and Peten, Chiquimula and Zacapa, Guatemala and Esquintla, Sacatepeques and Chimaltenango, Solola and Suchetopeques, Quezaltenango and Soconusco, Totonicapán and Gueguetenango; and contains, besides the two capitals, New and Old Guatemala [GUATEMALA], the following places:—

Quezaltenango, on the table-land, not far from its western border, in a country nearly surrounded by volcanoes, contains a population of 14,000, mostly Indians, and the most considerable manufactures in wool and cotton.

Totonicapán, farther east, has 12,000 inhabitants, mostly Indians, and likewise manufactures in wool, wood, and crockery.

Cobán, near the eastern border of the table-land, in a very beautiful valley among groves of fruit-trees and plantations of bananas and sugar, contains 12,000 inhabitants, all Indians.

Gualán, a small town with about 2000 souls, is the place where the goods brought from the coast are barged up the river Motagua are to be unshipped to be transported on mules into the interior.

On the table-land several other places occur, whose population, consisting mostly of Indians, in many instances

amounts to 8000, 8000, and even 12,000 souls. The low tract along the Pacific is very thinly inhabited, and still less so the hot and rainy valleys near the Golfo Dulce and the Gulf of Honduras.

There are two harbours in this state. Yacual, on the Golfo Dulce, consists of about fifty or sixty huts, with 200 or 300 inhabitants, and is the depot of the European merchandise. On the Pacific is the port of Independencia, at the mouth of the river Michatoyat, inhabited by a few men. It is an open and unsafe roadstead.

II. Salvador extends along the Pacific from 88° to 90° W. long., and from 40 to 50 miles inland. It is the most populous part of Central America; even the shores of the sea, which are bordered only by a narrow, level, and low tract, are commonly well inhabited. Nearly all the indigo exported from Guatemala is grown here, besides sugar and cotton. The Peruvian balsam is collected in the forests. There are mines of iron. It is divided into four departments, S. Salvador, Sonsonate, S. Vicente, and S. Miguel, and contains several towns besides the federal district, with S. Salvador, the capital of the republic. [SALVADOR.]

S. Vicente, the capital of the state, contains about 8000 inhabitants. In its neighbourhood are extensive plantations of indigo, and near the village of Istepeque excellent tobacco is grown, which is known under that name all over Central America.

S. Miguel, farther east, has about 8000 inhabitants, and is noted for its fairs, of which the most important is held in November after the indigo crop.

Sonsonate, near the western extremity of the state, has a population of about 7000, and some commerce by means of the port of Acajutla, which exports sugar to Peru and Chile. The Indians inhabiting the country about the town make very beautiful mats, which are also exported. In the neighbourhood of Sonsonate is the Lago, a very active volcano.

S. Anna, situated at a considerable elevation above the sea, has 10,000 inhabitants; in its neighbourhood are iron mines, which formerly afforded an annual produce of seventy-five tons, but at present hardly one-third of that amount.

This state has four harbours—Acajutla or Sonsonate, Libertad, Iquileco or Triunfo de los Libres, and Conchagua or Union. Except the last, which is on the west shore of the Bay of Conchagua, and is extensive and safe, these harbours are, properly speaking, only open roadsteads, hardly accessible during the rainy season and the prevalence of the S.W. winds.

III. Honduras comprehends the greater portion of the hilly region. On the S. it extends to the Bay of Conchagua, and along the Gulf of Honduras, from near the mouth of the Motagua to Cape Camaron. Politically, also, the whole country of the independent Indians, extending from Cape Camaron to Cape Gracias á Dios, and hence to the mouth of the Rio de S. Juan, is included in this state. It exports annually about 40,000 head of cattle to Guatemala. Its mines are the richest and best known in Central America. The most important are those of Mount Merendon, between Chiquimula and the coast, and of Oloncho and of Corpus, near the boundary of Nicaragua. The latter are worked by Englishmen, as well as those of Tabasco, near the boundary line of Salvador. Their annual produce is not known. Jasper, opals, and marble occur in some places. The population is concentrated in the interior valleys, the coasts on both seas being nearly uninhabited. This state is divided into seven departments, Comayagua, Tegucigalpa, Choluteca, Oloncho, Gracias, Yoro, and S. Barbara. In the interior are few considerable places, and on the coast the harbours of Omoa and Truxillo.

Comayagua (Valladolid), the capital, is situated in a fine but unhealthy valley, at nearly an equal distance from the ports of Omoa and Truxillo, and contains 3000 inhabitants.

Tegucigalpa contains from 8000 to 10,000 souls, and has in its neighbourhood mines of gold, silver, copper, and iron. It is at a considerable elevation above the sea.

Omoa, on the Bay of Honduras, 13° 38' N. lat. and 88° 5' W. long., twelve or fifteen miles from the mouth of the river Motagua, is a small place but much frequented; the harbour, which is formed by a small bay, is very good. The goods imported from Europe or America are sent by barges to Guadalupe, on the banks of the Motagua.

Truxillo, farther to the E., is only a roadstead in an open bay, which formerly carried on an active trade with Havana, but it now exports only mahogany and a few hides, with a small quantity of soapstone and tortoiseshell to Bahia.

IV. Nicaragua comprehends the most southern portion of the hilly region, about the sources of the rivers Wanks and Blewfields and the volcanic country which separates the lakes of Managua and Nicaragua from the Pacific, lying between the Bays of Conchagua and Nicoya, besides that portion of the plain of Nicaragua which is contiguous to the Rio de S. Juan. The plain is nearly uninhabited; the hilly region is thinly inhabited, but the volcanic country is comparatively populous. No part of Central America is well peopled except the volcanic districts, which form a long narrow tract, extending from the southern extremity of the lake of Nicaragua (10° 45' N. lat.) to the towns of Quezaltenango and Totonicapán (15° 10'). Indigo, sugar, wood, and hides are exported from Nicaragua. Near the town of Nicaragua are the most extensive cacao plantations in Central America. Along the coast pearls are found, and in the Gulf of Nicoya the purple muscle, which is used in dyeing cotton yarn. In the most northern portion of this state are some mines of gold and silver, but they are not much worked. Nicaragua is politically divided into four departments,—Leon, Granada, Segovia, and Nicaragua.

Leon, the capital of Nicaragua, contained not many years ago a population of 32,000 inhabitants, but the civil contentions within the town have reduced it to half that number. It is situated on the road which leads from the best cultivated districts of the state to the harbour of Realejo.

Managua is a considerable place, containing 14,000 inhabitants.

Masaga has likewise a population of 14,000 souls, nearly all Indians, who are engaged in commerce with the adjacent populous country.

Granada, on the lake of Nicaragua, carries on some trade with Jamaica by means of the river and harbour of S. Juan. Population, 15,000 inhabitants.

Nicaragua contains, with the suburb S. George, 22,000 inhabitants, and is surrounded by a district noted for its fertility, especially in cacao and grapes.

On the coast of the Pacific are some good harbours, as Nicoya and Culebra. The harbour of Realejo, which is large and safe, exports the produce of the state to the other states, and to Peru and Chile; to which last-named countries mahogany, cedar wood, and Nicaragua wood are sent.

The harbour of S. Juan, at the mouth of the river of that name, is nearly uninhabited.

V. Costarica comprehends the western part of the high land which divides the plains of Panama from those of Nicaragua. It is only inhabited in its western districts; those bordering on the republic of New Granada are either uninhabited or in possession of independent Indians. Sugar, timber, and Indian corn are exported to Peru and Chile. Some mines of gold are worked. The most important are those of the mountains del Aguacate and of Real del Monte. Costarica is divided into two departments, Oriente and Occidente.

S. José, the capital, contains about 16,000 inhabitants.

Cartago, the former capital, has an equal population.

Acajutla is inhabited by 10,000 souls. This state contains two harbours. On the eastern coast of the Gulf of Nicoya is Punta de Arenas, in which vessels not drawing not more than nine or ten feet of water can enter. Matina on the Atlantic is a small and unsafe port.

The commerce of Guatemala is considerable, but it is difficult to form an estimate of it for want of exact information. Haefkin estimates the value of all goods imported at 900,000 Spanish dollars, and the exports at the same amount. He adds, that the exports were at least double that sum during the Spanish dominion. Thompson, on the other hand, thinks that the trade has considerably increased since the country has gained its independence. He states, that according to a rough account the English goods imported (in 1825, or shortly before), by way of Bahia and Jamaica, amounted in value to 1,995,605 $\frac{1}{2}$ sterling, and that goods to the amount of 2,500,000 $\frac{1}{2}$ were returned to those two places. According to his opinion, the English goods brought to Central America, formed about one half of the whole imports, and consequently all the goods imported into that country must have amounted to nearly 7,000,000 $\frac{1}{2}$ sterling. The imports from Britain consist chiefly of broad cloth, cotton goods, hardware, and other dry goods. The Spanish and the French have the principal trade in silks, glass trinkets, wines, and spirits. Great quantity of grapes and other China goods are brought in American vessels to Acajutla.

The finances of Central America have deranged

ever since the country obtained its independence, when the capitation tax on the Indians was abolished, and no taxes imposed to cover the deficit thus arising. The expenses in 1825 amounted to 652,608 Spanish dollars, but the revenues assigned to pay them produced only 471,359 dollars, so that the remainder, amounting to 181,249 dollars, was to be paid by the single states. The debt to England amounts to about 1,500,000, and there is another debt in the country itself, amounting to about 2,500,000 Spanish dollars, which was contracted during the Spanish dominion.

In the late civil wars sometimes 8000 men were under arms; it is now stated that the regular troops consist of 1800 men, and that there are upwards of 20,000 militia.

The coast of Honduras was discovered by Columbus in 1502. When the Spaniards had conquered Mexico, and formed settlements on the isthmus of Panama, they began to enter Central America from the N. and S. They effected the subjugation of these countries between 1524 and 1536, but they were never able to conquer the Indians who inhabited the country from Cape Camaron to the mouth of the Rio S. Juan. During the wars which took place in South America before 1820, Central America remained quiet, and subject to Spain. The proceedings of the Spanish Cortes in 1820 gave rise to the declaration of independence on September 16, 1821. For a short time the country was united to the Mexican empire of Iturbide; but on July 2nd, 1823, the new constitution was published, according to which the federal government of Central America consists of a president, who is chosen every four years and invested with the executive power, and of a congress, composed of a senate and a house of representatives. Every state sends two members to the senate, and one member to the house of representatives for every 30,000 inhabitants. This constitution, though perhaps applicable to nations in other circumstances, seems not fit for Central America. Since its formation it has been the theatre of nearly continual civil wars, in which much blood has been shed. (Haefkins's *Central Amerika*; Thompson's *Official Visit to Guatemala*; Dunn's *Travels to Guatemala*; Humboldt; Ivarros's *History of Guatemala*; *Communications from Col. Galindo*.)

CENTRARCHIUS, a genus of fishes of the section Acanthopterygii, family Percoides, and belonging to the subdivision 'with less than seven branchial rays.' In this genus the species have numerous spines in the anal fin: the tongue is furnished with a group of fine and very thickly set teeth; the pre-operculum is entire; the angle of the operculum is divided into two flat points; and the body is compressed and somewhat oval: they inhabit the rivers of North America. The genus *Cyelia* of some American ichthyologists is synonymous with the above.

CENTRE, CENTER, from the Greek *κέντρον* (*kentron*), a sharp point. This word, by its successive introduction in one sense and another, has become a generic term for any point of a figure or solid body, such that the whole of the figure or body might be collected into that point, without any alteration in some respect or other which is specified. It is, in fact, an average point, as the following detail will show.

1. *Centre of Figure*.—If any number of points be situated in given positions with respect to a plane (A), their average perpendicular distance from the plane is common to all the points of a second plane (B), parallel to (A). If two other planes (A') and (A'') be taken, and if (B') and (B'') be planes distant from them by the average distances of the points, then (B), (B'), and (B'') will meet in a point which is obviously distant from the three planes by the several average distances of the points. And it is proved, by the application of algebra, that the point thus determined is also distant from any other plane whatsoever by the average distance of the points; whence it may be called the *centre of figure* of the points. It is usual to call it the *centre of gravity*, which it is on one particular supposition only, namely, that the points are supposed to have equal weights.

A solid figure cannot be supposed to be made up of points; but if it be divided into a number of equal elementary portions, and if one point be taken in each, and the centre of figure then found in the manner just described, the principles and processes of the integral calculus will determine the centre of figure of the portion of space within the limits of the solid. Thus, as before, is only the centre of gravity, on the supposition that the solid is of uniform density throughout.

The centre of figure may be made useful in finding the content of surfaces and solids formed by revolution, as follows:—

1. If an area revolve round an axis the surface traced out is equal to a rectangle, one side of which is equal in length to the arc, and the other to the area of a circle through which the centre of figure of the revolving area passes.

2. If an area revolve round an axis, the volume of the solid thus generated is equal to a cylinder or prism, which has the area for its base, and the arc traced out by the centre of figure of the area for its altitude.

These propositions are the foundation of what has been called the *centro-baryc* method. [GULDING.]

3. *Centre of Gravity*.—This is the point at which the weight of the body being collected, the equilibrium of the body and of the system, if any, of which it forms a part, will not be disturbed.

4. *Centre of Gyration*.—This term, almost peculiar to English mathematicians, and is now has the following meaning: it is the point at which, if the whole of the matter in a body were collected, given forces would produce the same angular velocity of rotation in a given time as they would do if the particles of the body were distributed in their proper places. This centre is of course dependent upon the axis of rotation as well as the form, &c. of the body; every axis which can be chosen has its own centre of gyration.

5. *Centre of Percussion*.—That point of a revolving body which would strike an obstacle with the same force as if the whole of the matter were collected in it.

6. *Centre of Oscillation*.—The point in which the whole of the matter must be collected, in order that the time of oscillation may be the same as when it is distributed.

7. *Centre of Pressure*.—The point at which this whole amount of pressure may be applied with the same effect as it has when distributed. For methods of finding these several centres, see GRAVITY, &c., CENTRES OF.

In old writers, from the earliest periods, the term *centre* is used in the sense of a supposed centre of the universe, which it was imagined must coincide with the geometrical centre of the earth. And it was supposed to be a most obvious principle that all bodies must fall to this centre; which being a notion derived from the observation that all bodies fall towards the centre of the earth, was made an argument in favour of the stability of the latter. Even Copernicus has a notion of the existence of such a centre, or *medium mundi*, which, however, he places in the sun. It is hardly necessary now to say that there is no evidence whatever for the existence of any centre of the universe, that is, of any point which must necessarily remain fixed; but so well fixed was this notion in former times, that even if the earth were to be annihilated, it was supposed this centre would still exist with all its properties.

CENTRIPETAL and **CENTRIFUGAL FORCES**, forces which urge a body to *seek* (petere) or to *avoid* (fugere) a centre; in more modern language, attractive and repulsive forces. [ATTRACTION, REPULSION, FORCE, GRAVITATION, &c.]

We intend here to confine ourselves to the term *centrifugal force*, in one particular sense in which it is used in mechanics and astronomy, because it involves a point which is frequently mistaken. The term *force*, as used in mechanics, implies simply any cause of motion which is external to the matter moved; and the terms *accelerating force*, as well as *retarding force*, are used with reference to the velocities of bodies, and without reference to their masses or weights. So long as velocity remains unaltered, there is neither accelerating nor retarding force: when alteration of velocity begins, then we may say that force begins to act, for all we know of force is implied in the words 'cause of acceleration or retardation.' Again, owing to the convenience of words implying causation, it is usual to give the name *inertia* to that property of matter by which it maintains its state, either of rest or motion, unless acted on by other matter. And since the state of matter left to itself is either that of rest or of uniform motion in a straight line, every other species of motion, of what sort soever, is an effect of force from without; which assertion is verified in every instance in which it can be tried.

Suppose we fasten a string to an immovable obstacle, such as a post, and pull it, say with a force of a hundred weight. It may not at first sight appear proper to say that the post also pulls the string, because we may not be able to conceive the latter acting, but only resisting. Nevertheless, the part which the post sustains, calls its action or resistance, is still the equivalent of a force; for if it were

removed, and another hand applied to the other end of the string, that hand must also press against the first with a force of a hundred-weight before the counteraction of the moving tendency of the first pressure is supplied. And in taking the numerical effects of pressures, the equations of action can take no cognizance of the cause of the pressure, but only of their amounts; whence it will arise that the effect, say of the resistance of an immovable obstacle, may enter an equation in precisely the same manner as a physical attraction [Attraction], a muscular effort, or any other mode of accelerating or retarding velocity.

Now, it must be remembered that no alteration whatever of the effect of inertia can be produced without force of some kind. Let us now suppose a small bullet attached to a string, which string is fastened to a point upon a table, friction and the resistance of the air not being supposed to exist. Let the bullet be placed in a state of revolution round the fixed point, by means of the string, and with a given velocity. It will continue to revolve round with the same velocity, and the string will be stretched by a pressure depending upon the mass of the bullet and its velocity. The reason of the permanence of the velocity is contained in a proposition which is demonstrated in mechanics, namely, that forces applied to a material point in the direction perpendicular to that of its motion cannot change its velocity, but only its direction. If, for instance, a hand could apply pressure to a moving point on a table, by means of a string, so adroitly as always to keep the pressure perpendicular to the direction of motion for the time, the whole amount of the pressure might be varied so as to make the point describe any curve, but always with the same velocity as at the outset. Now, in the present case, the bullet must describe a circle, and the direction of the string, in which the retaining pressure acts, is always perpendicular to the tangent of the circle, being always a radius. This pressure of the string must be caused by an effort to escape on the part of the bullet, arising from its tendency to continue its motion in the direction of the tangent. This is the centrifugal force; and does not arise from any tendency which the body has to fly from the centre, but from this circumstance, that there is in the motion above described a constrained approach to the centre, or rather a constrained continuance at the same distance from the centre, such as would not exist in the motion of the bullet uninfluenced from without.

This centrifugal force is thus measured: suppose, for instance, the velocity of revolution in the circle to be 8 feet per second, and the radius 10 feet. Divide the square of the velocity by the radius, or divide 64 by 10, which gives 6.4. Then the pressure is such, that were it to take the place of the earth's attraction, the bullet, being allowed to fall, would, at the end of one second, have acquired a velocity of 6.4 feet per second, instead of 32, which is the case with bodies falling freely to the earth. And if we ask what weight must be hung to the string, so that it may receive the same pressure as when constraining a bullet of 2 pounds in weight to move at 8 feet per second in a circle of 10 feet radius, the answer is, such a proportion of the weight of the bullet as 6.4 is of 32,

$$\text{or } \frac{6.4}{32} \times 2 \text{ pounds, or on } \frac{384}{965} \text{ of a pound.}$$

If then this latter weight, hung at its end, would be the utmost the string would bear without breaking, then any accession of velocity in the preceding motion would also break the string.

We now take the case of one of the planets moving in the curve A P about the sun at S, and attracted towards the sun, so that if reduced to rest for a moment at P, it would immediately begin to descend towards S. It must always appear to one not used to consider these subjects, that this attraction being perpetually exerted must at last make the planet fall into the sun. But suppose for a moment the attraction removed, so that the planet would pursue its course along P T. Prevent this by an inextensible string S P, in which case the planet will proceed in the circle P V, not with the whole velocity with which (but for the string) it would have proceeded along P T, but with a part, as follows:—Let P T be the length which would be described in a second, draw P Y perpendicular to S P, and complete the rectangle P T Y. Then the velocity P T might be produced, if the string were not there, by an instantaneous communication of the two velocities P X and P Y in these directions. But when the string is supposed, the continu-

nuation of such an impulse as would produce P X has no effect except an instantaneous tension of the string, which is supposed capable of resisting it. There remains only P Y, which would produce what has been before called the centrifugal force.

Now, if the string were not there, there remains the body P, with the same tendency to recede from the centre implied in its having the velocity P Y, and with the effect, which would be counteracted by the string, entirely uncounteracted. If then we look at the paracentric motion only, or the manner in which S P is lengthened or shortened, independently of the angular motion, we have, 1. the paracentric velocity P X actually existing; 2. the attraction of S in the direction P S; 3. the tendency to recede from the centre arising from the velocity P Y. The alteration of the first is not due to the second or third alone; if (2) exceeds (3) the velocity P X is diminished in the instant next, following the body being at P; if (3) exceed (2) it is increased.

To realize the supposition above alluded to, namely, that the attractive force must bring the body P to the centre at last, we must put that force in a situation to act unopposed. Imagine a string which shortens as the body approaches the centre, so as always to remain stretched; and also suppose the attractive force to act, the effort to proceed in the tangent of the circle being destroyed by the string, and we have the case which is really supposed in the above mistake, for want of considering the centrifugal force.

The centrifugal force always (whatever the attraction may be) varies as the inverse cube of the distance, while the attractive force varies as the inverse square. Consequently if the revolution ever bring the body to 1-10th its primitive distance, the attraction is only 100 times as great as at first, while the effort to recede is 1000 times as great. Hence a very little knowledge of algebra will make it apparent that however much the external attraction may at first exceed the centrifugal force, there must come a point of approach to the centre at which the latter begins to exceed the former. And hence the alternate approach and recession of the planets to and from the sun. Let A Z M P N V be the

ellipse of a comet's orbit (we have drawn it too elongated for that of a planet). A and P the aphelion and perihelion, A P the axis, and M N a perpendicular to it. Let the planet be projected at A with the necessary velocity: then from A to M the attraction exceeds the centrifugal force, and velocity towards the centre is created, as instanced by Z Q in the figure at Z. At M the attractive and centrifugal forces are equal; and from M to N the centrifugal exceeds the attractive, so that between M and P the velocity towards the centre is destroyed; and from P to N velocity from the centre is created. After N the attraction is again in excess, and between that and A the velocity from the centre is destroyed; after which the succession recommences.

Some readers may perhaps not find it easy to conceive how the centrifugal should exist, when the pressure of the string, which it appears to counterpoise is not present. On which we must observe that the string does not make this effort to recede, but destroys its effect. If it is clear that there must be a pressure on the string in the first illustration, it is because, under the circumstances, there is a force to cause that pressure already existing. There are numerous experiments in illustration of centrifugal force; take a tube, for example, and place a bullet inside it; let the tube be then put into a state of rotation round one end, and the bullet will be projected straight from it. The governor of a mill or steam-engine is an instance in which this effort to recede is made useful. But the largest scale on which the centrifugal force becomes visible is in the alteration of the time of oscillation of a pendulum in going from one part of the earth to another. Let *A* be the point of suspension

of a pendulum *P*, and *PM* the line drawn through it perpendicular to the earth's axis, so that the angle *APM* is the latitude of the place. The motion of the earth carries the pendulum round in a circle of which *PM* is the continuation of the radius, so that there should be a slight action on the pendulum, such as should result from a pressure in the direction *PM*. Resolve this into *PQ* and *PZ*; the second will alter the position of equilibrium of the pendulum, the first will counteract a small part of the weight. The second will never be made visible; nor the first, except in comparing the number of oscillations of the same pendulum in different places. For the weight of the pendulum being differently lessened in different places, but the mass always remaining the same, the accelerating force is altered. For the law of the alteration, and the history of its discovery, see PENDULUM.

Among the various speculators on the cause of attraction we find those who have supposed both the phenomena of attraction and of centrifugal force to arise from causes external to the matter acted upon; and some have attempted to explain the former by an influx of particles to the sun, and the latter by an efflux from it. Thus one says, 'The acting power in the centrifugal force is the solar rays.' But what becomes of that effort which would cause the string to be stretched when a stone is whirled round at the end of a string, these speculators do not tell us.

CENTRISCUS (Linnaeus), a genus of fishes of the section Acanthopterygii, and family Fistulariidae. The species of this genus are principally distinguished by their having a long tubular snout, from which character they have received the names of sea-snipes, trumpet-fish, &c. The body is inclining to an oblong oval form, compressed, carinated beneath, and covered with scales. The mouth is small, obliquely cleft, and devoid of teeth. There are two dorsal fins; the rays of the first (which is placed very far back) are spinous; the ventral fins are small, and situated behind the pectorals.

Centiscus scolopax (Linnaeus), the trumpet-fish or sea-snipe (known in Cornwall by the name of the bellows-fish), is the only species yet discovered off the British coast, where it is rare; the Mediterranean appears to be its natural locality. Its length is about five inches; the body is oval and compressed; the snout is elongated, and forms a tube which extends about an inch and a half before the eyes, which are large; the back is elevated, and the part for some little distance anterior to the first dorsal fin is straight, from whence it tapers rather suddenly to the tail. The anterior spine of the first dorsal (which has but three rays) is very large and denticulated beneath; the rays of the second dorsal are soft; the anal fin is elongated; the ventrals are small, and have a depression behind them, in which they may be lodged. The body is covered with hard rough scales, which are minutely ciliated on the external edge.

Young specimens of this fish are of a shining silver-like colour; the adult specimens are reddish, with the sides of the head and under parts silvery or slightly tinted with a golden hue.

There is a figure of this curious fish given in Yarrell's 'British Fishes,' and also in Donovan's 'British Fishes.'

The genus *Amphisile* of Klein is closely allied to, and was included in, the genus *Centriscus* by Linnaeus; the species have the back mailed with larger scaly plates, of which the anterior spine of the first dorsal fin appears to be a continuation.

CENTROLOPHUS, a genus of fishes of the section Acanthopterygii, and family Scombridae. Technical characters:—body elongate, covered with minute scales; teeth small and numerous; palatine without teeth; one very long dorsal fin.

Centrolophus morio, called the *Black Fish*, has been met with, though very rarely, on the British coast. It is of a black colour, the fins intensely so; the under parts are of a slightly paler hue. The head is rather blunt and rounded in front, and the mouth is small; the eyes are prominent; the body is compressed, and, in a specimen fifteen inches long, is about three inches deep. There is a thin elevated ridge on the back, to which the dorsal fin is attached; this fin commences before the middle of the back (viewing it from the side), and extends almost to the tail; the pectoral fins are pointed; the ventral fins are bound down by a membrane; the tail is large and forked; the body is covered with very small scales.

In Mr. Yarrell's 'British Fishes,' one specimen is described as being fifteen inches long, and another 'measured two feet eight inches in length, and weighed fourteen pounds. The skin was observed to be so tough as to be stripped from the fish like that of an eel: no air-bladder was found. The taste was delicious.' They were caught off the coast of Cornwall, and the species is described as having great strength and velocity.

CENTRONOTUS (Lacep.), a genus of fishes of the section Acanthopterygii, and family Scombridae. In this genus the spines, which in most of the Acanthopterygians form the anterior dorsal fin, are free or unconnected by membrane; they have all ventral fins.

The above characters are common to a large number of species of the Scombridae, and hence it has been thought convenient to seize some minor distinctions for the purpose of dividing the genus *Centronotus* into several subgenera. In Cuvier's 'Règne Animal,' they are as follows: subgenus *Naucrutes*, or those in which the body is elongate; the tail carinated at the sides, and which have two free spines before the anal fin. To this subgenus belongs the Pilot Fish (*Naucrutes ductor*), which is well known for its habit of following vessels to a considerable distance in order to feed upon what is thrown overboard; and it is under such circumstances that this fish has been occasionally met with on the British coast. It is about a foot in length, and of a bluish grey colour, with five broad bands of deep violet. Its shape is something like that of the mackerel, but less tapering towards the head and tail. The pectoral and ventral fins are of moderate size, the latter very close together; the dorsal fin commences about midway between the head and the tail, and continues almost to the latter part; anterior to the dorsal fin there are three free spines: the tail is forked.

Subgen. *Elacates*. The species of this genus have nearly the form of the one last mentioned, but differ in the head being depressed, the tail not carinated, and there being no free spines before the anal fin. The next subgenus, *Labiola*, has free spines before the dorsal and anal fins, and the tail not carinated at the sides. In front of the dorsal spine there is a single one laid flat and pointing forwards. The Scomber amia of Linnaeus, a large fish upwards of four feet in length, which inhabits the Mediterranean, belongs to this section. There are two other species known, from the same locality; the one here mentioned is distinguished by the lateral line being much curved and turning an S. The last subgenus, *Trachinotus*, differs chiefly from *Labiola* in having the profile of the body deeper, and the dorsal and anal fins longer and more tapered.

CENTROPOMUS, a genus of fishes belonging to the section Acanthopterygii, division Thoracic-perches, and family Percoides. In this genus the muzzle is compressed, as in the eel, and the head, when viewed from the side, is much pointed; the lower jaw projects beyond the upper; the

pre-operculum and operculum are covered with scales; the former is dentated, and the latter serrated. There are two dorsal fins, with a distinct intervening space; the anterior one has eight and the posterior eleven rays; the teeth are very minute and crowded; the ventral fins are under the pectorals.

C. sea-pike, so named from its having eleven rays to its posterior dorsal fin, is common throughout South America, where it forms a considerable article of consumption, and is known by the name of the 'sea-pike'; it frequents the mouths of great rivers, and sometimes extends its course up as far as the fresh water.

The sea-pike grows to a considerable size, and weighs sometimes as much as twenty-five pounds; the body is of rather a more elongated form than the common perch; its colour is greenish-brown above and silvery beneath; the anterior dorsal fin is grey; the other fins are yellowish, and finely dotted with black on the edges; the lateral line is black. This species is the only one of the genus known, and is the *Sciaenidae undecimalis* of Bloch.

CENTROPAGES (Cuvier), a genus of fishes of the section *Actinopterygii*, and family *Percoides*, and belonging to the division with seven branchial rays, and a single dorsal fin. This genus is distinguished chiefly by the species having all the teeth fine, rather strong and recurved, and closely set: the pre-operculum is serrated; and the operculum is spined.

Centropages nigricans, one of the species known by the name of the black-perch or black-bass, is abundant in the rivers of the United States, and is much esteemed for the table. It is of a deep olive-green colour above, and fish on the under parts; the dorsal fin is bluish, with pale transverse bands; the other fins are of a deeper hue; the tail and anal fins are spotted.

This species is remarkable for having the tail doubly notched, the central and two outer parts projecting. This character, however, is not so distinct in old individuals. The young are marked with clouded transverse bands.

[*Centropages nigricans*.]

There are some few other species found on the American coast, the one above described is the *Perca varia* of Mitchell. (See the *Transactions of the Literary and Philosophical Society of New York*.)

CEOS. [ZEA.]

CEPHEALIS, a South American genus of Cinchonaceous plants, remarkable among other things for their flowers growing in close heads, and being surrounded by involucrating bracts, which are sometimes richly coloured. They are chiefly interesting from comprehending the plant which yields the ipecacuanha root of the druggists. This, the *Cephaelis Ipecacuanha*, is a native of the forests of Brazil, growing in close damp shaded places, and flowering in the months of January and February; it was also met with by Humboldt and Bonpland in the mountains of New Granada. It is a perennial plant, with a weak stem not above two or three feet long, and usually lying almost prostrate. Its roots are contorted, from four to six inches long, about as thick as a goose-quill, and separating into rings which are about half as thick as the whole diameter of the root. The leaves collect about the end of the stem or its branches, are of an oblong ovate figure, slightly hairy, from three to four inches long, and connected by deeply-lobed fringe-like stipules. The flower-heads are very small, surrounded by green bracts, and placed upon the end of a long pedicel; when in flower they are said to be erect, but they are represented as being pendulous in that state as well as when in fruit. The flowers are small and white, and are succeeded by little purple berries. The Puri and Coroado Indians chiefly collect this drug, which furnishes them with a valuable means of barter with Europeans; they rather it at all seasons of the year, principally however in

January, February, and March; and the only care they take is to separate the roots from the stem, to lay them up in bundles, and to dry them in the sun.

CEPHALANTHUS OCCIDENTALIS, or button-wood, is a North American plant, belonging to the natural order *Cinchonaceae*, of which it is one of the most northern representatives. It derives its English name from the round balls of flowers with which it is covered in the month of August. This plant is common in swamps, ponds, and stagnant waters, from Carolina to Canada, forming a shrub from six to fifteen feet in height, with a light spongy wood. The inner bark of its root is an agreeable bitter, and is frequently used as a remedy in obstinate coughs, according to Elliot.

CEPHALOCULUS, Lamarck's name for a genus of Branchiopoda, which he established for the *Polyphemus Oculus* of Müller, and which he places next to *Cyclops*. [BRANCHIOPODA.]

CEPHALONIA, the ancient Cephallenia (*Κεφαλληνία*), an island near the west coast of Greece, and the largest of the seven Ionian islands which form a state under the protection of Great Britain. The greatest length of the island, N.N.W. and S.S.E., is 31 miles; from Cape Viscardo, 38° 29' N. lat., to Cape Scala, 38° 4'. Its breadth is very unequal, the island being indented by several gulfs, the principal of which, on the S.W. coast, called the Bay of Cephalonia, extends eight miles into the island, and forms a large harbour. The breadth of the island about the middle is about ten miles; but in the N. part it is nearly double. Cape Scala is twenty-three miles W.N.W. of Cape Chiarenza, the nearest point of the coast of Morea, and eight miles N. by E. of Cape Skinari, the northernmost point of Zante. Cape Viscardo is five miles S. of Cape Dukato, the southernmost point of Santa Maura. Cephalonia is 24 miles from the nearest points of the coast of Aetolia and Acarnania, near the mouth of the Aspro Potamos and towards the entrance of the Gulf of Patras. The small island of Ithaca stretches alongside of the northern half of the E. coast of Cephalonia, being separated from it by a narrow channel from two to three miles wide. The area of Cephalonia is about 348 square miles, and the population in 1833 was 55,447; of whom 12,195 were agriculturists, 1771 manufacturers, and 815 were employed in trade. There were about 8000 acres sown with corn, 6242 planted with currants, 432 with olive trees, 12,232 with vines, 1000 with cotton and flax, and 1000 with pulse, besides 1634 acres of pasture, and 184,786 of uncultivated land. (*Official Returns of 1833 in the Tables of the Revenue, Population, &c. of the United Kingdom and its Colonies: Supplement to Part IV.*)

A calcareous ridge runs across the island from N.W. to S.E., and its lower projections cover nearly all the island, and jut into the sea in many places. The highest summit, called Oros Ainos, is about 4000 feet high, on which was a temple of Jupiter. There are no remains of the temple, and the mountain is covered with a forest. From the summit there is a splendid view over Acarnania, Aetolia, and as far as the mountains of Loeris, embracing a great part of the gulf of Lepanto, and southwards to the mountains of Argadia. The only plain in the island lies between Argostoli and Livato, in length about six miles, and is chiefly planted with vines, which give a fine delicate wine, though not fit for exportation. The chief produce of the island is currants, of which considerable quantities are yearly exported. It also produces oil and cotton. The other productions of the soil are oranges, lemons, figs, carobs, and an excellent sort of melons. In 1833 there were on the island 14,023 horned cattle, 26,323 sheep, 14,273 goats, and 3776 horses. The sea abounds with fish, and the mountains with wild pigeons and other game. The climate is very mild, but subject to storms and violent rains. Cephalonia is also subject to earthquakes.

As in ancient times, the island is still divided into four cantons or districts, Argostoli, Lixuri, Livato, and Asso. Argostoli, the principal or capital town of the island, lies at the foot of a mountain on the W. shore of the bay of Cephalonia. It consists chiefly of one street and a market-place; the houses are low; it has a good harbour fit for ships of the largest size, a lazaretto, and about 5200 inhabitants. The immediate neighbourhood is marshy and unwholesome. The civil and criminal courts of the island sit at Argostoli. Opposite Argostoli, across the bay, is the town of Lixuri, which has a better appearance than the capital, is in a more wholesome situation, and has 5000 inhabitants. In the neighbourhood of Lixuri are some remains of the ancient Pale,

one of the four principal towns of old Cephalonia. The Catholic bishop resides at Lixuri. Lixuri, at the north end of the gulf, has considerable trade. Also, the ancient *Epivrosus*, is an old fortress built by the Venetians on a peninsula in the north part of the island. There are besides several large villages, such as Tinea, St. Eufemia, Nauridaki, Kallita, Zola, &c. The Cephalonians are said to be a spirited, intelligent, industrious, and persevering people, and to show the greatest aptitude for learning of all the natives of the Ionian islands. They have produced several distinguished men, and many of them have risen to rank in the Russian service, both military and naval. In most Turkish towns there are medical practitioners from Cephalonia. Under the Venetians there were frequent quarrels among rival families and factions in the island, with whom revenge was an hereditary feeling. Cephalonia has manufactures of cottons, and of carpets of mixed wool and goats' hair, called *Zenie*, which are exported chiefly to Italy. There are also potteries, and distilleries for liquors. Many of the Cephalonians are employed as sailors. Others depart in the summer to the Morea to assist in the harvest. *Chelidonia* is common among them, and are accustomed to eat salt-fish diet and the bad water they drink. In the island of *Samos*, there is a native militia for the defence of the island. Under the Venetians the population of Cephalonia was calculated at about 50,000 (*Topographie de l'Épave*, 1787). The greater part of the population are of the Greek church, and have their *papas* and *calovers*, or monks; the others are of the Latin church, and have a Roman Catholic bishop, and several convents of Franciscans. There are 11 free schools supported by the government, and attended by about 500 pupils, besides 78 private schools attended by 1200 boys.

In old times Cephalonia was known by various names. In the *Odyssey* calls it *Samos*. Its older inhabitants have been a colony of *Leleges*. Same was also one of its principal towns on the east coast of the island, in ruins in Strabo's time (p. 455, &c). Thucydides calls the island *Tranapolis*, from its four towns, Same, Pale, Cranii, and Proni. The Roman *Julius*, at the close of the *Ætolian* war, 189 B.C., the four districts or tribes of the *Cephalenians* to submit to Rome, which they did, with the exception of Same, a strong-built town, which sustained four months' siege against the Romans, but was at last taken and destroyed, and the inhabitants were sold as slaves. *Fulvius* triumphed over both the *Ætolians* and *Cephalenians*, (187 B.C. Livy, xxxix. 5.) Cephalonia remained subject to Rome until the division of the empire, after which it was subject to the Byzantine emperors till the twelfth century, when the Franks dismembered the eastern empire. Cephalonia was then subject to the family of *Tocco* from Naples, who were despots or princes of *Achaia*. One of these princes gave it to the Venetians in 1224. It was invaded by the Turks in 1479, and retaken by the Venetians twenty years after, who retained it till the fall of the Republic in 1797, when the French took possession of it, but being driven away by the Russians in 1799, Cephalonia was made part of the new state of the Seven Islands under the protection of Russia. By the peace of *Tilsit* in 1809, the French took possession of it again, but were soon after driven away by the English. For the present government of these islands see *Corfu*.

CEPHALOPODA (Zoology), *Malakia* (malakia) of Aristotle, *Mollia* of Pliny, *Cephalophora* of De Blainville, *Antibrachionophora* of Gray, a class of mollusks whose mantle, according to Cuvier, unites beneath the body, and thus forms a muscular sac which envelopes all the viscera. This body of ink is fleshy and soft, varying in form, being either sub-spherical, sub-plano-elliptical, or elongato-cylindrical, and the sides of the mantle are in many of the species extended into fleshy fins. The head protrudes from the muscular sac, and is distinct from the body: it is gifted with all the usual senses, and the eyes in particular, which are either pedunculated or sessile, are large and well developed. The mouth is anterior and terminal, armed with a pair of horny or calcareous mandibles, which bear a strong resemblance to the bill of a parrot, acting vertically one upon the other. Its situation is the bottom of a subconical cavity formed by the base of the numerous fleshy tentacular appendages which surround it, and which have been termed arms by some naturalists and feet by others. The appendages in the great majority of living species are provided with *aestabula*, suckers or cupping-glass-

like instruments, by means of which the animal adheres to the bottom of the sea, and to various objects attached to it, its power to forego these is a great feature, and is unpaired or armed with a pair of arms, or a pair of *onychophorae*. In the *Nautilus*, the power of adhesion is so perfect that it is not possible to separate the animal from its attachment.

Well observes in his *Brachionaria* that the muscular fibres continue continued, it is said, that the substance of the limb than to release it from its attachment: and even in the dead animal the suckers retain a considerable power of adhesion. The same author clearly describes the apparatus by means of which the *Nautilus* executes its functions. The circular portion of the disk is raised by a soft and tumid margin, and is of long slender folds of membrane, covering corresponding fasciculi of muscular fibres, converge from the circumference towards the centre of the sucker, at a short distance from which they leave a circular aperture: this opens into a cavity which widens as it descends, and contains a cone of soft substance rising from the bottom of the cavity, like the piston of a syringe. When the sucker is applied to a surface, for the purpose of adhesion, the piston, having previously been raised, so as to fill the cavity, is retracted, and a vacuum produced which may be still further increased by the retraction of the plicated central portion of the disk. Here we have an excellent description of the apparatus for 'holding on,' but the explanation stops short of showing how the operation of 'letting go' is effected. We well remember in our youth going far out with an old fisherman of Dawlish to visit his floating nets which he had laid for the pilchards. As we looked down into the clear blue water we could see that the number of fish entangled was great; but to the great discomfiture of the fisherman, who was eloquent on the occasion, almost every other fish was locked in the embraces of a cuttle-fish plying his parrot-like mandibles to some purpose. The fisherman, who seemed to regard these unbidden guests as an incarnation of all evil, carried a capacious landing-net, but so quick was the sight of these cephalopods, so ready were they in letting go and agile in darting back or sideways clear of the net, that, though the greedy creatures held on to the last moment, the fisherman did not secure above three out of the crowds that had spoiled his haul. Upon mentioning this to Mr. Owen, he informed us that the muscular arrangement enabled the animal, when it was disposed to let go its hold, to push forward the piston and thus in a moment destroy the vacuum which its retraction had produced. The same author has stated that in the calamary, the base of the piston is inclosed by a horny hoop, the outer and anterior margin of which is developed into a series of sharp-pointed curved teeth. These can be firmly pressed into the flesh of a struggling prey by the contraction of the surrounding transverse fibres, and can be withdrawn by the action of the retractile fibres of the piston. [Truthful.]

Digestive Organs.—The tongue, which is beset with horny points, lies between the mandibles, and the oesophagus widens into a kind of crop which leads to a gizzard nearly as fleshy as that of birds. To the gizzard succeeds a third stomach, which is membranous, and somewhat spiral, wherein the liver, which is of considerable volume, pours the bile. The rectum opens into the infundibulum.

Respiratory Organs.—These are branchial, and the branchiae are equal, symmetrical, and protected by the mantle under which they are concealed. The *infundibulum*, or funnel (*entonnoir* of the French), is a fleshy pipe or passage in front of the neck through which the respiratory currents pass and the excrements are discharged. The young, as in other classes, respire more quickly than the adult. Dr. Coldstream saw an *eslone*, one inch and a half in length, breathe eighteen times in a minute, while another of the same species, four inches in length, breathed only ten times in a minute.

Circulating Organs.—The higher organized Cephalopods present the remarkable circumstance of having three separate and well-organized hearts: one for the circulation of the arterial blood through the body, the other two for the propulsion of the venous blood through each gill or respiratory organ. Only the first of these hearts, or the 'system' present in the Peaky *Nautilus*, which is, according to the type of the lower order of the class, is, but the venous system is characterized by the gland appended to the branchial division, the venous cavity venous system.

* In the *Cyclopaedia*, the *Nautilus* is described as having three hearts.

Sexual Organs.—Separate and developed in distinct individuals. It is not determined whether impregnation is effected before the ova are excluded, during their exclusion, or after their exclusion, as to the opinion that it is effected by copulation, and the examination of the organs produces as little doubt as to the opinion. Cuvier however says there is reason for believing that the fecundation is effected by insemination, as in the majority of fish. The ovary of the female is situated in the bottom of the sac. Two ducts receive the eggs from the ovary and carry them out across two large glands, which envelop them with a viscid substance and unite them together into bunches like grapes. The testis of the male is situated much the same as the ovary, and leads into a deferent canal which terminates in a gonopodium placed on the left side of the vent.

Brain and Senses.—The brain is included in a cartilaginous cavity in the head, and gives off, on each side, a nervous cord which forms in each orbit a large ganglion, whence proceed innumerable optic nervous filaments. The eye is composed of numerous membranes, and covered by the skin, which becomes transparent in front of the organ, and sometimes forms folds which perform the office of eyelids. Owen has observed that the cornea of *Rossia* is defended by a circular fold of integument, which can be completely closed by an orbicular sphincter in front of the eye, a structure which is probably required in this species in order to protect the cornea against the spicula of ice, with which its native seas abound, especially in the summer or thawing season. In the calumary (*Ioligo*), on the other hand, there is no tegumentary fold. The ear is nothing more than a small cavity hollowed out on each side near the brain, without semicircular canals or an external tube, and in this cavity is suspended a membranous sac containing a limpid fluid and a small compact stony substance or otolith, a sort of *ossiculum auditus*.

Ink-bags.—This celebrated excretion is of a deep black, and, in those species which possess it (for it is not common to the whole family), is produced by a gland appropriated to its secretion and reserved in a small bag till the exigencies of the animal call for its effusion to cloud the surrounding water in order that it may conceal itself. It has been long considered that the celebrated Indian ink, imported from China, is manufactured from this secretion, but Cuvier observes that M. Rémusat has found nothing in the Chinese authors confirmatory of this opinion. That it makes an excellent pigment even after having been buried for thousands of years in the earth is proved by Dr. Buckland's fossil ink, which he submitted to a celebrated painter, who immediately inquired from what colourman such good sepia might be procured.

The skin of the naked species is changeable, showing spots which brighten and fade with a rapidity superior to the cuticular changes of the chameleon. [CHAMELEONS.]

Food.—Principally fishes and crustaceans; but there is little doubt that few animal matters come amiss to these mollusks, for they are most voracious.

Geographical distribution.—Very wide. Hardly any sea is without some species of the family. Captain Ross discovered a new genus (*Rossia*, Owen), in the Arctic ocean. Fabricius describes two species which frequent the coasts of Greenland. (*Fauna Groenlandica*, p. 361.)

Utility.—The flesh, especially that of the arms, is eatable, and is considered very nutritious. Though neglected in the British islands, it is brought to table in other countries. The arms, cut into portions and prepared for cookery, are to be frequently seen in the Neapolitan market. The cuttle-bone is used for ensues and manufactured into 'pounce' of the shops. The prepared ink is capable of being made into a pigment. That the naked Cephalopods formed a favourite dish with the ancients, and were considered not unworthy of the most exquisite cookery, there is no doubt. (See, for instance, Athenæus, *Deipnosoph.* lib. i. vi., vol. i., p. 14; lib. vii. lxxvii. et cxxx., vol. iii., pp. 140 et 199; lib. xiv. xvii., vol. v., p. 25; Schweighæuser's edition.)

The natural division of the class is into those Cephalopods which are naked (*Cephalopoda nuda*), and those which are protected by an external shell (*Cephalopoda testacea*). Of the former, *Sepia officinalis*, the common cuttle-fish, may be taken as an example; and the following cut will give a general idea of the form of a naked Cephalopod, but this varies in the different genera. In *Sepia officinalis* the soft parts are supported by a bony cuttle-bone, the well-

known cuttle-bone of the shops, and all the naked Cephalopods (not including *Ocythoe*) now existing, it would appear that some rudiment at least of a bony, horny, or cartilaginous support is to be found. [SEPIADÆ.]

[*Sepia officinalis*.]

a, *Sepia officinalis*; the dotted line shows the place and shape of the dorsal piece or cuttle-bone; b, the lower side of an acetalabulum of *Ocythoe rubra*; c, of an acetalabulum of *Eledone*.

The *Nautilus Pompilius* affords an example of the testaceous Cephalopods, or those which are protected by a shell. [NAUTILIDÆ.] It may be expected that we should here say something of Argonauta; but with submission to the high authorities entertaining a different opinion, we do not think that the claims of the species of *Ocythoe* found in Argonaut shells, as fabricators of those shells, are sufficiently made out to warrant us in classing the cephalopods lodged therein as testaceous cephalopods. [BELLEROPHON; CAMMARIA; PAPER NAUTILUS; SEPIADÆ.]

FOSSIL CEPHALOPODA.

These are multitudinous, and, in the bygone ages of the world, appear to have been powerful instruments for keeping down the other tribes of ancient Testaceous Crustaceans, and even fishes; for many of them—certain Orthocerata, and Ammonites for example—afford evidence of gigantic dimensions. In the periods prior to the chalk formation, and at the time of its deposit, they were the agents employed for this purpose, and were succeeded in the tertiary period by the fossil Trachelipoda, which are either entirely absent or very scarce in the secondary and transition series, while the fossil Cephalopods occur but rarely in the tertiary beds. The extinct Ammonite [CORNU AMMONIS], Baculite, Belemnite, Hamite, Orthoceratite, Turritite, and Scaphite, will readily occur to the fossil zoologist as some of the ancient class, to say nothing of the hosts of small multilocular shells which D'Orbigny has so elaborately illustrated as cephalopodous under the denomination of *Foraminifera* (*Asiphonoides* de Haan), but whose cephalopodous structure the acuteness of De Blainville first doubted from the examination of one of the genus (*Miliola*), which he has declared to be without any relation to a cephalopod in its organization, and which the careful labours of M. Dujardin, in his examination of the genera *Miliola*, *Vorticula*, *Rotalia*, *Truncatulina*, *Cristellaria*, *Melonia*, &c., in a living state, have proved to be animals infinitely lower in the scale of creation, and without any trace of cephalopodous organization. 'From these observations,' says Owen, in the excellent article above alluded to, 'it necessarily follows that the *Foraminifera* of M. D'Orbigny cannot be arranged with the cephalopods, or even placed in the molluscosous series. M. Dujardin therefore proposes to consider them as a distinct class of *Invertebrata*, under the name of *Symplect-*

and until further and better evidence be adduced to the contrary, we shall regard these minute animals as having only, in the form and structure of their shells, a remote analogical relation to the cephalopods.

SYSTEMATIC ARRANGEMENT.

Linnaeus comprised all the Cephalopoda known to him under the genera *Nautilus*, *Argonauta*, and *Sepia*. Pult arranged them as *Mollusca brachiata*. Cuvier, who divides the mollusks into six classes, arranges them as the first class, under the name also of Cephalopoda, and commences by dividing the Linnæan genus *Sepia* into the *Poulpes* (Poulps) *Octopus* of Lamarck, *Polypus* of the ancients; these he further subdivides into those which have their suckers (*acetabula*) arranged alternately in two rows running the whole length of the limb or arm; and the *Eledons* (*Eledone* of Aristotle), which have only one range of suckers running the whole length of the arm. He then proceeds to the genus *Argonauta*, and evidently leans strongly to the opinion that the Cephalopod usually found in the Argonaut shells is not a parasite, but the constructor of the shell. The fossil genus *Belemnites* comes next in succession, the animal of which he considers to have been analogous to that of *Argonauta*. Then come the Calmars, Calamaries (*Loligo*, Lam.), and then the *Onychoteuthides* of Lichtenstein, *Onychia* of Lesueur. The *Sepioides* follow, to which succeed the *Sepiotheutes* of De Blainville (*Chondrosapia* of Lenkard), and then the *Seiches proprement dites* (*Sepia* of Lamarck), the cuttles. Cuvier then proceeds to the genus *Nautilus* of Linnaeus, which he subdivides into the *Spirules* (*Spirula* of Lamarck) and the *Nautili*, properly so called. Under these *Nautilidae* he arranges the fossil genera *Lituus* of Breyn, the *Hortoles* (*Hortulus*) of Montfort, and the *Orthoceratites*. The *Belemnites* [BELEMNITE] come next, and of these no less than eighty-eight species have been discovered. The *Ammonites* [CORNU AMMONIS] follow, and lastly come the multilocular shells, *Les Camérines* of Bruguières, *Nummulites* of Lamarck, the *Foraminifères* of D'Orbigny [SYMPLECTOMEREA]. These last, for the reasons above given, are no longer to be placed with the Cephalopods.

Lamarck and Leach both adopt the name Cephalopoda, given to the class by Cuvier, and the former makes it the fourth order of his *Mollusca*, separating it into the following divisions:—

1st Division. Testaceous, polythalamous Cephalopods (*Immergés*). Shell multilocular, subinternal.

2nd Division. Testaceous, monothalamous Cephalopods (*Navigateurs*). Shell unilocular, entirely external.

3rd Division. Cephalopods not testaceous (*Sépiatres*)

1. Polythalamous Cephalopods.

These Lamarck defines as having a multilocular shell, partially or completely internal, and set in the posterior part of the body: and he thus subdivides them:—

* Shell multilocular with simple septa.

The septa have simple borders, and are without notched and sinuous sutures on the internal wall of the shell.

1. Shell straight, or nearly straight; no spiral nucleus.

Orthoceraia.

Genera. *Belemnites*,
Orthoceras,
Nodularia,
Hippurites,
Conilites.

2. Shell partially spiral, but with the last whorl continued into a straight line.

Lituolea.

Genera. *Spirula*,
Spirulina,
Lituola.

3. Shell semi-discoid; spire eccentric.

Gristacea.

Genera. *Remulina*,
Cristellaria,
Orbiculina.

* De Blainville, in his elaborate 'Mémoire on the Belemnites,' has given a list of ninety-one authors, from Theophrastus downwards, who have treated of these fossils. Count Munster has published a valuable paper on the subject. Dr. Buckland, in concurrence with M. Agassiz, proposes the name of *Belemnites* for the Cephalopod which secreted the fossil ink-bags; but this denomination comes very near to the *Belemnites* of Voltz. [BULOTTEA.]

4. Shell globular, spheroidal, or oval, with enveloping spiral whorls or chambers united tunically (*loges réunies en tunique*.)

Spherulea.

Genera. *Miliola*,
Gyrogonia,
Melonia.

5. Shell discoid, with a central spire and chambers radiating from the centre to the circumference.

Radiolea.

Genera. *Rotalia*,
Lenticulina,
Placentalia.

6. Shell discoid, with a central spire and chambers which do not extend from the centre to the circumference.

Nautilacea.

Genera. *Discorbis*,
Siderolites,
Polystomella,
Vorticialis,
Nummulites,
Nautilus.

** Shell multilocular, with septa notched or jagged on the borders.

Ammonica.

Genera. *Ammonites*,
Orbulites,
Ammonoceras,
Turrillites,
Baculites.

2. Monothalamous Cephalopods.

Shell unilocular, entirely external and enveloping the animal.

Genus. *Argonauta*.

3. Sepiarian Cephalopods.

No true shell, either internal or external. A solid, free, cretaceous or horny body contained in the interior of the greater part of these animals.

Genera. *Octopus*.

Loligopsis,
Loligo,
Sepia.

Such is Lamarck's arrangement, which is objectionable in many respects, especially in the Polythalamous division. To say nothing of the smaller multilocular shells, which, as we have already seen, more recent discoveries have removed from the Cephalopods, several of the genera are erroneous. *Hippurites*, for instance, belongs to the bivalves, and approaches very closely to the *Chamaea* [*Bucconites* and *Submytilacea*], and *Gyrogonia* has been found by Lyell to be a seed-vessel of a chara. De Blainville (1825) observes that it had become a general admission, since the remark of M. Leman, that the *Gyrogonites* found in the fresh-water formations were nothing more than the seeds of *Chara*.

Leach thus arranges the class:—

Cephalopoda.

Order 1. *Octopoda*.

Feet eight. Body finless.

Genera. *Eledone*,
Polypus,
Ocythoe.

Order 2. *Decapoda*.

Feet ten: the fourth pair much longer than the others. Body finned.

Family 1. *Sepioides*.

Genera. *Sepioida*,
Cranchia.

Family 2. *Sepiides*.

Genera. *Sepia*,
Loligo.

De Blainville makes this class the first of his *Malacostraca*, and names the animals forming it *Cephalopoda*, which he divides into the following orders and families:—

Order 1. *Cryptodibronchiata*.

Family 1. *Octopoda*. Tentacular appendages eight in number, forming four pairs. Border of the suckers

muscular. Body more or less globular, without any natatory expansion of the mantle, and without any dorsal protecting body. (Genus, *Octopus*.)

a. Species whose tentacula are very long, united at their base by a membrane, and furnished with a double row of suckers on their entire length. Example, *Octopus vulgaris*.

b. Species whose tentacula, agreeing in most other points with those of section a, are furnished with only a single row of suckers. (Genus, *Eledone* of Leach.)

γ. Species whose tentacula generally are shorter than those of the two first sections, and free at the base, and whose upper pair is bordered towards its extremity by a membrane. (Genus, *Ocythoe* of Rafinesque, the animals generally found in the shells of *Argonauta*.)

Family 2. *Decacera*. Tentacular appendages ten in number, consisting of five pairs, four of which are disposed much in the same way as those of the preceding family, though they are shorter, while the fifth pair, which is out of the rank, and between the mouth and the root of the third and fourth external pairs, is much longer, pedunculated, and furnished with suckers upon their enlarged and terminal portion only, which suckers are armed with horny processes on their border. Form of the body variable, but always provided with some lateral natatory expansion, and with a solid piece in the back. (*Calmar*, *Loligo*, *Calamarios*.)

a. Species whose body is globular and depressed. The superior border of the sac not distinct. Natatory appendages or fins circular, small, and as it were pedunculated, distant, and lateral. Dorsal-piece extremely slender. (Genus, *Sepiola*, Leach.)

b. Species whose body is more elongated, sacciform, and with the dorsal border of the sac not distinct. Fins or natatory appendages circular, still smaller than those of section a, pedunculated, and nearly touching each other at their origin on the back. Dorsal-piece not known. (Genus *Cranchia*, Leach*.)

γ. Species whose body is more elongated and subcylindrical. Fins large, triangular, terminal, lateral, and forming a triangle whose base is in front. Dorsal-piece straight, and in form of a three-edged sword. Tentacular appendages rather long. Brachial appendages with very long peduncles, and armed with suckers, whose horny border is in the form of an elongated claw. (Genus *Onychoteuthis*, Lichtenstein.)

δ. Species whose body and fins are nearly of the same form with those of section γ, but whose dorsal-piece is flatter and generally wider before than it is behind, where it terminates in a small excavated point. Tentacular and brachial appendages generally shorter. Suckers furnished sometimes with teeth or hooks in a portion of their border, which is more or less considerable, but never with true claws. (Example, *Loligo agitta*.)

a. Species whose body, nearly of the same form as that of the last section, has its fins less terminal. They are triangular, but so disposed that the two when united form a rhomb. Border of the mantle free, very much prolonged into a point on the superior medial line, by the projection of the dorsal-piece, which is always narrower before and widened behind in the form of a feather. Tentacular and brachial appendages much the same as in section δ; but the suckers are less often furnished with hooks. (Genus *Pteroteuthis*, De Blainville.)

b. Species whose oval, depressed body is furnished with straight fins through the whole length of the body, as in the cuttle-fishes, but whose dorsal-piece is the same as in the feather-like calamaries, although broader. (Genus *Septeuthis*, De Blainville.)

De Blainville, who rejects the genera *Loligopsis*, Lam., and *Leachia*, Lesour, concludes this order with the genus *Sepia*.

Order 2. *Celigiacea*.

This order contains the Foraminifera of D'Orbigny, and De Blainville guards himself at the very commencement from the supposition that he assigns the same situation to them as D'Orbigny. He observes, that it always seemed to him that it was by a forced analogy that the organized bodies that form this order were placed among the true po-

* N.B. The dorsal-piece is altogether wanting in *Cranchia*.

lythalamous shells. The following are the families into which De Blainville divides them:

- Family 1. *Spherulacea* (Miliola, &c.)
- 2. *Planulacea* (Rehulina, &c.)
- 3. *Nannulacea* (Nannulites, &c.)

Order 3. *Polythalamacea*.

Body contained in a lesser or greater proportion in the first (or rather the last) chamber of a polythalamous shell, or entirely inclosing it. Shell either straight, or more or less rolled up upon the same plane or superficies, divided into a considerable number of chambers, of which the first (or rather the last) is the largest, by septa, or partitions pierced by one or more siphons. De Blainville observes that this order is in truth established upon the incomplete knowledge then possessed as to the organization of the animal of *Nautilus* and *Spirula*, but that analogy shows an evident approach to them on the part of the *Belemnites*, the *Orthoceras*, the *Ammonites*, and some corresponding genera. It is not so, he adds, with *Hamites* and *Scaphites*, for we scarce know what they are. Since the 'Malacologie' was published, Mr. Owen has given to the world his anatomy of the *Nautilus Pompilius*, and the result of his anatomical researches into the structure of the other Cephalopods. We must return however to the system of De Blainville, who arranges the fossil shells which constitute this order according to the degree of incurvation or rolling up of the spiral cone.

Family 1. *Orthocerata*.

a. With simple septa.

Genera. *Belemnites*.

Shell conical, or a little compressed, straight, or hardly curved; hollowed at the base only into a conical cavity, wherein are piled, one over the other, simple concave septa, or partitions, pierced by a marginal siphon. This constitutes what is termed the alveolus. De Blainville divides the genus into many subdivisions, several of which have been separated into genera by Denys Montfort. Among them we may notice *Callirohe*, applied by Péron and Lesueur to a genus of *Ciliograda* [*Callirohe*], and generally adopted by naturalists, to the exclusion of Montfort's application of the term. See 'Malacologie' (1825), p. 376; and De Blainville's 'Memoir on Belemnites' (1827); Sowerby, 'Min. Con.', vol. vi. p. 169, et seq.; and Dr. Buckland's 'Bridgewater Treatise,' p. 371. [*BELEMNITE*]. In De Blainville's arrangement the following genera succeed *Belemnites*:—

Conularia.

Conilites.

Orthoceras.

β. With sinuous septa.

Genus *Baculites*.

Family 2. *Lituacea*.

Shell polythalamous, or chambered, symmetrical, rolled up for a more or less portion of its extent, but always straight towards the terminal part, so that the opening is never modified by the penultimate whorl. Partitions or septa either simple or sinuous, and pierced by a siphon.

a. Septa simple.

Genera. *Ichthyosarcolithes*.

Lituola.

Spirula (including *Hortolus* of Denys de Montfort, and *Spirolina* of Lamarck).

β. Sinuous septa.

Genera. *Hamites*.

Ammonoceras.

Family 3. *Cristacea*.

Shell generally very much flattened; symmetrical, except perhaps at the summit, which is eccentric and spiriform. The last whorl nearly straight, much larger than the others, which are not numerous. Opening variable, but not modified. Septa or partitions always visible externally.

Genera. *Crepidulina* (a name too nearly approaching *Crepidula* [*Calyptraeidae*]; the genus contains three genera, established by Denys de Montfort.)

Linthuria.

Family 4. *Ammonacea*.

Animal entirely unknown. Shell with the walls ex-

treely delicate, partitioned, discoid, and most generally compressed, not carinated, with a spire rolled or coiled up completely from the summit to the base in a vertical direction, and from behind forwards, so that all the coils or whorls are visible. The last whorl much larger than all the others, but modifying the opening very little. One or more siphons.

Genera. Discorites.
Scaphites.
Ammonites.
Simplegas (embracing four genera established by De Montfort.)

Family 5. *Nautilacea*.

Animal incompletely known from that of Nautilus. (But see NAUTILIDÆ, and Mr. Owen's clear and elaborate details of the whole organization of *Nautilus Pompilius*.)

Shell more or less discoid, compressed, rolled or coiled up vertically and very symmetrically on the same plane. The last whorl much larger than the others, which it entirely hides. Opening large and oval. Septa united in the greatest number of cases, and pierced by one or two holes.

Genera. Orbulites (embracing two of De Montfort's genera).
Nautilus (embracing three of De Montfort's genera).
Polystomella (embracing six of De Montfort's genera).
Lenticulina (embracing eleven of De Montfort's genera).

Family 6. *Turbinacea*.

Animal unknown. Shell more or less turbinated, not symmetrical, rolled or coiled up in such a manner that one side forms a flattened base, and the other is more or less elevated. Opening not symmetrical, partitions simple and entire.

Genera. Cibicides.
Rotalites (embracing three of De Montfort's genera).

Family 7. *Turriculacea*.

Animal entirely unknown. Shell delicate, partitioned, leaving a cast composed of a great number of articulations, twisted or coiled into a tower-like spire, the whorls of which are clearly visible. Opening rounded, not modified. Siphon subcentral.

Genus Turritites.

Such is De Blainville's arrangement.

Owen, who has so ably illustrated the anatomy and physiology of the class, makes the respiratory system the foundation of his arrangement. The following is the classification of the Cephalopoda proposed by him.

Order 1. Tetrabranchiata.

Most closely allied to the Gasteropodous mollusks. *Branchiæ* or gills four in number. Syn. *Polythalamacea* of De Blainville; *Siphonifera* of D'Orbigny; minus the *Spirulidæ* and *Belemnitidæ*.

Family 1. *Nautilidæ* (Nautilites).

Animal organized as described by Owen in his 'Memoirs on the Pearly Nautilus,' 4to. 8 plates, 1832. [NAUTILIDÆ.]

Shell external; spiral, or straight; simple; the last chamber the largest, and containing the animal: siphon central or marginal, and internal.

Genera. Nautilus (Lamarck).
Clymenes (Munster).
Campulites (Deshayes).
Lituites (Breyn).
Orthoceratites (Breyn).

Family 2. *Ammonitidæ* (Ammonites*, Snake-stones, Cornua Ammonis).

* In the number of the London and Edinburgh Philosophical Magazine and Journal of Science for July, 1836, Dr. Ruppell has published some observations on the fossil Genera Pseudammonites and Ichthyosagones of the Solenhofen Limestone, wherein, after referring to his paper published in 1829, he observes that one of these fossils (Anchylus, Meyer) is not unfrequently found within an Ammonite-like shell, but which has only an apparent likeness to the true Ammonite, for it has no internal septa. In many of these Ammonite-like shells there are found, near to their opening, two calcareous plates resembling in appearance a bivalve shell. These must, in Dr. Ruppell's opinion, have belonged to the animal which inhabited the Ammonite-like shell, and may, he states, have served as a kind of operculum to it, or perhaps as an organ for mastication; and, having observed a considerable number of these fossils, all of which confirmed the constant proportion of the diameters of the bivalve and Ammonite-like shell when joined together, he remains confident that they belonged to one animal, forming quite a new type in the series of Mollusca, for which he has proposed the name of *Pseudammonites*.

Animal unknown, presumed to resemble the Nautilus. Shell external; spiral or straight; septa sinuous, and with lobated margins; the last chamber the largest, and lodging the animal: siphon central or marginal, and external. [Cornu Ammonis, Zoology.]

Genera. Baculites (Lamarck).
Hamites (Parkinson).
Scaphites (Parkinson).
Ammonites (Bruguière).
Turritites (Lamarck).

Order 2. Dibranchiata.

Approaching nearest to the Vertebrate animals.

chins or gills two in number. Syn. *Cryptobranchiata*, De Blainville; *Acetabulifera*, D'Orbigny; plus the *Spirulidæ* and *Belemnitidæ*.

Tribe Decapoda.

Family 1. *Spirulidæ*.

Animal corresponding in external form to the decapodous type; internal organization unknown; presumed to be dibranchiate.

Shell partly internal, cylindrical, multilocular, discoid; the whorls separated; septa transverso, concave next the outlet, and with regular intervals. Siphon marginal and internal, uninterrupted.

Genus Spirula (Lamarck).

Family 2. *Belemnitidæ* (Belemnites, Thunder-stones).

Animal unknown. But 'as it is certain that the animals of this family of extinct Cephalopods possessed the ink-bag, they must consequently have been enveloped by a muscular mantle; and we may therefore infer that they resembled the dibranchiates in their locomotive and respiratory organs, and consequently in the general plan of their organization. In the structure and position of their siphoniferous cannerated shell, they are intermediate to *Spirula* and *Sepia*, and as the animal of *Spirula* is proved to be a decapod, the probability is very strong that the animal of the Belemnite was of the same type.'

Shell internal, composed of an external calcareous sheath, formed by a succession of hollow cones, the exterior being the largest; of an internal horny sheath, also of a conical form, containing at its apex a chamber, the septa of which are concave externally, and perforated by a marginal and ventral siphon. [BELEMNITE.]

Genera. Belemnites (Lamarck).
Actinocomax (Miller).
Pseudobelus (De Blainville).

Family 3. *Sepiidae* (Cattle-fishes).

Animal, body oblong, depressed, with two narrow lateral fins extending its whole length.

Shell internal, lodged in a sac in the back part of the mantle, composed of an external calcareous apex or mucro (point), of a succession of calcareous laminae, with intervening spaces filled with air, and supported by columns, but not perforated by a siphon, and an internal horny layer, corresponding to the anterior horny sheath of the Belemnites.

Genus Sepia (Cuvier).

Family 4. *Teuthidæ* (Calamaries, *teuthos* (teuthos), the term applied by Aristotle to the ten-armed *Malakia* (Malakia), with an internal horny plate or *gladius*).

Animal, body sometimes oblong and depressed, generally elongated and cylindrical; with a pair of fins varying in their relative size and position, but generally broad, shorter than the body, and terminal.

Shell internal, rudimental, in the form of a thin, straight, elongated, horny lamina; encoysted in the substance of the dorsal aspect of the mantle.

Funnel with an internal valve, and articulated at its base to two ventro-lateral cartilaginous prominences of the mantle.

Genera. Sepioteuthis (De Blainville).
Loligo (Cuvier).
Onychoteuthis (Lichtenstein).
Rossia (Owen).
Sepioida (Leach).

β. Funnel unprovided with an internal valve, and adherent at the antero-lateral parts of its base to the mantle.

Genera. Loligopsis (Lamarck).
Cranchia (Leach).
Tribe Octopoda.

Dibranchiate Octopods, besides wanting the long fin, are also characterised by the absence of mantle fins, and consequently are limited to retrograde progression while swimming; their acetabula are sessile and unarmed; they have two oviducts, but without detached glands for secreting a nidamentum.

Family 1. Testacea.

Body oblong, rounded, mantle adhering posteriorly to the head; first or dorsal pairs of arms dilated, and membranous at the extremity. Funnel without a valve, but articulated at its base by two ball-and-socket joints to the inner side of the mantle. Branchial hearts, with fleshy appendages. No internal horny or testaceous rudiments; but an external monothalamous symmetrical shell, containing, but not attached to, the body of the animal; which also deposits its eggs in the cavity of the shell.

Genera. Argonauta (Linnæus). 'On the supposition that the shell is parasitically occupied by the Cephalopod, but formed by some other mollusk, some naturalists limit the above generic title to the shell*, and call the Cephalopod *Ocythoe*. We shall however continue to apply the term *Argonauta* to the Cephalopod in question, as the evidence, though strong, is not conclusive of its parasitic nature.' [PAPER NAUTILUS.]

Bellerophon (Montfort).

Family 2. Nuda.

Body generally rounded, mantle broadly continuous with the back of the head. Arms connected at the base by a broad web; first pair elongated, and gradually narrowing to a point. Funnel without an internal valve, or external joints; branchial hearts, without fleshy appendages; biliary ducts, without follicular appendages. Shell represented by two short rudimental styles, encysted in the dorso-lateral parts of the mantle.

Genera. Octopus (Leach).
Eledone (Leach).

The arrangement, definitions, and observations in the last-mentioned system are entirely Mr. Owen's, and they are founded upon an acute and accurate demonstration and observation of the organization of the class. And though we may, with all facility, differ from him in a few points, we consider the system, taken as a whole, by far the most satisfactory that has as yet been proposed.

Those who would study the natural history, anatomy, and physiology of the class, should consult the works of Aristotle, Pliny, Swammerdam, Needham, Baker, John Hunter, Mourou, Scarpa, Tilesius, Cuvier, De Blainville, Home, Leach, Rathke, Bosc, Ruget, Grant, Poli, Delle Chiaje, Rafinesque, Carus, San Giovanni, Coldstream, Mayer, Lesueur, Ranzani, Broderip, Quoy and Gaimard, Gray, DeFrance, Montfort, Buckland, G. B. Sowerby, J. Sowerby, D'Orbigny, Férussac, Dujardin, Owen, and, above all, the article 'Cephalopoda,' by the last-named author, in 'The Cyclopædia of Anatomy and Physiology,' where the latest and best information as to the organization of the class is to be found.

CEPHALOPTERUS. [CORACINA.]

CEPHALOTES. [CHIROPTERA.]

CEPHEA. (Zoology.) [MEDUSA.]

CEPHEUS, a constellation, surrounded, by Cassiopeia,

Ursa Minor, Draco, and Cygnus, comes on the meridian at midnight in the middle of August, and at eight o'clock in the middle of October. A line drawn from the bright star in Cygnus to the Pole Star will be nearly bisected by a and γ of this constellation. Cepheus, King of Ethiopia, was the husband of Cassiopeia and the father of Andromeda, and was placed in the heavens, according to Hyginus, that no one of this remarkable family might be absent. He is represented in old plates as a man with a tiara on his head, kneeling on one knee, and with his arms extended.

CEPHISUS. [AFRICA, and ÆGOTIA.]

CEPHUS. (Ornithology.) [DIVERS.]

CEPHUS, a genus of Hymenopterous insects, of the family Xiphiidæ (Leach). The characters are—antennæ rather long, growing gradually thicker towards the apex; head transverse, joined to the thorax by a distinct and rather long neck; mandibles exerted; maxillary palpi long and slender; body somewhat compressed, especially towards the apex; ovipositor distinct, exerted.

Cephus pygmaeus is common in flowers, particularly buttercups; it is about one-third of an inch in length; black, with two yellow fasciæ on the abdomen; the palpi and tibiae also more or less yellow. The larva of this insect is said to live in the stems of wheat. Mr. Stephen enumerates ten British species of this genus, most of which are black, with yellow fasciæ.

CEPOLA (Linnæus), a genus of fishes of the section Acanthopterygii and family Tænioidei. The technical characters of this genus are:—Body much elongated, compressed and tapering gradually towards the tail, which is pointed; head (when viewed from the side) about the same width as the body; snout short and obtuse; under jaw curved upwards; teeth curved and well developed; dorsal fin extending from the head to the tail (which is pointed); anal fin extending from thence nearly the whole length of the body; branchiostegous membrane with six rays.

A species of this genus, which is found on the British coast, and likewise in the Mediterranean, is known in England by the names of the red band-fish and red snake-fish (*Cepola rubescens*). It is of a pale carmine colour, and varies from ten to fifteen inches in length; it is very smooth and almost destitute of scales; the body is slender, much compressed, and tapers very gradually from the head to the tail. The riband-like and compressed form of the body increases with age; the young are somewhat oval, or almost round. The pectoral fins are small; the ventrals are situated rather anterior to the line of the origin of the pectorals, and have the first ray spinous. The dorsal and anal fins both extend to and join the tail, or caudal fin (which terminates in a point), so that they form one continued fin. (Yarrell's *British Fishes*; Jenyn's *Manual of British Vertebrate Animals*; Linnæan Transactions, vol. vii., &c., where this fish was recorded as British for the first time by Col. Montagu.)

Cepola tænia (Linnæus) is said to differ from the species just described, in having a row of hard points along the side of the body, above the lateral line, and in having an inner row of teeth in the lower jaw; it is however very probably not a distinct species.

CERAM, an island in the Indian seas, between 3° and 4° S. lat., and 128° and 131° E. long., is, with the exception of Gilolo, the largest of the Molucca islands. Its length in a direction nearly E. and W. is 185 miles, and its average breadth about 30 miles; its area may be about 5550 square miles, but our maps do not enable us to ascertain it with any great accuracy. These dimensions include the peninsula of Hoewamochii, or Little Ceram, which is united to the main land at its western extremity by a narrow isthmus, called the Pass of Tamocno. A chain of very high mountains runs through the island from E. to W.; the highest summit is about 7000 feet above the sea. A cluster of small islands off the east end of Ceram are called the Ceram Laut islands. The soil in the valleys of Ceram appears to be fertile. The peninsula of Hoewamochii formerly produced great quantities of cloves and nutmegs, but the trees were destroyed by the Dutch about 1657. The wood known in commerce as Ambony wood is for the most part the produce of Ceram, which contains several large natural forests of the sago palm. The inhabitants of Ceram have been described by Dutch writers as people who have 'an unjust and cruel lust of blood and warfare, so that it would have been better if, instead of extirpating their trees alone, we had, says Valentyn, 'at the same time extirpated this revengeful and sanguinary nation.'

* We are of those who would continue such limitation.

It is probable that the disposition attributed to the natives of Ceram may have been called forth by the oppressions of the European settlers, and particularly by their destruction of the clove trees, which deprived the cultivators of the fruits of their industry and a profitable employment.

Ceram forms part of the government of Amboyna, and has followed the fate of that island as regards its different European possessors. [AMBOYNA.] The governor of Amboyna is accustomed to pay an annual visit to different parts of the coast of Ceram, accompanied by a numerous fleet of armed boats, containing native rajahs and other chiefs. The object of this voyage is, 'to examine into and decide upon all disputes that may arise among the Indians that are subject to the authority of the Europeans; to discover and prevent illicit trade, and to destroy such spice-trees as are found growing in places where they are not allowed.' (Stavorinus's *Voyages*; Hamilton's *East India Gazetteer*.)

CERAMMIUS, a genus of Hymenopterous insects of the section Diptera, Latreille. This genus is arranged by Latreille next to the true wasps; it is readily distinguished by the superior wings being flat (not folded as in the wasps) and having only two cubital cells; the labial palpi are longer than the maxillæ. [VESPIDÆ.]

CERAMBYCIDÆ, a family of Coleopterous insects of the section Longicornis, (Latreille). Distinguishing characters:—Body generally elongate; antennæ very long, as long or longer than the body; labrum very distinct and broader than long; maxillæ with the terminal processes membranaceous and projecting; mandibles moderate; eyes lunate, partly surmounting the basal joint of the antennæ; thorax nearly cylindrical, or orbicular, truncated before and behind; legs rather long, and generally compressed; tarsi spongy beneath, penultimate joint bilobed.

The Cerambycidæ are found in all parts of the globe, but they abound most in hot climates, and constitute a very extensive group of coleopterous insects, the most striking feature of which is the great length of the antennæ. One of their most important functions appears to be to assist with numerous other wood-feeding insects, in the removal of old and decaying trees: it is in the larva state principally that this business is performed. The parent insect deposits her eggs in a hole excavated for the purpose: when these are hatched the larvæ commence feeding upon the wood, and in so doing excavate burrows in various directions, but mostly longitudinal; in this state they frequently live for two or three years*, and the perforations which they make are very extensive.

The larvæ are elongate, broadest towards the head, and taper slightly towards the tail, and are composed of thirteen segments. They have six legs (situate one on each side, on the under part of the three anterior segments of the abdomen) which are so minute as to be scarcely apparent. They move chiefly by means of the segments of the body, which leave the upper and under surfaces flat and covered with minute tubercles. In making their way in the cylindrical, or, what is almost always the case, oval burrows, the animal protrudes those parts of the segments, above and beneath, and thus thrusts itself forward. The head has the appearance of being composed of two segments; the hinder part very broad (almost equalling that of the segment in which it is inserted), terminated on each side anteriorly by an angle and separated from the forehead, which is narrow, by an elevated ridge: the jaws (*mandibles*) are short and very stout and strong; the antennæ are scarcely visible, the palpi are small. The first segment of the abdomen, or that next the head, is protected by a shield above, of a horn-like substance.

The pupæ are what is termed *incomplete*, i. e. when the external organs (such as the wing-cases, antennæ, legs, &c.) are each enclosed in a separate and distinct sheath, and consequently not closely applied to the body, but have their form for the most part clearly distinguishable. The antennæ, which have been before described as being very long in the perfect insect, are bent backwards and lie along the back of the pupa until they reach the apex of the body; they are then recurved and extend along the under side, and, if very long, they are again recurved, so that they, as well as all the other parts, lie close to the body†.

The Cerambycidæ, in the perfect state frequent especially of the Umbelliferous kind; the large species often found on the trunks of trees. Different individuals of the same species vary extremely in size, a circumstance frequently observed in those insects whose larvæ feed on food, arising most probably from the degree of moisture or less of the food.

[Latreille restricts the genus *Cerambyx* to those species which have an unequal or rough thorax, usually spinous or tuberculated and dilated in the middle at the sides, with the third, fourth, and fifth joints of the antennæ evidently thicker than the following ones, and the remaining joints abruptly longer and thinner.

Cerambyx heros affords an example of the genus: it is about an inch and a half in length; of an elongate form, attenuated posteriorly; black; elytra with the apex pitchy, or brown; the thorax is rough and shining, and has a spine on each side. This species, together with another belonging to the same genus (*C. cerdo*), has been found in England, but it is extremely rare; in the warm and temperate parts of Europe it is common. The larva perforates the oak, and according to Latreille is perhaps the cossus of the antients.

The genus *Cerambyx* of Mr. Stephens and most of the British entomologists is synonymous with that of *Callichroma* of Latreille, whereas the characters given by him for *Cerambyx* agree with those of *Hamaticherus* of English authors.

The *Musk-beetle*, which is very common in the south of England on old pollard willows, will serve to illustrate the genus *Cerambyx* of Stephens's *Illustrations of British Entomology*; it is about an inch and a half in length, of an elongate and somewhat linear form; its colour is usually bright green, sometimes blue; the under part of the body is bluish.

This insect emits a very strong and agreeable odour, which is not unlike attar of roses. It certainly bears no resemblance to musk, though those who gave it the name of *Musk-beetle* appear to have thought that it did.

CERAPTURUS. [PAUSUS.]

CERAPUS (Zoology), a genus of amphipodous crustaceans forming the sixth division of the third section of the order *Amphipoda* (Latreille), according to Desmarest. The following are the characters of this division: all four antennæ very great and strong, and nearly of the same length; the upper with four joints, the lower or lateral ones with five.

Say first established this genus, which has the antennæ hairy and performing in some sort the office of limbs, herein corresponding in a degree to the lower antennæ of the *Corophia* of Latreille. Feet of the first pair small, and terminated by a simple short nail; those of the second pair, on the contrary, very large, having a large, flat, triangular manus provided with a biarticulated thumb, corresponding to a well developed point which represents the immovable finger in the ordinary crustaceans; those of the three succeeding pairs moderate and monodactylous, and the four last longer, more slender, and directed backwards and upwards. Body long, linear, demicylindrical, composed of twelve segments, the last of which is flattened into the form of an oval plate furnished on each side with a small bifurcated appendage at the extremity. Head terminated by a very small rostrum. Eyes projecting. Example, *Cerapus tubularis*. Like the larvæ of the *Phryganæ*, this extra-

ordinary crustacean, which is about six lines in length, lives in a small cylindrical tube, which is considered to be that of a *Tubularia*, exposing only the head, the four large an-

* We have found *Cerambyx* larvæ, which, judging by the size of the insects to which they afterwards turned, were full-grown: these have been kept for upwards of a year without increasing in size in the slightest degree.

† See Kirby and Spence's *Introduction to British Entomology*.

‡ The above definition of an incomplete pupa must only be taken in a comparative sense. The parts are not closely applied to the body, but not so much so as in the pupæ of the *Lepidoptera*.

and the two first pairs of feet. The species occurs in abundance in the sea near Egg Harbor, in the United States, in the midst of *Sertularia*, which is supposed to form its principal food. (See *Journal of the Academy of Naturalists of Philadelphia*, vol. i., p. 49, pl. 4.)

RASIN, a peculiar gum, which exudes from cherry and plum-trees. The gum from the stem of *Prunus Avium* is stated to consist of

Cerasin . . .	80
Gum . . .	20

100

Externally, rasin resembles gum arabic, but its properties are different. When treated with water it leaves much undissolved mucilage, and its solution is not so viscid as that of gum arabic. It is not completely precipitated by alcohol, and the subacetate of lead occasions in 24 hours a precipitate in fine filaments. It is not coagulated by persulphate of iron, but this salt sometimes discovers the presence of gallic acid; it is not rendered turbid by solution of silicate of potash, nor by protonitrate of mercury, but with perchloride of tin it forms a stiff gelatinous coagulum. Neither cerasin nor gum arabic is precipitated from solution by infusion of galls. The above account is from Berzelius (*Traité de Chimie*, tom. v.). The more recent experiments of Guerin (*An. de Chim. et de Phys.* 49) assign somewhat different properties to cerasin; he states its specific gravity to be 1.475, that by boiling in water it is totally soluble, and the solution is precipitable by alcohol. The following is stated by Guerin as the composition of cherry-tree gum—

Water . . .	12.00
Ashes . . .	1.00

CERASTES. [VIPERS.]

CERASUS, a genus of hardy trees, belonging to the Amygdaleous division of the natural order Rosaceæ, and including the common Cherry among its species. It is hardly different from *Prunus*, there being little or nothing to distinguish it beyond its leaves when young being folded flat, instead of being rolled up; botanists seem however pretty well agreed in looking upon the cherries as a genus distinct from plums, and we follow their example. The species may be divided into the True Cherries, the Bird-cherries, and the Cherry Laurels. What species are known in gardens will be briefly mentioned under each head.

Section I. True Cherries. *Flowers growing in umbels or singly, or occasionally in short corymbs; usually appearing earlier than the leaves.*

1. *C. avium*, the Wild Cherry. Flowers appearing with the leaves, which are pale and rather downy underneath. Branches when young weak and spreading. Fruit roundish, soft flesh and an austere juice. A native of the woods of Europe and the west of Asia; and in a cultivated form common in gardens; in this country it occurs as far to the north as Ross-shire, where it exists in the form of a dwarf bush propagating itself rapidly by the roots. The wood is remarkable for the large size of its medullary processes, which give its longitudinal section a bright satiny lustre, and render it well suited for ornamental cabinet

In this respect it is much superior to the *C. vulgaris*.

When growing in gravelly or sharp sandy situations with a bottom, which are the only localities where it thrives, it is a very considerable size, occasional specimens being spoken of as much as 80 feet, and more in height; it is however more commonly seen in the state of coppice wood. To this species we presume all the weeping or weak-branched cultivated cherries with an acid juice are to be referred either as genuine varieties or hybrid forms; such are the *Merisier*, *Merisier*, *Morello*, *Kentish* and *All Saint* or *ever-flowering cherry*, which last is often made into a species by systematic writers, and called *C. semperflorens*. Some of the varieties, especially the double-flowered French, as it is commonly called, the double *Merisier* of the French, are remarkable for their elegance and beauty. *C. avium* is the *Cerasus sylvestris* of Ray, and the *C. marasca*, or *marasche* cherry of Dalmatia, from which maraschino is prepared, has no specific marks to distinguish it.

2. *C. vulgaris*, the common cherry. Flowers appearing

than the leaves, which are light green and smooth beneath. Branches when young stiff and erect. Fruit roundish or heart-shaped, succulent, more or less firm, and sugary. Found wild in the woods of Asia Minor, where it requires a very large size. Walsh speaks of it as being still common along the northern coast of Asia Minor, whence the 'original cherry' was brought to Europe. One variety is chiefly seen in gardens, the other grows in woods in the interior, particularly on the banks of the Sakari, the ancient Sangarius. The trees attain a gigantic size; they are assailed by perpendicular trunks suspended from the lowest branches. Walsh measured one of them 5 feet in circumference (?), 40 feet to the origin of the lowest branches, and from 90 to 100 feet in full height; this large tree was loaded with delicious, fine, transparent, amber-coloured fruit. Mr. Royle considers the cherry wild in Cashmere. It was introduced into Europe by the Romans under Lucullus, about half a century before the birth of Christ, and has ever since formed one of the most esteemed varieties of dessert fruit. It differs from the genuine form of *C. avium* in the characters above assigned to it, as also in its wood having such small medullary processes that nothing like a satiny appearance in it is produced, whatever the direction be in which it is cut; hence its grain is plain and it is but ill suited for cabinet-makers' work. It is to be presumed that this exotic species is the origin of the sweet large cherries called Bigarreaux, Guignes, and the like, to which must undoubtedly be added the Tartarian cherries of the English gardens. That the two species now enumerated were really distinct in the beginning we have little doubt; but long cultivation and their intermixture by hybridizing, either intentional or accidental, has so confused them that the gardens are filled with intermediate races, and their limits are lost sight of.

It is here that the *C. juliana* and *duracina* of modern botanists have to be referred; while their *C. cagroniana*, or acid succulent cherries, are probably hybrids. [CHERRY.] For a full account of these species, see Loudon's *Arboretum Britannicum*.

3. *C. chamaecerasus*, the ground cherry. Flowers in umbels, either with the leaves or earlier. Leaves obovate-lanceolate, shining, crenated, quite smooth, with few or no glands. Fruit spherical, acid, with stalks longer than the leaves. A dwarf species, never rising above three or four feet high, and in the gardens usually budded on the common cherry at the height of five or six feet from the ground. It is not ornamental, and is seldom seen. Its native situations are stony, rocky, mountainous places, about the skirts of woods, and in hedges in the eastern parts of Europe and west of Asia; it is common in Lower Austria and Hungary. Gmelin met with it in Siberia, and Ledebour, in the Kirghis desert, near Karkaraly, in the Altai.

4. *C. nigra*, the black American cherry. Flowers in sessile umbels, appearing before the leaves; light pink. Leaves obovate-oblong or obovate-lanceolate, often cuspidate, somewhat doubly serrated, with or without two glands at the base, slightly rugose. Segments of the calyx toothed. Native of the northern states of the North American Union, and extending into Canada and Newfoundland. It forms rather a handsome tree, with its loose umbels of pinkish flowers. The fruit is as large as a moderately sized cherry.

5. *C. Pennsylvanica*, Pennsylvanian cherry. Flowers in sessile umbels, appearing along with the leaves. Leaves ovate or oval, sharp-pointed, smooth, and rather shining, with minute unequal toothings. Segments of the calyx toothless. A native of the more northern parts of North America, especially in Canada, where it is common. It forms a small tree very like *C. nigra* in some respects, but differing from that species in its much smaller colourless flower and smooth rather shining leaves, which never acquire the obovate figure so common in *C. nigra*. The fruit is that of a bird-cherry, and is said to be sweet. *C. borealis* is considered by Sir William Hooker as being identical with this. It is represented in the southern states of the American Union by *C. umbellata*, which appears to differ chiefly in having spinous branches, more finely serrated leaves, and downy calyxes.

6. *C. serrulata*, fine-toothed cherry. Leaves oblong-lanceolate, obtuse at the base, tapering to the point, bordered with fine bristle-pointed teeth, thin, and not shining. A native of China, and only known in our gardens with double flowers. These are exceedingly delicate and beautiful, but they appear at so early a season as to be liable to injury from the spring frosts.

7. *C. pseudocera*. hairy loose corymbs, long hairy tube to the calyx. Leaves ovate or obovate, cuspidate, doubly serrated, slightly downy on the veins. Chinese species, probably from the northern provinces that great empire. It bears a small pale red sweet fruit which is more readily forced than that of the common cherry. It grows readily in the open air, forming a large bush, and producing its pale pink flowers in the beginning of March; on this account they are sometimes destroyed by frost. For some particulars concerning the cultivation of this species, see the *Transactions of the Horticultural Society*, vol. vii., p. 180, old series.

8. *C. depressa*, sand cherry. Flowers appearing a little earlier than the leaves, or about the same time, in small compact umbels. Leaves obovate-lanceolate, serrated, glaucous on the under side, bluish green and somewhat shining on the upper. Fruit mucronate. A small bush resembling a dwarf almond, covered with profusion of small white flowers in May, and afterwards with small, black, bitter, shining, sharp-pointed fruit. It is found in Canada and the northern of the United States, but appears to be unknown in the southern States. In our gardens it is a handsome bush, but short-lived. The nurserymen propagate it by budding on a plum-stock.

9. *C. prostrata*, the spreading cherry. Flowers solitary, or few in a cluster, appearing along with the leaves, than which they are shorter. Leaves roundish-ovate, loosely hairy beneath, deeply and simply serrated. Calyx-tube oblong, segments downy inside. A small prostrate bush, found on the sea-coast of Candia and on the mountains of Dalmatia and Asia Minor, where it enlivens the rocks with its gay pink blossoms late in the spring. In this country it is rare; it will live without protection in winter, but it prefers a moderate degree of shade, and is admirably suited for rockwork in sheltered places. Botanists are pretty generally of opinion that it is the same as what the Russians call *Amygdalus incana*, a species inhabiting the lower grounds of the Caucasian range; but in this we are persuaded they are wrong, for the *A. incana*, whether it be an almond or a cherry, forms a bush five or six feet high, and has narrow, oblong, blunt leaves, covered beneath with as close a down as those of *spiraea tomentosa*.

10. *C. Japonica*, the dwarf almond. Leaves ovate-lanceolate, very much tapering to the point, finely serrated, slightly downy beneath, very rugose. Flowers appearing a little before the leaves in small dense clusters. Calyx smooth, bell-shaped, with the segments as long as the tube. A native of Japan, and long known in our gardens as the double dwarf almond, one of the most beautiful objects that appear in the month of March. Its flowers in their double state are of a pale pink, with the delicate petals arranged with the most artificial symmetry, so as to resemble curious shell-work. Although quite hardy, yet this species should be trained to pales or walls, so as to be sheltered from the frosts that are so common at the early season when its flowers appear. The single-flowered plant has only been lately introduced, and is at present rare; the flowers are small, and not remarkable for their beauty. The fruit is a small, pale, red, acid cherry, not much larger than a pea.

*Section II. Bird Cherries. Flowers growing in long racemes, appearing with, or later than, the leaves. Leaves deciduous.

11. *C. Mahaleb*, the perfumed cherry. Leaves roundish ovate, deciduous, glaucous on the underside, simply serrated. Flowers in somewhat corymbose racemes not much longer than the leaves. A shrub or small tree, remarkable for the powerful and agreeable odour of its flowers. It is a love of rocks in the Tyrol, Dalmatia, Carniola, and Hungary, spreading into Asia till it acquires its most eastern limits in the woods and hedges of the southern parts of the Crimea. It is not a particularly ornamental plant, and though perfectly hardy is seldom seen in our gardens. The fruit is black, and nauseously bitter.

12. *C. Padus*, the common bird cherry. Leaves oblong, cuspidate, rugose, simply serrated, deciduous. Flowers in racemes much longer than the leaves. A common species, wild in the woods and hedges of the middle parts of Europe, less common in the south, and occurring on the mountains of Caucasus and the Altai. It is readily known by its deciduous rugose leaves, long racemes of white flowers

and round bitter fruit, which is however agreeable to birds. Two or three unimportant varieties occur in China; and also one with red fruit (*C. Padus rubra*), leaves of which are less rugose and more lucid, longer, and not cuspidate. It looks like a hybrid between *P. lus* and *C. Virginiana*. This species is common in the woods, and makes good underwood in plantations that are cut periodically.

13. *C. Virginiana*, the choke cherry. Leaves ovate or oblong-lanceolate, acuminate, serrated, flat, very smooth, shining, deciduous. Racemes long, cylindrical, lateral. In all systematic books are named two American bird cherries, *C. Virginiana* and *C. serotina*, to each of which are assigned characters that comprehend so little of a discriminative nature, that we find it impracticable to ascertain whether the two species have really been before the writers on these subjects, or whether they have not distinguished, under different names, specimens of one and the same species. A suspicion of this kind has evidently come across the mind of more than one botanist, and it is highly probable that the whole of what is said respecting geographical distribution, uses, &c., is as applicable to the one as the other. As these particulars, at all events, refer to the common American bird cherry, a plant to which the preceding definition strictly applies, we have considered that to be what is meant by *C. Virginiana*; and we have applied the name of *C. serotina* to a plant which occurs in our gardens, and which probably is a different species, although closely allied to the present. Sir W. Hooker makes the following statement concerning *C. Virginiana*. This forms a large tree, according to Michaux, in the southern states, attaining from 80 to 100 feet in height. It is the Tawquoy-moen-ahik of the Crees, according to Dr. Richardson, rising on the sandy plains of the Saskatchewan to 20 feet, but extending as far north as the Great Slave lake (lat. 62°), where it attains the height of five feet only. Its fruit is not very edible in a recent state, but when dried and bruised it forms an esteemed addition to pemmican. Elliott adds, that its timber is among the best in the United States for cabinet-makers' work. In this country it forms rather a graceful, though roundish headed tree, from 20 to 30 feet high; and its shining though deciduous leaves give it almost the appearance of an evergreen.

14. *C. serotina*, the late bird cherry. Leaves obovate-lanceolate, acute, serrated, channelled, very shining, deciduous. Racemes long, cylindrical, lateral. What is thus designated in this place is a plant with something of the aspect of a Portugal laurel, and as it flowers later than the last, its fruit is usually ripened in this climate. It is principally distinguished by its leaves being more obovate, never flat, but always half-folded up, and with a more shining surface.

15. *C. Capollim*, Mexican bird cherry. Leaves ovate-lanceolate, acuminate, serrated, flat, shining, deciduous. Racemes terminal. A native of the mountains of Mexico, and well distinguished by its taper-pointed leaves, and terminal racemes. It is not apparently distinct from the *C. salicifolia* of Peru. In this country it is rather tender, but forms a handsome object when trained to walls or palings. Its bark is reputed a valuable febrifuge.

Section III. Laurel Cherries. Flowers growing in long racemes, appearing with the leaves. Leaves evergreen.

16. *C. Caroliniana*, the Carolina laurel cherry. Leaves oblong-lanceolate, acute, serrated, and entire, evergreen. Racemes lateral, much shorter than the leaves. An uncommon species in the collections of this country, from the climate of which it is not adapted. It is said to be one of the most ornamental trees of Carolina, where it grows on islands and along banks of rivers, from 30 to 50 feet high, with a regular oval head. Its leaves are very poisonous, and frequently in the spring of the year destroy cattle that are tempted to browse freely on them.

17. *C. lauro-cerasus*, the common or broad-leaved laurel (cherry). Leaves oblong-lanceolate, remotely serrated, somewhat convex, pale green, evergreen. Racemes shorter than the leaves. This valuable and common evergreen which now gives half their richness to the varied pleasure grounds of Great Britain; which is so hardy that no frost seems to affect it; which is equally capable of resisting the greatest heat and drought of summer, and which will flourish either in the most exposed or the most shaded situations, is a

native of the country near Trebizond in Asia Minor, and was sent from Constantinople to Ecluse, in the year 1577, by the imperial ambassador Ursinad. DeCuse gives an interesting account of the difficulty he had in establishing the plant, which must have been transmitted as a small charge, for it is said to have been six feet high with a stem as thick as a man's arm. (Chusii, *Hist. Plantarum*, p. 5.) A variegated and a barren leaved variety are known in gardens, but the original kind is the only one worth cultivating as an object of ornament. It is multiplied in the nurseries by layering, cuttings, and seeds. This species is remarkable for the abundance of hydriac acid secreted in its leaves.

18. *C. Lusitanica*, the Portugal laurel (cherry). Leaves ovate-lanceolate, acuminate, concave, dark green, glossy, shining, evergreen. Racemes lateral, longer than the leaves. A native of Portugal, and also found in the Canaries, where it is called *Hixa*, acquiring a height of 60 or 70 feet. According to some the *Hixa* is a distinct species; Mr. Barker Webb found that plant on the Serra de Gerez in Portugal, of the height just stated, while the true *Cerasus Lusitanica* was not above 18 or 20 feet high. This is less hardy than the preceding; it is less easy to transplant, and will not grow so well under other trees: nevertheless, it is one of the most useful of our naturalized evergreens. It produces fruit in abundance in England, from which it is readily propagated.

CERATES, the name given to certain combinations of wax with other substances, which are used as external applications in the treatment of various surgical cases. They are of a degree of consistence intermediate between that of plasters and that of ointments; and, according to the nature of the materials united with the wax, are capable of serving different ends. They may be emollient, when applied to inflamed or chapped surfaces, or stimulating, when applied to indolent ulcers; and in the case of wounds or abraded skin are useful in excluding the air, and preventing the dressings from adhering.

CERATINA, a genus of Hymenopterous insects of the section *Mellifera* and family *Apidae*. Technical characters:—exterior palpi six-jointed, interior two-jointed; antennæ inserted in a little fossula, and terminated almost in an elongated club; mandibles sulcated, and tridentate at the apex; abdomen somewhat ovate, elongate, narrower towards the base, and destitute of a ventral scopa.

This genus is included in the section *Apis* (xx d. 2 a.) of Kirby's 'Monographia Apum Angliæ.'

Ceratina cærulea (*Apis cyaneæ*, Kir.), a little bee which is very uncommon in this country and found during the autumn in the flowers of the Jacobææ, will serve as an illustration of this genus:—it is about a quarter of an inch in length, of a bluish-green colour, and very smooth and shining; the fore part of the head in the male is white.

There is a long and interesting account of the habits of this little insect given by Spinola in the tenth volume of the 'Annales du Muséum d'Histoire Naturelle,' from which the following facts are drawn.

The male *Ceratina* selects the dead branches of the bramble and likewise those of the sweet briar, and with her mandibles excavates the pith, until a cylindrical burrow of considerable length is formed; this is then divided, generally, into eight or nine cells, by partitions formed of the pith which was dislodged, mixed with a glutinous secretion. In each cell is formed, an egg is deposited: it is then furnished with a portion of honey, which serves for the food of the larva.

When the cell is closed, the account is given under the name of *Ceratina albivittata* which is said to be synonymous with the one above-mentioned. Spinola states that the insect is common in the south of Europe.

CERATONIA SILIQUA, St. John's Bread, or the carob-tree, is a remarkable plant found wild in all the countries bordering the Mediterranean, especially in the Levant. It is almost the only tree that grows, which relieves the bitterness of the white stone enclosures by its dark, sweet pulp. It belongs to the natural order Leguminosæ, of which it is singular for the very unusual circumstance of its flowers having no petals. The pods contain a sweet nutritious pulp, and are sometimes seen in the fruiterers' shops in London: they are a common article of food in the countries where the tree grows wild. Pliny calls it *Siquia præducta*. At the present day it is sent from Palestine to Alexandria in ship-loads, and from thence

across the Mediterranean, as far as Constantinople, where it is sold in all the shops. The pulp resembles manna in taste and consistence, and is sometimes used as sugar to serve other substances. But the instance that has rendered it famous is the controversy of St. John the Evangelist, who asserted that the apostles, or at least St. John were some of the fathers of the world honey, the saccharine matter of this pod. It is certain that the plant grows in great abundance in the wilderness of Palestine, where its produce is at this day used for food. It is called by the Arabs *Karob*. (Wash.) The Spaniards call it *algaroba*, and give its pods to horses. The seeds, which are nearly of the weight of a carat, have been thought to have been the origin of that ancient money-weight.

[*Ceratonia Siliqua*.]

CERATOPHRIS. [FROGS.]

CERATOPHYLLÆ, a small and obscure group of plants, comprehending the single genus *Ceratophyllum*, and probably a mere section of *Urticaceæ*, with the structure and habit of that natural order modified by the submerged situation in which the species live. They are aquatic plants, with cellular leaves split into capillary divisions, with monocious flowers, a many-parted inferior calyx, several stamens, a one-celled ovary with a pendulous ovule, and a seed whose embryo has four cotyledons surrounding a highly developed many-leaved plumula. *Ceratophyllum submersum*, and *demersum* inhabit ditches in this country.

CERATOPHYTA. [CORALLIA.]

CERBERA, a genus of Apocynaceæ plants, containing, among other poisonous species, that from which the tangle poison of Madagascar is procured. The genus *Cerbera* is known in its order by the calyx being leafy, the corolla funnel-shaped, with a clavate tube, and five scales on its orifice, the stamens sessile just below the orifice of the tube, and a one or two-seeded drupe, with a fibrous woody stone. The tangle tree, *Cerbera tanghin*, is described as a tree with lanceolate alternate leaves, of a leathery texture, pale pink flowers arranged in corymbose panicles, with a crimson star-like blotch at the orifice of the tube, and an oval drupe as large as a peach, of a green colour, stained with purple, and not unlike some sorts of mango. The following interesting account of the plant is given by Mr. Telfair:—The kernel of the fruit must be a very powerful poison: it is not much larger than an almond, and yet is sufficient to destroy above twenty persons. Radama, the late king of Madagascar, abolished the use of it as an ordeal; whether the custom has been revived by the new government I know not. It was with great difficulty that the chieftains could be persuaded to admit of the abolition of an usage, which had existed from time immemorial, and whose unerring efficacy in the detection and punishment of crime had never been questioned, until Mr. Hasty

our government agent had acquired such an influence with Radama and his court, as to admit of the exposure of fallacy. But this was the work of years; and although Radama was at length himself convinced that nothing could be more unjust than the continuance of the practice, he dared not so far shock the prejudices of his people as order that it should cease. Even the chief performers in the ceremony, the Skids, as they are called at Tananarive, who unite in their own persons the offices of priests and physicians, and who administer the poisonous kernel to the victims, never doubt its power of revealing guilt or clearing innocence; the last occasion on which it was practiced in Radama's reign, and of which he availed himself to effect its discontinuance, personally regarded his court and attendants. The king was affected with a complaint of the liver for which the skid prescribed some inefficacious remedies, and as the disease became worse, Mr. Hasty gave him some calomel in doses, which he had found by experience to relieve himself under similar symptoms. The disease disappeared, but pythalism was produced, and alarmed the king's family, who believed that he was poisoned, and insisted that all his immediate attendants should be put to the ordeal of the tanghin, and the royal skid was most earnest in pressing to have it performed, although he himself, from his rank and place, was among the first to whom it would be administered. In vain the king protested that he felt himself cured, and that the indisposition and soreness of the mouth was caused by the medicines that had relieved him, and which would pass off in a few days. The skid insisted, the ministers and principal chieftains joined with the family in requiring the ordeal, to which the king, in spite of his convictions, was compelled to consent; but at the same time he made it a condition that this should be the last exhibition of the kind, and he bewailed the necessity which deprived him of so many attached dependants, whose fate he had predicted, while he protested his conviction of their innocence.

The king's servants, including the skid, were more than twenty in number; they were shut up at night separately and not allowed to taste food; the next morning they were brought out in procession, and paraded before the assembled people; the presiding skid had the tanghin fruit in readiness; after some prayers and superstitious evolutions he took out the kernel, which he placed on a smooth stone and with another stone broke down part of it into a soft white mass like powdered almonds. The victims were then brought separately forward, each was questioned as to his guilt, and if he denied, his arms were tied behind, and he was placed on his knees before the skid, who put a portion of the pounded kernel on his tongue and compelled him to swallow it. Thus the kernel was shared among all the king's personal servants. On some of the individuals the poison began to operate in half an hour or less. The skid takes particular notice how they fall, whether on the face, to the right or left hand, or on the back, each position indicating a different shade of guilt. Convulsions generally come on, accompanied with efforts to vomit. Those whose stomachs reject the dose at an early period usually recover: on this occasion there were only two individuals with whom this was the case; the others were thrown in a state of insensibility into a hole, and every person present at the ceremony was obliged to throw a stone over them, so that their burial was quickly completed. The king's skid was one of the first that fell. Those that recover are supposed to bear a charmed life ever after, and are respected as the peculiar favourites of the gods.

CERBERUS, the watch-dog of the infernal regions, the offspring of Typhon and Echidna. According to Hesiod he had fifty heads; according to Horace, 100; the ordinary account gives him only three, and this number, which corresponds to the triple form in which Geryon and Hecate appear, points to the usual phenomenon in the elementary worship of ancient Greece, in which a power of the nether world was also a terrestrial and celestial divinity. The Chimæra was another member of the same kind. Cerberus was also the name of a serpent which infested the neighbourhood of Cape Taurinus. The word probably signifies 'dark'; Cerberian occurs as a synonym for Cimmerian in Hesychius. w. Nicander applies it as an epithet to a toad. (Dahler, *ropeez. voc. pe* in.; Steph. *Thes.* ed. Lond. vol. i. p. xxxii.) tains CERBERE (Zoology), a subgenus of Ophidiæ (serpents), established by Cuvier in his division of the great genus *Coluber*. The *Cerberi*, like the *Pythons*, next to which

are placed in the 'Rhone Animal' have nearly the whole of the head covered with small scales, and plates only and before the eyes; but they are without the skin near the vent. Cuvier further says that they have also sometimes simple plates at the base of the tail. He observes that whilst he has seen this arrangement in one individual, he has remarked others of the same species which had them all double; a proof, in his opinion, of the small importance of the character. Example, *Karoo Bokdam*. (*Coluber Cerberus* of D. Russell, who gives the native name above stated, thus describes the species. 'Abdominal scuta 144, subcaudal squamæ 59. The head, somewhat broader than the neck, very small in proportion to the trunk; a little convex above, compressed on the sides, and projecting into a short, obtuse, or subtruncate snout, on which the eyes and nostrils are situated. The snout is covered with small laminae of various forms; the rest of the head with small suborbicular ear-nated scales. The mouth not large, the jaws nearly of equal length. The teeth close set, regular, small, reflex; a marginal and two palatal rows in the upper jaw. The eyes vertical, small, orbicular, protuberant, each situated in the centre of a remarkable circle of small triangular laminae. The nostrils very small, vertical, near to each other, and close to the apex of the rostrum.

[Head of Cerberus.]

'The trunk thick, round, covered with large carinated, broad-oval, imbricate scales. The length three feet four inches and a half; thickness near the head about three inches; the middle of the trunk four inches and a half. The tail measures only eight inches, is a little compressed, tapers moderately, and terminates in an obtuse point.

[Coluber Cerberus.]

Part of the head is almost black; the colour of the trunk and tail very dark grey; the throat, belly, and under part of the tail are of a dusky yellow; but the colour of the scapula seemed to have been changed by the spirit.

Dr. Russell further observes that his specimen, which our figure is taken, was sent from Ganjam in 1783, and that he never saw one alive. He adds that, withstanding its suspicious appearance, the want of poison organs shows that the snake is not formidable.

CERCA'RIA. [MELASCOPTERYX.]

CERCO'RIIS. [HYMENOPTERA, FORMICIDAE.]

CERCIS ALIQUASTRUM, the Judas tree, so called from the tradition that it was upon a plant of it, near Jerusalem, that the betrayer of our Saviour hanged himself, is a leguminous tree, common on the shores of Asia Minor, and in all the East. Dr. Walsh speaks of it as abounding in the Levant at the present day, clothing the shores of the Bosphorus and the sides of Mount Libanus. It is very beautiful in all its stages. Very early in spring, flowers of a bright pale red burst out before any leaf appears, not only from every part of the branches, but from the trunk, piercing the thick strong bark nearly down to the root in a very remarkable manner, and it is for this reason called *red bud*. These buds are gathered and used with other raw vegetables by the Greeks and Turks in salads, to which they give an agreeable colour and taste. It is very common in England, where it proves quite hardy, but it does not flower well unless in a very sheltered situation, or when trained to a wall. There is a pale, almost white, flowered variety, and also an American species (*C. Canadensis*), but neither are worth cultivation.

CERCOCE'BUS. [GUENON.]

CERCOPITHE'CUS. [GUENON.]

CERDAGNE, FRANÇOISE (French Cerdagne), a district ceded by Spain to France, in 1660, in virtue of the treaty of the Pyrenees. Its extent, according to the 'Dict. Univ. de la France,' is about 16 or 17 miles, its breadth about 11 miles. It is a mountainous country, and contains the springs of the Sègre, a Spanish river, and of the Tech or Tetch, which belongs to France. Its capital was Mont Louis. It is now comprehended in the department of Pyrénées Orientales, or Eastern Pyrenees.

CEREOPSIS, a genus of birds established by Latham, and placed by him (1802) among the waders (*Grallatores*); but there is a probability that it was described from a mutilated specimen; for on the republication of his 'General History' (1824), he modified the characters, and though he still kept the genus in the order to which he had already assigned it, he placed it as the last of the series, and next to the swimmers, *Palmipedes*. (*Anseres*, Linn.) Temminck, about the same year in which Latham's republication appeared, figured it in his 'Planches coloriées,' (pl. 206,) and placed it a proper place at the head of the swimmers. Mr. Bennett ('Gardens and Menagerie of the Zoological Society,' a work of considerable research and beautifully illustrated) shows that the bird had been observed by nearly all the navigators who had visited the south coast of New Holland and its neighbouring islands from 1792 downwards.

Generic Character.—Bill short, elevated, obtuse, covered by a broadly expanded cere, except at the extremity, which is somewhat vaulted and truncated. Nostrils large, situated about the middle of the bill, and open. Feet with tarsi (shanks) longer than the middle toe, and bare of feathers above the knees; great toe articulated to the anterior part of the tarsus; anterior toes palmated, and armed with membranes deeply notched or cut out as it were, so as to appear scarcely to reach beyond the half of their length; nails long and strong; wings ample; wing-coverts nearly as long as the quills; first quill a little shorter than the succeeding ones. Tail-feathers sixteen.

The only species known is *Cereopsis Nova Hollandiae*, about the size of the common goose and nearly of the same carriage, with the exception of the length of the legs. Temminck gives the length at from two feet and a half to three feet. We select Mr. Bennett's description because it rectifies the oversights in Temminck's—oversights which may possibly be accounted for from the latter having written his description from a skin, or at most from a preserved bird, whereas Mr. Bennett's description accords with our own observations. A red patch on the top of the head is of a dull red, and the rest of the plumage of a dingy grey, deeper on the upper than on the under parts, having the extremity of each of the feathers of the back

marginated with a lighter band, and most of the wing-coverts and secondary quill-feathers marked with rounded dusky or black spots two to four lines in diameter. On the feathers of the back and shoulders the spots are much larger, assume an angular or subangular form, and approach more nearly the general colour of the plumage. The quill-feathers both of the wing and tail are dusky black throughout the greater part of their extent. The naked extremity of the bill is black; the broadly expanded cere of a light straw or lemon colour; the irides light hazel; the naked part of the legs reddish orange; and the toes, together with their web and claws, and a streak passing for some little distance up the fore part of the leg, black.

Anatomy.—At a meeting of the 'Committee of Science and Correspondence of the Zoological Society,' January 26, 1831, Mr. Yarrell stated* that having examined the body of an individual which had died at the society's menagerie in the Regent's Park, he had remarked that its trunk was much shorter than that of the true geese, and more triangular in its shape; the pectoral muscles were large and dark coloured. The trachea was of large but nearly uniform calibre, without convolution, and attached in its descent to the right side of the neck, as in the heron and bittern; in the form of its bone of divarication and bronchiae, it most resembled the same part in the geese. The muscles of voice were two pairs; one pair attached to the shafts of the os furcatorium, the other to the inner lateral surface of the sternum. The lobes of the liver were of large size, morbidly dark in colour; their substance broke down under the finger on the slightest pressure. The stomach, a true gizzard, was of small size as compared with the bulk of the bird. The first duplication of intestine was six inches in length, at the returning portion of which the biliary and pancreatic ducts entered; from thence to the origin of the caeca, four feet six inches; the caeca, nine inches each; the colon and rectum together, five inches; the whole length of the intestines was seven feet five inches. The stomach and intestinal viscera were loaded with fat; the other parts exhibited nothing remarkable.

Internally this bird, which was a male, resembled the true geese; but externally, in the character of the bones, particularly in the rounded form of the edge, and great depth of the keel of the sternum, and the lateral situation of the trachea in reference to the cervical vertebrae, it was decidedly similar to the *Ardeidae* (herons).

Mr. Yarrell availed himself of the occasion to remark, that the *Natatores* (swimmers) of Mr. Vigors's systematic arrangement in ornithology were placed between the *Grallatores* or waders on the one side, and the *Raptores* or birds of prey on the other; and that the order contained five groups, two of which, the *Alcedae* and *Columbidae*, were called normal, containing those birds which were considered to be the types of the true swimmers, and three groups, *Anatidae*, *Pelecanidae* and *Laridae*, called aberrant, as deviating from the type, and exhibiting some characters which connected them either with the *Grallatores* or the *Raptores*. Some of the *Laridae* and *Pelecanidae* in the length of their wings, their consequent power of flight, and the mode of their taking their food in the air, exhibited their obvious affinity to the birds of prey on the one hand; while some of the *Anatidae*, by their lengthened legs and neck, and their habit of passing much of their time on land, or frequenting shallow pools of water, showed an equal affinity to some of the waders. This was the case with the *Cereopsis*, and occurred also in the semipalmated goose, and in another goose then living in the Society's Gardens, the *Anser jubatus* of Spix. It was stated that in proportion as these birds departed from the character of the true geese in their external appearance, and habits, and in both approached to the *Ardeidae*, they would also be found on examination to resemble them in their internal organization. In proof of this, an extensive series of parts of the skeletons of birds from the true divers to the cranes was exhibited, and the peculiarities pointed out. The keel of the breast-bone in the ducks and true geese was shown to be of considerable depth, with its inferior edge nearly straight; those of the semipalmated geese and *Cereopsis* were shown to be much deeper in the keel, and the inferior edges much more convex; and comparison with the same parts from the spoon-bill, herons, bitterns, and storks, showed the approximation to the *Ardeidae* in form. The peculiarities of the whole series indicated, between the two extreme points the

development of the power of flight, as contrasted with the maximum of the power of diving, in a succession of characters as easily recognizable in the skeleton as in the external appearance of the birds themselves, and supplied a valuable auxiliary chain of affinities to assist the naturalist in his views of arrangement.

Habits. See Mr. Bennett's observations (1831), in 'The Gardens and Menagerie' above quoted, that 'M. Temminck states that we have as yet no positive information with regard to the manners, habits, and mode of feeding of the *Cereopsis*; but this assertion falls to the ground, now that we have ascertained that the bird has been noticed by so many travellers. It is true that the limited opportunities that have occurred of observing it in a state of nature, have precluded the possibility of obtaining a complete history of its habits and mode of life; but the accounts furnished by various writers lead directly to the inference that it resembles the wild geese of the northern hemisphere as closely in those particulars as in general conformation. We cannot state with certainty whether it is equally migratory; but Captain Flinders, who found it at one period of the year so abundant on Goose Island as fully to justify the appellation, adds that it was by no means so numerous at a different season, and this fact necessarily implies at least a partial change of locality. In its manners it appears that it is by no means so shy as our northern geese, a circumstance which probably depends on the little disturbance that it has hitherto met with in its native haunts. Labillardiere tells us that many of those first seen by him suffered themselves to be taken with the hand; but the rest becoming apprised of their danger, speedily took to flight. Considerable numbers were taken by the crew of Captain Flinders's vessel, both at Lucky Bay and Goose Island, by knocking them down with sticks, and some of them were secured alive. According to M. Bailly those seen by him at Preservation Island evinced so little shyness, and suffered themselves to be approached so readily, that his boat's crew were enabled to procure without any trouble a sufficient quantity to victual them during their stay. The flesh of these geese, as they are called, is described by Bass as being excellent. D'Entrecasteaux considered it much more delicate than that of the European goose; and Flinders adds that on Preservation Island it formed the best repasts of his men. Mrs. Lewin simply states that it is well flavoured.'

'It would seem that this bird does not often leave the coast to visit the interior of the country, for M. Riche, who was lost by his companions for more than two days at Esperance Bay, never met with it in the course of his wanderings in search of them. M. Bailly states that on Preservation Island it takes up its abode on the grassy declivities; and Captain Flinders found it on Goose Island, amongst the grass and on the shore: "it feeds," he says, "upon grass, and rarely takes to the water." Its usual weight is from seven to ten pounds. According to Mr. Bass, it has a deep, hoarse, clanging, and though a short, yet an infected voice; and to the accuracy of this observation we can ourselves bear testimony.'

'With regard to its domesticated habits little is known. Judging from Mrs. Lewin's communication to Dr. Latham, it would appear that it had at one time been introduced into the colony as a denizen of the farm-yard; for that lady stated, "that with management it becomes very tame and familiar, so as to be domesticated with our common goose." But its cultivation seems now to have been entirely abandoned, for we do not observe any notice of it in the numerous works treating of the colony that have been published of late years; and MM. Quoy and Gaimard, the naturalists of a late French expedition which made a considerable stay at Port Jackson, expressly mention having seen a single superb specimen of this very rare bird feeding upon grass in the governor's garden.'

'The four living specimens in the Society's Garden, together with four others at present at the farm on Kingston Hill, formed part of the extensive collection kept by his late Majesty in the Great Park at Windsor. They bred there as freely as the others or any of the other animals of New Holland, and are all descended from one pair originally brought to this country. They are perfectly tame, and in their behaviour closely resemble geese, but show more disposition to become familiar. There can be little doubt that they exceed in number all the stuffed specimens that exist in public collections in Europe; the latter, so far as we are aware, being limited to one in the British, one in

the Paris, and one in the Berlin museums. Our drawing was made from a pair which were kept in the Zoological Society's Garden in the Regent's Park, London.

[*Cereopsis Nova Hollandia.*]

CERES, a planet, discovered by Piazzi on the first day of the present century (January 1, 1801), at Palermo. It was called by him Ceres, after the name of the tutelary goddess of Sicily, and for analogy with the names of the other planets. His first appellation was Ceres Ferdinanda, in honour of the reigning sovereign, but his contemporaries dropped the adjective.

It was suspected by Kepler that some planet existed between Mars and Jupiter, which was an idea derived from observing the mean distances of Mercury, Venus, the Earth, Mars, and Jupiter from the sun, which are as

39, 72, 100, 152, and 520.

The greatness of the interval from 152 to 520 led to the suspicion, which is rendered remarkable by its verification.

The discovery of Uranus by William Herschel, in 1781, put astronomers on the alert, and disposed them to think that the number of the planets was not even yet complete. Piazzi, in forming his large catalogue, examined each new star for several successive evenings before inserting it, and Delambre was in the habit of doing the same. An association of twenty-four astronomers was formed by Delambre, who were to divide the heavens among them, and hunt every corner for moving stars. Piazzi however was the first who succeeded. On the evening above mentioned he was searching for a star marked in Lacaille's zodiacal catalogue, and found that it was accompanied by another of the eighth magnitude. He set himself accordingly to determine its place, and following his usual practice, he found, by observing it on the second and third of the month, that it had a decided motion. He followed its course till the twenty-fourth of the month, when he was interrupted by illness, and by the time he was able to resume his observations the planet was lost in the rays of the sun. In the meanwhile he communicated the discovery throughout Europe; orbits were calculated from the observations he had made by M. Olbers, Burckhardt, and Gauss, and the planet was found again on December 31, by De Zach, and by Olbers on the day following. It was at first supposed to have been a comet; and Piazzi himself was of that opinion for some time. The stimulus given by this discovery was the cause of the almost immediate discovery of VESTA, JUNO, and PALLAS, all moving in orbits very close to each other and to that of Ceres, which comes between Juno and Pallas.

Ceres is a telescopic object, varying its appearance, according to its distance from the earth, from the seventh to the eighth magnitude. Its apparent size is very small, and its magnitude must be considerably less than that of our moon, but how much has not been well settled. The elements of its orbit are as follow

Mean distance from the sun that of earth being unity	9797945
Revolution in mean solar days	16813931
Mean synodical revolution in days	466'62
Mean daily motion	12' 50" '9
Latitude of perihelion January 1820	147° 7' 31" '4
Yearly increase of ditto	121" '3
Inclination of the orbit, January 1 1820	10° 37' 26" '2
Yearly decrease of ditto	— 0" '44
Longitude of node, January 1, 1820	80° 41' 24" '1
Yearly increase of ditto	1" '5
Excentricity	078439
Greatest equation of centre	8° 59' 42" '1

For an annual ephemeris, see the *Nautical Almanac*.

CERET. [*Pyrenæes Orientales*, Department of.]

CERIA, a genus of Dipterous insects of the family *Syrphidae*. Technical characters:—head longer than the thorax; antennæ longer than the head, inserted on a petiole, the second and third joints forming an oval mass; stylet terminal and short; abdomen cylindrical; submarginal nervure of the wings much bent, and throwing out a rudiment of another nervure.

But three species are known of this genus; the colouring is black and yellow, which, together with an elongated and somewhat ovate form of body, gives them a resemblance to wasps. Only one of the three has been discovered in England, and that is extremely rare—it is the *Ceria conopsoides*, and is about half an inch long; black, front of the head yellow in the male, black and yellow in the female; petiole of the antennæ elongated and yellow beneath; sides of the thorax with yellow spots; scutellum yellow, with the apex black; the second, third, and fourth segments of the abdomen, with their margin, of the same colour; legs yellow; exterior margin of the wings brown.

This species appears not to have been found abundant anywhere; the other two differ but slightly from the one just described.

CERIGO, the ancient Cythra (*Κύθηρα*), one of the seven Ionian islands, lies south of the coast of the Morea, 13 miles S.W. of Cape Malca, and 25 miles E. of Cape Ténarus, now called Matapan, and at the entrance of the Gulf of Laconia. Its south extremity is about 45 miles N.N.W. from Carabusa, the nearest part of Candia. Cerigo is of an oval though irregular shape, and about 20 miles long from N. to S., and 10 miles in its greatest breadth. The island is mountainous and rocky; but there are several small valleys and dales, where the soil is fertile and well cultivated. It produces excellent grapes (of which good wine is made), oil, oranges, lemons, and other fruit, sufficient corn, and some cotton. Cerigo is better stocked with cattle than any of the other Ionian islands: it reckons about 3000 horned cattle, 16,000 sheep and 4000 goats, besides 1100 asses, and about 150 horses. (*Neugebauer, Ionische Inseln*.) The inhabitants, by the official returns of 1833, were 8759, distributed in two market-villages and twenty-nine hamlets. The area of the island is 116 English square miles, including the little island of Cerigotto, which lies halfway between it and Candia. There are at Cerigo 9 free-schools, and 1 by the government and attended by above 380

The principal town, or rather village, of Cerigo is Capsali, on the south coast. On the east coast is the village of S. Nicos, with the best anchorage in the island. In the neighbourhood are a number of ancient tombs cut in the rock; and not far from them are some remains of walls, substructures, and broken pillars, supposed to be the relics of ancient Cythra, and of its celebrated temple dedicated to Venus. The spot is called Palæo Castro. On the west coast of the island is Porto Delfino, a large but unsafe natural harbour. Cythra is supposed to have been originally colonised by the Phœnicians. The Lacedæmonians early took possession of it, as it lay conveniently for the protection of their own coasts, as well as a port for vessels coming from Egypt and Africa.

In the Peloponnesian war, the Athenians invaded Cythra, took Scania on its S. coast, and afterwards attacked the town of Cythra, which they took, after some resistance, and carried off its inhabitants. (*Thucydides*, iv. 54.) It was

retaken by the Lacedæmonians. Afterwards it was taken possession of by the Macedonians, and lastly by the Romans. In the twelfth century of our era it was subject to the despots of the Morea, and was lastly taken by the Venetians, who kept possession of it till the fall of their republic. It now forms one of the Ionian Islands under English protection. A detachment of English troops does garrison duty at Cerigo, besides which there is a native militia.

CERINTHUS, whence the word 'Cerinthians,' by which his followers were denominated, was by descent a Jew, and born not many years after, if not before, the death and ascension of Christ. His family appears to have been one of those who were settled without the limits of Palestine towards the north. Perhaps he studied in the schools of Alexandria. But of his own history little is known, and the preservation of his name and memory is owing to certain peculiarities of opinion, by which he was distinguished from other followers of Christ, having led to the mention of him in the writings of some of the earliest Christian fathers, and in catalogues which were early formed of Christian heretics. The fathers who especially notice him are Irenæus, Epiphanius, and Theodorot.

Cerinthus was one of those persons, who looked upon the doctrine of our Saviour as not intended to supersede the doctrine of Moses and the Scribes, but to be engrafted upon it, and when perfectly received to be taken in union with the doctrine and institutions of his own nation, even to the point of circumcision. This opinion prevailed very extensively in the first age of the church, as is evident from much of the New Testament. But Cerinthus had some notions more peculiar concerning the creation of the world and the person of Christ. Departing from the simplicity of the Mosaic doctrine, that 'In the beginning God created the heavens and the earth,' he maintained that the creation was the effect of some angelic virtue, to use the almost unintelligible phrase of the self-called philosophy of that age and nation. He maintained that Jesus of Nazareth was the son of Joseph and Mary, and that at his baptism the Christ, the Son of God, descended upon him in the form of a dove, and became united to him, and that thus it was that Jesus became acquainted with the great unknown Father, and was empowered to work miracles; that at the crucifixion Jesus only suffered, while Christ remained untouched, and leaving Jesus returned to heaven. These opinions are attributed to him by Irenæus, a very early Christian writer. Authorities less respectable represent him as having denied the resurrection, and as having taught men to expect the reign of Christ for a thousand years on earth, when the saints should delight themselves in all terrestrial enjoyment.

However, he seems by common consent to have been placed among those who held singular opinions in the Christian church, called Heresies. Epiphanius names him as one of those who opposed St. Peter and St. Paul. St. John the apostle and evangelist is also said to have personally opposed him. The following story is told. The baths in ancient times were places of public resort: St. John, being at Ephesus, repaired to the bath, but happening to find there, he left the place without bathing, observing to his friends, that it was proper to leave it lest the building should fall, so great an enemy to the truth as Cerinthus being within it. This anecdote is related by Irenæus, who says they who told him had it from Polycarp, a contemporary and friend of St. John. Such an anecdote is important, not so much on account of itself as of the way in which it has been transmitted; showing how the writers of the New Testament, and the persons named in it, are connected with the writers and persons of the succeeding age, and they again with the men of the age succeeding them. Irenæus also says that St. John wrote his Gospel with the express intention of confuting the errors of Cerinthus.

The reader may consult Conyers Middleton's works, vol. ii., p. 107-120, for an examination of this anecdote about St. John and Cerinthus, which he endeavours perhaps unsuccessfully to discredit.

CERIOPORA. [*Milleporidae*.]

CERITHIUM. [*Extomostomata*.]

CERURIUM, a peculiar metal discovered, in 1804, by Hisinger and Berzelius, is a mineral previously confounded with wolfram, and now called *cerite*.

Cerium is not easily obtained in the metallic state by

The usual process, the oxide being with great difficulty reduced by charcoal; it is best procured by decomposing the chloride by potassium. The properties of cerium are that it is pulverulent, its colour varying from deep chocolate brown to rose-red, and by friction it acquires a greenish shining appearance. This powder however does not conduct electricity, and by exposure to the air it emits a smell of hydrogen and its colour becomes gradually paler. When heated, it burns long before redness. It decomposes water readily, even at 32° Fahrenheit; and in boiling water the effervescence is brisk, owing to the evolution of hydrogen gas. Cerium inflames in the vapour of sulphur and gaseous chlorine, but is not acted upon by the vapour of phosphorus.

Oxygen and cerium combine to form two oxides. The protoxide consists of nearly

1 equivalent of oxygen	8
1 " cerium	46

Equivalent 54

It does not form neutral salts with acids, nor does it combine with alkalis. This oxide has not yet been obtained dry or anhydrous; in the state of hydrate it is white, and insoluble in water. By calcination, the water is readily expelled, and the residue is a mixture of the protoxide and peroxide of cerium. When the moist hydrate is exposed to the air it quickly changes, by absorbing carbonic acid and oxygen; and there are formed protocarbonate and hydrate of the peroxide.

Sesquioxide of cerium is composed of

1½ equivalent of oxygen	12
1 " cerium	46

Equivalent 58

It is of a brick red colour, and appears to be infusible, and is undecomposable by heat. It combines with acids, and forms salts, which have always an acid reaction when they are soluble in water. The hydrate of the peroxide is of a bright yellow colour, which becomes deep yellow by heat, and is easily decomposed by it. It is not dissolved either by ammonia, potash, or soda; but the alkaline carbonates dissolve a little, and become of a yellow colour.

Chlorine and cerium combine, and the compound is a white porous mass, which is fusible at a red heat, and is soluble in water. It is composed of

1 equivalent of chlorine	36
1 " cerium	46

Equivalent 82

Bromine and cerium probably form two compounds. When the oxide of cerium is dissolved in hydrobromic acid, a colourless liquid is formed, which, when evaporated to dryness, gives out hydrobromic acid; it afterwards softens into a viscid mass, and again becomes dry. When this is heated to redness, a little bromine is given out, and there remains an insoluble oxybromide of cerium. The pure bromides appear to be obtained with great difficulty.

Fluorine and cerium.—This compound occurs at Finbo with orthite. It is crystallized in regular six-sided prisms. It appears to be a protofluoride. A pure perfluoride also in nature in a state of purity; an oxyfluoride is met with.

Sulphur and cerium combine to form probably two compounds. That which is best known is composed of

1 equivalent of sulphur	16
1 " cerium	46

Equivalent 62

When the sulphuret is procured by the action of sulphuret of carbon it is of a cinnamon red colour; but when by sulphuret of potassium, it is in small transparent yellowish green crystals or scales, which resemble aurum musivum in appearance. The composition is however similar in both cases.

At a heat below redness sulphuret of cerium inflames, gives out sulphurous acid, and subsulphate of cerium remains. It is acted upon by nitric acid, and sulphur is deposited. Muriatic acid evolves sulphuretted hydrogen; chlorine acts readily upon it, but neither iodine, phosphoric acid, nor potassium decomposes it. Sulphuretted hydrogen does not act upon the solutions of cerium; but the soluble sulphurets decompose the solution of the chloride, and throw down a white precipitate, which is a hydrated sulphuret; with the persalts of cerium a deep green precipitate

is produced by the sulphurates, which probably a hydrated sesquisulphuret.

Selenium and cerium form a powdery reddish-brown compound which has a disagreeable smell; when heated it yields selenious acid, and is converted into a white powdery subselenite. The sulphuret of selenium is not altered by water, but all acids dissolve it readily with the disengagement of seleniuretted hydrogen.

Phosphorus and cerium form by combining a powder, which, by exposure to heat and air, gradually becomes white, and is converted into phosphate.

Carbon and cerium, when united, form probably a quicarburet of cerium; it is black, interspersed with brilliant points, and weighs as much as the oxide of cerium employed in forming it. When exposed to the air it burns spontaneously, like a pyrophorus, and is converted into red oxide of cerium, and carbonic acid gas.

Salts of cerium.—Both the protoxide and sesquioxide of cerium form salts with acid. The protosalts are colourless, their taste is saccharine; they always turn litmus paper red; the greater number are soluble in water, and even in alcohol. They are not decomposed by sulphuretted hydrogen, but the sulphurets produce this effect. The ferrocyanide of potassium occasions a white milky precipitate, which is soluble in acids; the alkalis throw down a white precipitate, which is insoluble in an excess of them; tincture of galls produces no effect.

The salts of the sesquioxide of cerium are generally of a yellowish-red colour. When the solutions are concentrated, sulphate of potash is precipitated in the state of a yellow double sulphate.

Protobitrate of cerium does not readily crystallize; its taste is at first sharp, and afterwards very sweet. Its solution is colourless; water and alcohol both dissolve it in large quantity. When it is heated it first swells up, and is afterwards converted by heat into peroxide and nitrous acid.

Pernitrate of cerium.—The solution does not readily crystallize without an excess of acid; the crystals are white, lamellated, deliquescent, and soluble in alcohol. When dried, they become yellow. The solution decomposes spontaneously by keeping, and a yellow subsalt subsides, and an acidulous salt remains in solution. The admixture of a small quantity of nitrate of iron renders the solution of this salt blood red; it readily decomposes by heat.

Carbonate of cerium.—The protocarbonate is in white pearly scales; it is decomposed by heat, and by acids.

Protosulphate of cerium.—This salt may be obtained in colourless crystals, which are soluble in water, and require a high temperature to decompose them. The alkalis decompose this sulphate immediately, double sulphate being formed.

Sulphate of cerium is composed of

1 equivalent of protoxide	54
1 " acid	46

Equivalent to 94

Persulphate of cerium.—The solution of this salt is of an orange colour, and its crystals are prismatic, and of a golden hue. It is not a permanent salt, for it gradually becomes a mixture of super-protosulphate, and sub-persulphate. It is but imperfectly decomposed by the alkalis, forming, like the protosulphate, double salts with them.

Phosphate of cerium is a colourless insoluble substance, soluble in excess of acid, but dissolved in nitric and muriatic acids.

The principal minerals which contain cerium are considered as silicates—they are, cerite, orthite, gadcolomite, and allanite.

CERIUM, ORES OF.—1. *Cerite*, found near Riddarhitan, in Sweden; it occurs amorphous. Its colour is pale dull red, sometimes greyish, and its streak is white; its lustre is resinous, slightly translucent, and sufficiently hard to give sparks with steel, or 5-6. Sp. gr. 4.912.

According to Hisinger, it consists of

Silica	18
Peroxide of cerium	68.49
Peroxide of iron	2.00
Lime	2.25
Water and carbonic acid	10.25

99.44

Dr. Thomson considers it as a hydrous silicated of cerium.

2. *Cetine*, found as above, occurs massive and crystalline. Colour brownish-black, streak brown, opaque, with an imperfect metallic lustre. Har.

gr. 4. 173. Composition according to Berzelius.

Silica	39.7
Oxide of cerium	23.10
Iron	20.70
Copper	0.87
Alumina	11.7
Lime	9.12
Volatile matter	0.40

100.42

3. *Allanite*, found at Alluk, East Greenland. It occurs massive, and crystallized in the form of a doubly oblique prism. Fracture imperfect conchoidal. It is opaque, with an imperfect metallic lustre. Colour brownish-black, streak greenish grey. Hardness, 6.0. Sp. gr., 4. It is composed, according to Stromeyer, of

Silica	33.021
Protoxide of cerium	21.600
Iron	15.101
Manganese	0.404
Alumina	15.226
Lime	11.080
Water	3.000

99.432

These are among the principal ores of cerium, but for an account of some others, consult Phillips's *Mineralogy*, and Thomson's *Outlines of Geology*.

CERO'COMA, a genus of Coleopterous insects, of the family Cantharidæ (Latreille). Technical characters:—Antennæ short, nine-jointed, the basal joint as long as the two following, the second and next joints in succession are short and gradually increase in width to the apex of the antennæ; the terminal joint forms a distinct ovate knob; palpi moderate, all the joints of nearly equal width—such are the characters of the females. The males have the antennæ short, thick, and the joints extremely irregular in shape and size; those towards the base are uncommonly large, the terminal joint forms a large flattened knob, the joints immediately adjoining are the smallest—the palpi are also very much developed, the basal joints being very large. The head and thorax are rounded at the sides and of about equal width, the elytra are narrow, somewhat linear, elongate, and soft.

About six species of this genus (so remarkable for the extraordinary antennæ of the males) have been discovered, all of which are European; they make their appearance during the summer months, and frequently in great numbers in the same spot. They are found on flowers, particularly those of the wild chamomile, &c.

C. Schæfferi is about half an inch in length, and of a bright golden green above, or bluish; the legs and antennæ are yellow. In the female the base of the thighs and the tarsi are black. The colour of this species and the texture of its wings closely resembles that of the common blister beetle—the general form of the body is not very dissimilar; it is of a smaller size. This species is common in France.

CERO'PALES, a genus of Hymenopterous insects. [Pompilids.]

CEROXYLON ANDI'COLA, the wax-palm of South America, is one of the most remarkable plants in the large Mal order to which it belongs. It is a species with pinnated leaves, and panicled polygamous flowers. Its calyx consists of three small scales; the petals are also three, but much larger and sharp-pointed. The stamens are numerous, with very short filaments. The fruit is a little round rube, with a single seed of the same figure.

This plant has received from the American Spaniards the name of *Palma de Cera*, or wax-palm, on account of the abundance of that substance yielded by the stem. It grows, according to Bonpland, in that part of the Andes which separates the valley of the Magdalena from that of the Cauca river, in 4° 35' N. lat. Below the snow-capped mountains called Totima, San Juan, and Quindiu, especially the last, the *Ceroxylon* grows in all its grandeur, elevating its majestic trunk, coated with a thick incrustation of wax, to the height of 150 feet among the most rugged precipices of the wild region which it inhabits. Unlike the greater part of the palm tribe, this species avoids the heat of tropical

[*Ceroxylon Andicola*.]

plains, and seems incapable of existing except in regions where the temperature is lowered by elevation in the air, and the contiguity of perpetual snow. It is said to make its first appearance on the sides of the Quindiu at a height equal to that of the Puy de Dome or the passage of Mont Cenis; this is higher than the region of Cinchonas, and so cool, that Humboldt does not estimate the mean temperature of the year higher at the utmost than 65° or 68° Fahr., which is at least 17° lower than the mean temperature of palm countries. It does not extend over more than 15 or 20 leagues of country altogether. Its roots are fibrous and very numerous, the main root being thicker than the stem itself. The trunk is distinctly marked by rings caused by the fall of the leaves, which are from 18 to 20 feet long. The spaces between the rings are pale yellow, and smooth like the stems of a reed, and covered with a thick coating of wax and resin. This substance, melted with a third of tallow, makes excellent candles. Vauquelin ascertained that the vegetable matter consists of two-thirds resin, and one-third wax, which is only a little more brittle than bees-wax. The only parallel among palms to this property of exuding wax, occurs in a Brazilian palm with palmated leaves, called *Carnauba*.

CERTHIA. (Zoology.) [CREEPER.]

CERTHIA'DÆ. [CREEPER.]

CERTHILAU'DA. [LARKS.]

CERTIORARI, in law, is a writ issuing from one of the superior courts, directing the judges or officers of an inferior court to transmit or cause to be certified (*certiorari facias*) records or other proceedings. The object of the removal is either that the judgment of the inferior jurisdiction may be reviewed by the superior court, or that the decision and the proceedings leading to it may take place before the higher tribunal. An instance of the former is where the convictions of magistrates or the judgments or orders of courts of quarter-session are removed by certiorari into the Court of King's Bench by way of appeal against their validity, in which case the decision which has previously been given is re-considered, and is either confirmed or set aside. An instance of the latter is where an indictment found against a peer by an inferior jurisdiction is certified or transmitted into the Court of Parliament or the

Court of the Lord High Steward, in order that the proceedings and the adjudication may take place before proper tribunal. By this writ, indictments, and the proceedings thereon, may, at any time before actual trial, be removed from the assizes or quarter-sessions into the Court of King's Bench, as the supreme court of ordinary criminal jurisdiction. A *certiorari* for this purpose must be granted on the application of a prosecutor as a matter of right; but when applied for by a defendant, it is a matter of discretion, and is generally refused, unless under very peculiar circumstances. In order to avoid the occurrence of frivolous appeals, it is usual in statutes which give summary jurisdiction to inferior tribunals to restrict, or altogether take away, the right to a *certiorari*.

CERUSE. [LEAD, CARBONATE OF.]

CERVANTES. [SAAVEDRA.]

CERVICOBRANCHIATA. (Zoology.) De Blainville's second order of his sub-class *Paracephalophora Hermaprodita*.

Character of the order. Organs of respiration in a large cavity situated above the neck, and opening widely in front. Head distinct, with two conical contractile tentacula; eyes sessile at their external base.

Family 1. *Retifera*.

Organs of respiration in the form of a net on the *plafond* of the branchial cavity.

Genus *Patella*. (Limpet.)

Body more or less circular, conical above, flat below, and furnished with a large oval or round foot, which is thick and overpassed on the whole of its circumference by the edges of the mantle, which are more or less fringed. There is a complete series of vertical membranous plaits in the line of junction of the mantle with the foot.

[Animal of *Patella*.]

Shell oval or circular, with an upright summit, or more or less curved forwards. The cavity simple, and more or less deep: the border entire and horizontal. Muscular impression narrow, in the form of a horseshoe, opening forwards.

Such is De Blainville's arrangement and description; and, before we proceed further, it will be necessary to advert to Cuvier's remarks upon them. The latter places *Patella* under his Cyclobranchians (*Cyclobranches*, *Cyclobranchiata*), the eighth order of his (Cuvier's) Gastropods; and in the last edition of the 'Règne Animal' has the following note: 'M. de Blainville, who gives the name of *Cyclobranches* to the order under which he arranges the *Doridæ*, makes of the three preceding genera (*Fissurella*, *Emarginula* and *Parmophorus*) and of the *Patellæ*, an order which he names *Cervicobranches*, and which he divides into the *Rétifères* and the *Branchifères*. The *Rétifères* are the *Patellæ*, because he supposes that they respire by means of a net-work belonging to the cavity which is above their head. I have found it impossible to discover it; nor have I been able to see any other organ of respiration than the cordon of leaflets (*feuilleta*) which is carried all round under the border of the mantle.' And he refers to his anatomy of the *Patella* in his *Memoirs on the Mollusca*.

Cuvier thus describes the genus: 'The *Patellæ* have the body entirely covered by a shell made of one entire piece, shaped like a widened cone (*en cône évasé*). Under the edges of the mantle is a border (cordon) of small branchial leaflets (*feuilleta*). The vent and the outlet of the generative organs are a little to the right above the head, which is furnished with a large and short proboscis, and two pointed tentacula, carrying the eyes at their external bases. The mouth is fleshy, and contains a spiny tongue, which goes backwards and is folded back deeply in the interior of the body. The stomach is membranous, and the intestine is long, delicate, and very much folded. The heart is forwards, above the neck, a little to the right.'

G. B. Sowerby ('*Genera of Recent and Fossil Shells*'), says, 'There is no canal for the passage of water to the branchia, as there is in *Emarginula* and *Siphonaria*, for in this genus the branchia are external, surrounding the animal.'

We Cuvier, and his description of the animal differs but little from that given above. The terms not inaptly, un long ruban lingual épais, thus defines the genus. 'Animal furnished with eyes at their external bases, branchia forming a cordon of leaflets; shell univalve.' He afterwards gives a more detailed description of the shell, and makes the following observation: 'M. de Blainville believed that he has perceived the branchia of the *Patella* in a vascular network attached to the *plafond* of a branchial cavity. Not having been able to distinguish this net-work, we think with Cuvier that the organ of respiration shows itself in these animals in the circle of leaflets which surrounds the body between the foot and the mantle, as in the *Phyllidians*.'

Lamarck placed it among the *Phyllidians*, and next to *Chiton*, and gave a very good account of the organization of the animal; and Deshayes, in his valuable edition of the '*Animaux sans Vertèbres*,' adds to Lamarck's observations the following remarks: 'Till very lately naturalists had agreed upon the proper place of the *Patella* in the series of mollusks; to convince us of this fact, it will be sufficient if we cast our eyes on the different methods which have been published since the system of Linnæus. Nevertheless, a highly distinguished naturalist, M. de Blainville, in his '*Treatise on Malacology*,' has looked upon this genus with views different from those entertained by his predecessors. All naturalists had admitted without controversy, that the small leaflets placed in the groove of the foot and the mantle of the *Patellæ* were true branchia, comparable in all points to the branchia of the *Phyllidians* and *Chitons*. It was enough, in fact, to examine these leaflets with attention, to be satisfied as to their eminently vascular nature, and by a natural consequence to regard them as a respiratory organ in a situation which is common to other mollusks. M. de Blainville rejected this opinion, and perceiving in the part of the mantle which forms the cervical sac sufficiently regular striæ, he regarded this part as a true branchia or gill, and characterized the genus in consequence of this new opinion. By another consequence he changed the affinities of the genus, out of which he formed at the end of the hermaproditic mollusks, a small particular family under the name of *Retifera*, and composed of a single genus—that now before us. This new mode of viewing the subject by M. de Blainville demanded an attentive and serious examination previous to its adoption. Many methods present themselves for ascertaining if, as this zoologist believed, the cervical sac of the *Patellæ* serves them as a respiratory organ. We have compared with this part in the *Patella* that of many genera, the position of whose branchial organ has never been doubted—that of the *Calyptoræ*, for example; and we have recognized a fibrous structure and striæ entirely comparable to those which are seen in the *Patellæ*. We have pursued our comparison, not only in the mollusks with a patelliform shell, but further in those whose shell is more or less rolled up or spiral; and in all, without exception, we have found the upper wall of the cervical sac resembling that of the *Patella*. It must, then, be admitted, that in all the mollusks which have evidently a branchia, the cervical sac fulfils, as in the *Patella*, the functions of a respiratory organ; or, on the other hand, it must be allowed that if in all the mollusks the cervical sac does not serve for respiration, neither does it perform any function in the *Patella*.

'There is a curious genus named *Patelloida*, by MM. Quoy et Gaimard. In these mollusks the shell is absolutely like that of the *Patellæ*, and the animal has not only a cervical sac, but, moreover, a pectinated branchia on the right and anterior side of the body; and what is remarkable, it is deprived of those vascular leaflets disposed around the foot in the *Patella*. The abolition of these leaflets, as soon as a true pectinated branchia is developed, while the cervical sac undergoes no alteration, and remains the same in both genera, affords, by a rational induction, the strongest presumption for believing that the leaflets of the *Patella* are, in fact, respiratory organs. These two methods of induction of which we have spoken would themselves be sufficient to combat victoriously the opinion of M. de Blainville; but there is a third method still more preferable, that which anatomical investigation furnishes. When by

a minute dissection we have
 cial branches of the vessels, we find constantly, if
 thickness of the muscles of the lateral parts of the
 large vessels which reach along the whole circuit
 and branch a strong branch to each membranous le.
 This disposition is like that which is seen in the Chitons.
 The vessels which in the *Patella* are given off to the cer-
 vical sac are very small, and not to be compared with the
 development of those of the *Helices*, the *Limaces*, or even
 of the *Terebratulæ* and *Orbiculæ*, whose respiratory organ,
 though framed for breathing water only, is formed of a vas-
 cular net-work on a flattened membrane. In the *Patella*,
 the cervical vessels are not more developed than in the
 other mollusks, which, possessing a pectinated branchia,
 have also a cervical sac. It seems to us that we may con-
 clude from the preceding observations that, in the *Patella*,
 the cervical sac is not branchial, and that the branchiæ con-
 sist of the floating lamellæ between the borders of the foot
 and of the mantle. By a natural consequence then, it be-
 comes necessary to reject the opinion of M. de Blainville,
 and to place the *Patella* near the Chitons, forming a small
 family for each of these genera.

We have only to add, that recent observations leave no
 doubt, if any could have existed after the luminous remarks
 of Deshayes, that Cuvier and his followers were right and
 that M. de Blainville was wrong. The series of simple laminae
 attached within the circular border of the mantle fulfil the
 office of branchiæ, and to that end are endowed with cilia,
 which keep up a perpetual current of sea water over them.
 This current flows from the outer to the inner edge over the
 surface of each branchial lamina. The position of *Patella*,
 therefore, among the *Cyclobranchiæ* (eighth order of Gas-
 tropods), where it was placed by Cuvier before this charac-
 ter of the gills of gastropodous mollusks was known as it is
 now, ought not to be disturbed, and forms one, among many
 instances, of the penetrating character of Cuvier's mind.

The following is De Blainville's arrangement of the spe-
 cies; and, in the present state of our knowledge of the
 genus, is perhaps as good as any that has been proposed.

- α. Species whose summit is obtuse, vertical, very nearly
 mesial, and which are conical.—Example, *Patella*
vulgata. Locality, the coasts of European seas, common
 in the channel.—N. B. Varieties almost endless.

[*Patella vulgata*.]

- β. Species a little less conical, and whose summit is
 placed a little anterior to the position of the last, with
 a slight inclination forwards.—Example, *Patella*
deaurata. Locality, Straits of Magellans, Falkland Isles,
 &c.

[*Patella deaurata*.]

- γ. Species which are oval, elongated, and compressed at
 the sides.—Example, *Patella compressa*. Locality,
 Indian Seas, Lam.

[*Patella compressa*.]

* But see post, p. 442.

Species whose summit is sub-anterior and very little de-
 veloped, which are entirely flat or depressed.—Ex-
 ample, *Patella scutellaria*.

[*Patella scutellaria*.]

- δ. Depressed species, whose summit is scarcely indicated,
 and which are much narrower before than they are
 behind.—Example, *Patella cochlearia* (Cochlear).
 Genus, *Helcion*, De Montfort.

[*Patella cochlearia*.]

- ε. Oval species, with a well marked summit, evidently
 inclined forward and sub-marginal; border a little con-
 vex in the middle.—Example, *Patella pectinata*. Lo-
 cality, the Mediterranean sea.

[*Patella pectinata*.]

- ζ. Species which are oval, delicate, nacreous, and with a
 festooned border; the summit still more marginal and
 distinct.—Example, *Patella cymbularia*.

[*Patella cymbularia*.]

Geographical distribution.—The *Patella* are very widely
 spread, and few seas are without them. None however ap-
 pear to have been observed in the Arctic seas, either by
 Captain Parry (1819) or Captain Ross. The larger species
 are found principally in warm climates.

Habits, &c.—This genus is one of those which has the
 power of absorbing the shells of other mollusks or rocks,
 and thus forming cavities or depressions on them. The
*Patella cochlear**, says Mr. Gray, in his interesting paper
 on the economy of molluscous animals (*Phil. Trans.*, 1833),
 'is often found at the Cape of Good Hope, where it lives
 almost exclusively, attached to a large species of the same
 genus, on the surface of which it forms a flat disk, exactly
 the size of its mouth. To form these flat disks (of which

* Cochlearia.

there are so generally two, one on each side of the apex of the larger *Patella*, as almost to form a characteristic, and to assist in the increase of its size, the animal appears also to absorb the coralline or other similar substances with which the larger shells are abundantly covered. The common *Patella* of our own coast, when long adherent to another shell of its own species, to chalk, or to old red sandstone or limestone, also forms for itself a deep cavity of the same form as its shell, and evidently produced by the dissolution of the surface to which it is attached. These observations will strike every one who may take an interest in such subjects, and has opportunities of examination.

The species are numerous, and I think it highly probable that many of these will prove to be mere varieties when the subject comes to be deeply investigated. The following remarks on the subject by Mr. G. B. Sowerby and Mr. Gray will be read with interest, and we could add to them from our own observation: '*Patella*,' writes Mr. G. B. Sowerby (Genera of Shells), 'when detached from all the other genera which were associated with it under that name by Linnaean authors, forms still a genus very comprehensive in numbers; and though well characterised as a genus, the study of it is rendered extremely difficult, on account of the variations to which the species are liable from peculiarity of position or situation. This observation is suggested by the fact, that the *P. cerulea* is extremely regular and thin when it has lived upon the leaves and stems of sea-weed; and, on the contrary, irregular when attached to the rocks. We have also reason to believe that a like difference of situation is the cause of the great difference in character between *P. compressa* and *P. miniata*; but we are confident that they ought to be considered as varieties of the same, for we possess specimens in which, from the vertex to about half an inch from the margin, the characters are those of *P. compressa*, while the remainder of the same identical specimen is indisputably a well characterised *P. miniata*; it is remarkable that Lamarck should have observed the same fact, but considers it in some measure inexplicable.' Mr. Gray, in the memoir above quoted, thus contributes to this branch of the subject: 'When a *Patella* or a *Crepidula* has attached itself to the flat surface of a rock or the leaf of a large *fucus*, the base of its shell is flat and its mouth roundish; when it adheres to a concave surface, such as the cavity of an old shell, the base becomes flattened and convex internally; and when it fixes itself on the round stalk of a *fucus*, the sides become compressed so as in some measure to clasp the stem, and the lateral portions of the base project beyond the front and hinder parts to such an extent, that when placed on a flat surface it rocks backwards and forwards. Several nominal species of these and allied genera depend on variations in the shape of the shell, caused by the adhesion of the animal to surfaces of different forms; thus the *Patella pellucida* of Montagu is synonymous with the *P. cerulea* of the same author, the former having been founded on specimens taken from the stalk, and the latter on individuals obtained from the flattened frond of the *fucus*, on which the species usually takes up its abode: it is indeed by no means rare to find specimens in which the animal has moved from one of these positions to the other, and in such cases the shell represents *P. cerulea* and the base *P. pellucida*, or vice versa. The same change takes place with regard to *P. miniata* and *P. compressa*. I have in my collection a specimen of this latter shell, which is *P. miniata* at the top, it having in its youth lived on the frond of a large Cape *fucus*; it afterwards removed to the stem and became compressed, and consequently is in this part the *P. compressa*, but by some accident it was again induced to change its situation, and removing to a flat surface, the edge of the mouth expanded, and it became a second time *P. miniata*, or perhaps what may be called by some authors *P. saccharina*, as this also appears to be a typical variety of the same species. Lamarck has described a similar specimen; and Mr. Sowerby, in his Genera of Shells, has figured an example of this species, showing the two states. In like manner the *Crepidula forsteriana*, when applied to a flat surface, has an expanded base and a flattened inner lip; but when adherent to a convex body, such as the stem of a sea-weed, or (as frequently happens) to the back of another shell of the same species, the animal being pressed into the cavity, the inner lip becomes concave, and the sides of the aperture are contracted; in this state the shell is called by some

surfaces, they adapt their margins to the irregular which they meet. I have several specimens from of Devonshire, having one or more processes on their sides, which fitted into holes in the rock to which I found them attached; and such changes are the more remarkable, as some species are seen constantly moving from place to place, while others appear to remain for a long time fixed in one spot; and even those that are thus stationary in the young state constantly elevate the margins of their shells when the tide is low. I have also a specimen of *Siphonaria gigas*, exhibiting in a great degree a similar adaptation of its edges to the form of the rock on which it grew.

Patella has been found principally on rocky coasts, stones, and shells, at a depth ranging from the surface to thirty fathoms.

Food.—*Fuci* and other sea-weeds, in the separation and comminution of which their rasp-like tongues are probably highly active.

Before we proceed to the consideration of the fossil *Patella*, it may be expected that we should say a word of the allied genera, as far as shape of shell goes, *Siphonaria*, and *Patelloida*. These differ strongly in their organization from *Patella*, for instead of having a circle of branchial laminae like that genus, they have a single pectinated branchia on the right side. To these Mr. Gray adds the genus *Lottia*, which, as he (loc. cit.) observes, 'must be extremely perplexing to those systematicalists who attend only to the form of the shell without paying any regard to its animal inhabitant. The shells of *Patella* and *Lottia* do not in the least differ in external form, and yet their animals belong to very different orders, the one having the branchia placed round the foot, as in the chitons, and the other having them placed on the side of the neck, like the *Fissurellae*, from which indeed it chiefly differs in having only one branchia.' This description, by the way, accords with the genus *Patelloida* of Quoy and Gaimard. [PATELLOIDEA.]

The genus *Scutella*, brought home by Mr. Cuming from the Pacific Ocean, and described by Mr. Broderip in the 'Proceedings of the Zoological Society for 1834,' part 2, should here be mentioned. There is no doubt that the animal is marine; but unfortunately none of the soft parts were found, though the shells were in very fine condition; and, as we have seen, it is difficult in their absence to fix the precise place of the shell.

Generic Character.—Shell ancyliiform, shining within. Apex posterior, central, involute. Muscular impressions two, oblong-ovate, lateral. Aperture large, ovate.

This genus, according to Broderip, appears to be intermediate between *Ancylus* and *Patella*, while the aspect of the back sometimes reminds the observer of *Navicella* or *Crepidula*. Its place, he observes, will most probably be among the *Cyclobranchies* of Cuvier. The two muscular impressions are situated on each side of the interior, a little below the summit; while in *Patella* they nearly surround the internal circumference of the same part of the shell. The aperture is generally surrounded by a margin; and the apex, which in *Ancylus* is oblique, is central though posterior.

FOSSIL PATELLAE.

Deshayes, in his Tables, gives 104 living species and 10 fossil (tertiary); one fossil species, *Patella equalis*, now living in the European ocean, in the English crag (Pliocene period of Lyell), two at Dax and one at Valognes. G. Sowerby says that the fossil species are not numerous, and that they occur in the great oolite, in the lias, and perhaps in the Oxford clay and chalk marl of the secondary series; in the calcare grossier, and probably in the London clay of the tertiary series; and also in the crag of the diluvian formation. De la Bèche gives the following as being found among the organic remains in blue marls of the south of France: *Patella* *equalis* Lam.; *P. Bonardii*, Payrandeau (analogous to the living species), also in the calcare moellon; *P. umbella*, Lam. (also an analogue), and also in the calcare moellon; *P. glabra*, Deshayes, Paris. Among the organic remains of the cretaceous group he enumerates *P. apalta*, Nilis, from Balteberg, Scania; an undetermined species from the lower green sand of Sussex, Mantell, and another from the lower green sand of Wilts, Lonsdale. In the oolitic group he names *P. latissima*, Sow. Oxford clay, Yorks. and mid. and S. of England; *P. rugosa*, Sow. forest marble, mid. and S. of England

When the shells of this family are adherent to fragments

land; *P. lata*, Sow. Stonesfield slate; *P. ancyloides*, Sow. green dolite, Anellst. Wilts; *P. sama*, Sow. same locality; *P. discoidea*, Schlot. lias, Gundelsb. lias; and *P. papyracea*, Goldf. lias, Banz. The *genuwaake* group, according to the same author, affords *P. Neptuni*, Goldf. Eifel, O. *P. primigena*, Goldf. Pfaffrath; *P. conica*, Wahl. Kinn. lias, Westgothia; *P. pennicostis*, Wahl. Ulanda, Westgothia; *P. concentrica*, Wahl. Mosseberg, &c. Westgothia; and an undetermined species, Keswick, and near Kirby Lonsdale, Phil.

But the fossil zoologist will do well carefully to examine many of these so called species. Some of them are marked with a ? by the authors, and we have seen how liable to deception those who build upon the shape and structure of the shell alone are, even when examining the shells of recent species. The examples above given of mollusks with shells nearly identical, but of very different organization, should be borne in mind by the geologist, when he would draw conclusions as to the age, condition, or formation of a stratum, from the shells contained therein.

Family 2. *Branchiæra*.

Organs of respiration, two large equal pectinated branchiæ.

Genus, *Fissurella*.

The *Fissurella*, which Cuvier places among the *Scuti-branchiæ*, his seventh order of Gastropods, have a large fleshy disk or foot beneath the belly, like the *Patella*, and a conical shell fixed upon the middle of the back, but not always entirely covering it, for this shell is pierced at its summit with a small aperture, generally oval, which, according to Cuvier, serves at the same time as a passage for the water necessary to respiration and as an outlet for the excrements. This aperture penetrates into the cavity of the branchiæ situated on the fore part of the back, and in the bottom of which the vent discharges itself. This cavity is, besides, widely opened above the head. There is on each side, symmetrically disposed, a pectinated branchia or gill. The tentacula are conical, at the external bases of which the eyes are situated. The sides of the foot are fringed with filaments. Mr. Gray, in the memoir above quoted, says, 'In the young state of the *Fissurella*, the hole by which the faeces pass out of the shell is placed a little in front of its recurved and spiral apex: in this state it has been formed into a genus under the names of *Rhyncha* and *Puncturella*. But as the animal grows, the hole enlarges in size backwards, and the true apex being absorbed, the hole appears in the adult shell to be placed on the tip, and in some species even to extend behind it.'

The muscular impression is in the form of a horseshoe, with the opening in front.

[Animal of *Fissurella*.]

[Shell of *Fissurella*.]

De Blainville thus arranges the genus:

Species which have the middle part of the borders of the opening excavated, as it were, so that when placed upon a flat surface, they only touch it at their extremities.—Example, *Fissurella nimboza*.

[*Fissurella nimboza*.]

Deshayes observes that the synonymy of this species has been very faulty from the time of Linnaeus downwards; and he remarks that three species are confounded under *Patella nimboza* in the fifth edition of the *Systema Naturæ*. Deshayes adds that the species was named in Lamarek's collection, and that he has seen it, and therefore knows what Lamarek meant by his *Fissurella nimboza*. The figure from which our cut is taken, that of Martini, l. t. xi. f. 91-92, is one of those references which Deshayes would have untouched as indicating the species.

β. Species more depressed, &c., so that when placed upon a flat surface, the extremities are raised, forming a kind of canal.—Example, *Fissurella rosea*. Locality, Guiana, &c.

[*Fissurella rosea*.]

Conical species with horizontal borders.—Example, *Fissurella Græca*. Locality, Mediterranean and Atlantic.

[*Fissurella Græca*.]

Geographical Distribution, *Habits* &c.—Much the same as those of *Patella*. Like that genus *Fissurella* is littoral, and has been found at depths ranging from the surface to twenty-five fathoms.

FOSSIL FISSURELLÆ.

G. B. Sowerby says that a few fossil species are found in the truly marine formations above the chalk. Deshayes, in his Tables, enumerates 33 living species and 8 fossil (tertiary). Of these, *Fissurella Græca*, *costaria*, and *neglecta*, he states to be both living (the two former in the European and Indian oceans, and the latter in the Mediterranean) and fossil, in the pliocene (all three), and *neglecta* (the two latter) periods of Lyell, (Sicily, Italy in the sub-Apennine beds, English crag, and Touraine). He mentions three Sicilian species, three Italian (sub-Apennine beds), one in the English crag, two at Dax, two in Touraine, two at Angers, and four at Paris. The *Fissurella Nouchina* of Deshayes, *Patella Nouchina* of Lyell, is living in the Northern Seas, and found fossil in Sweden and Norway. It appears to be between a *Fissurella* and an *Emarginula*, and it is not impossible that it may be a *Fissurella* in a young state.

Genera, *Emarginula*.

Parmophorus.

Cuvier observes that the *Emarginula* have exactly the same structure as the *Fissurellæ*, with this exception, that the former, instead of the aperture at the apex of the shell, have in their mantle and shell a small slit or notch at their anterior border, which opens into the branchial cavity. The borders of the mantle envelop and cover a great portion of those of the shell.

The eyes are situated upon a tubercle at the external bases of the conical tentacula. The edges of the foot are

* Mr. G. B. Sowerby, in the Second Part of the Proceedings of the Zoological Society for 1834, describes 27 new species brought home by Mr. Cuming. Two others are also there recorded, making 29 additional species.

† The bracket that gives off these numbers includes *Emarginula*.

furnished with a row of filaments. G. B. Sowerby observes that the animal of the *Fissurella* is very nearly related to that of *Emarginula*, as the shell is to the *Emarginula* itself; the fissure in the anterior margin of the latter serving for the same purposes as the perforation in the vertex of the former. One difference however is regularly observed, which is that in *Emarginula* the vertex is directed posteriorly, contrariwise to that of *Fissurella*; for Lamarck is mistaken in speaking of the notch or fissure in the edge of *Emarginula* as posterior. Of *Parmophorus* Sowerby says that, like the *Emarginula*, its shell is covered

for a considerable portion by the turned-up edges of the mantle; this shell he describes as oblong, slightly conical, and without hole or notch. The *branchiae* and the rest of the organs are the same as they are in the two preceding genera. G. B. Sowerby thus writes upon this point (Genera of Shells):—'*Emarginula* is more nearly related to *Fissurella* than to *Patella*, inasmuch as its *branchiae* are not external, and the little fissure or notch in the anterior edge is only the termination of a narrow canal, that serves the same purpose in this shell as the perforation in the summit of *Fissurella*. It is observable that Lamarck has placed

Emarginula next to *Parmophorus*, without seeming to have remarked the very great resemblance of the animals to each other; we have thought ourselves justified, both by the characters of the shells and of the animals, in uniting them; this may be objected to perhaps on account of the great difference in general form; but we answer that there are some species of Lamarckian *Emarginula*, one of which we have figured, which approach very nearly to Blainville's *Parmophorus* in shape. Another objection may arise from the apparent want of the anterior fissure in *Parmophorus*, but it will be seen that the anterior edge of the shell is always somewhat emarginate, while in the situation of the *branchiae*, the anterior fissure in the mantle of the animal, and in the position of the vertex in the shell, they exactly resemble each other; we therefore consider the *Parmophori* of Blainville and Lamarck as elongated and compressed *Emarginulae*. Deshayes, in his edition of Lamarck (1836), thus expresses his opinion:—'Cuvier was the first who gave anatomical details of the genus *Emarginula*, and he made it appear how much analogy existed between it and *Fissurella*. There exists, nevertheless, between these two genera sufficient differences to warrant their continuance in systematic arrangement. But it is not so with regard to *Parmophorus*. M. de Blainville, to whom we owe this last genus, and who was the first to make the animal known, had judiciously preconceived the necessity of its junction with *Emarginula*. In fact, not only have the animals of the two genera a perfect analogy, and not only can they be with difficulty distinguished in some cases and in some species, but the shells themselves, as might have been supposed *a priori*, offer some passages from the one genus to the other, the number of which will be augmented by new researches. When we have before us a fairly complete series of living and fossil species belonging to the two genera, the following observations occur:—The two fossil species of *Parmophorus* have no trace of a marginal notch; *Parmophorus Australis* has the anterior border a little depressed in the middle, and within the shell is to be seen, corresponding with this depression, a small crest indicating the separation of the mantle. Among the species of *Emarginulae* brought home by MM. Quoy and Gaimard there is one which they name *Parmophoida*, and which would seem to be entirely deprived of a marginal notch. In the *Subemarginulae* of M. de Blainville, the shells have no longer this notch, but they have within a deep ridge (*stilan*) in the place of it. In other species, as in *Emarginula rubra* of Lamarck and *E. elegans* of M. DeFrance, the small interior ridge is terminated on the border by a very short notch, and from this commencement to the termination of the series of species we see this notch become deeper and deeper, and change at last into a deep slit, occupying one half of the height of the shell. After dwelling upon the differences of the shells in other points of structure and form, M. Deshayes observes that the general aspect of the shells leads the zoologist to separate the genera, while the structure of the animals tends to fuse them into one, and thus concludes:—'M. Sowerby has come, as we have before said, to the same conclusion, and in his "Genera of Shells" has united the *Parmophori* to the *Emarginulae*. This example will without doubt be followed

by the zoologists. We entirely agree in this conclusion, and consider the

following arrangement of De Blainville's *Emarginulae*, and calculated to assist the con- zoologist in his subdivision of this molla

Emarginula.

[Animal of *Emarginula*.]

[Shell of *Emarginula* (*E. conica*).]

- a. Species whose notch is in the middle of the back of the shell, and far from reaching the edge. (*Rimula*? or *Rimuloides*? of DeFrance).—Example, *Emarginula Blainvillii*.

[*Emarginula Blainvillii*.]

- β. Compressed species, whose anterior border is deeply notched, and the summit strongly marked (*Les Entailles*).—Example, *Emarginula Fissura*.

[*Emarginula Fissura*.]

- a, natural size; b, magnified; c, magnified, the shell turned up, showing the animal in situ.

- γ. Species still more compressed, whose anterior border is only bent into a gutter, and whose summit is still evident (*Subemarginulae*).—Example, *Emarginula Emarginata*.

[*Emarginula Emarginata*.]

- δ. Species very much depressed; the summit very little developed and præmedian, with a small notch.—Example, *Emarginula depressa*.

[*Emarginula depressa*.]

Parmophorus (*Scutum* of De Meuse).

Example, *Parmophorus Australis*; *Stenogastus*, *Patella ambigua*, Linn.; Localities, Seas of New Holland and New Zealand.

[*Parmophorus Australis*.]

Habits, &c.—*Emarginula* and *Parmophorus* are littoral shells like patella, and their habits are similar to those of the last-named genus. *Emarginula* has been found at depths ranging from the surface to eleven fathoms.

FOSSIL EMARGINULÆ AND PARMOPHORI.

G. B. Sowerby, 'Genera of Recent and Fossil Shells,' observes that the fossil *Emarginula* are scarce. 'They occur,' adds that author, 'in the calcaire grossier and its contemporary strata; in the crag of Suffolk, Essex, and Norfolk; and in the Bath oolite. They are very elegant little fossils, particularly Lamarek's *E. clypeata*. We cannot consider his *Parmophorus elongatus* as a species of this genus, for its vertex is anterior, as its muscular impression demonstrates; consequently we find in it no mark of a canal at either end; it must therefore be classed with *Patella*.'

Emarginula.—Deshayes, in his tables, gives seven living species and eleven fossil (tertiary), one *E. fissura*, an inhabitant of the European and Mediterranean Seas, fossil in the crag at Bordeaux and Dax, and at Paris (Pliocene, Miocene, and Eocene periods of Lyell). De la Bèche enumerates two in the blue marls of the South of France, namely, one closely approaching *E. fissura* of Lamarek and *E. reticulata* of Sowerby. In the cretaceous group he gives two, *E. Sanctæ Catharinæ* and *E. pelagica*, both from Rouen. In the oolitic group he records one species, *E. scularis*, Sowerby, from the great oolite at Ancliff, Wilts. Deshayes, in his edition of Lamarek (1836), enumerates eleven living species, and five found only in the fossil state, namely, *E. costata* and *E. clypeata*, Lamarek, from Grignon; *E. radiola*, Lamarek, from Parnes; and *E. elegans* and *E. clathrata*, Deshayes, the first from Paris and Valognes, and the other, a rare species, from Parnes.

Parmophorus.—Deshayes, in his tables, gives two living and two fossil species (tertiary), one from Touraine (Miocene period of Lyell); and he enumerates two from the Crag, three from Touraine, three from Angers, five from Paris, two from Valognes. In his edition of Lamarek, he notes two species only as fossil, one *P. elongatus*, Lamarek, with a variety, from Grignon, and the other *P. angustus*, Deshayes, from Paris.

CERVUS. [DEER.]

CESAROTTI, MELCHIORRE, born at Padua in May, 1730, studied in the seminary of that city, and showed from his early youth a great taste for learning, and especially for philological studies. In 1762 he was appointed preceptor of the children of the patrician Grimani at Venice, where he became acquainted with Mr. Sackville, who informed him of the appearance of Ossian's poems recently published by Macpherson. Cesarotti was so struck by their peculiarity and the novelty of the style, that he resolved on translating Ossian into Italian blank verse, which he effected with the assistance of Sackville. He dedicated his translation to the Earl of Bute, who caused an elegant edition of it to be printed at his own expense at Padua, 2 vols., 8vo., 1763, and made a present of it to the author. Without discussing the merit of these poems, it is but just to say that Cesarotti's translation is a fine specimen of Italian versification, being harmonious and fluent, and in many parts highly poetical. He broke through the tameness into which Italian poetry had sunk for more than a century before him, and gave the example of a new style and a bolder flight of imagination. Cesarotti however was not of a mind likely to be restrained within rational bounds. His bio-

grapher observes that, like the son of a miser, who is driven to the opposite extreme of prodigality, Cesarotti, born in a country that was stationary in learning, and at up among writers tame and timid in their investigations, seems to have determined on breaking through all the boundaries of language, taste, and composition, and attempting to effect a complete revolution in literature. His language is full of neologisms, and he had the hardihood to assert his preference of Ossian's poems to those of Homer. He attempted a version, or, as he called it, a reform of the Iliad, which he styled 'La Morte di Ettore,' in which he took such liberties with his text, that it may be considered as a parody rather than a translation. A caricature appeared at Rome, representing the head of Homer placed on the shoulders of a French dandy, with the legend 'Translation of Homer.' Cesarotti wrote some preliminary dissertations illustrative of the same poem, in which he displays much erudition and sounder criticism than in his version. His 'Saggio della Filosofia delle Lingue applicata alla Lingua Italiana,' Padua, 1785, is perhaps his best critical and philosophical work. He contends for the necessity of the written language keeping pace with the progress of ideas, inventions, discoveries, and new wants and habits. The academy of La Crusca was half inclined at one time to agree with the author, but veneration for purism and precedent prevailed among the members of that learned body. Count Galeani Napione wrote, chiefly in reply to Cesarotti, his work, 'Dell' Uso e dei Pregi della Lingua Italiana,' to which Cesarotti answered by his 'Rischiarimenti Apologetici sopra alcune Teorie Preliminari, o sul Francesismo.' The whole of this controversy may prove interesting to those who wish to form a clear idea of the disputes concerning language, which have formed a considerable portion of the Italian literature of our age. Cesarotti was appointed by the Venetian senate to the chair of Greek and Hebrew in the university of Padua. In his quality of secretary to the academy of Padua, he wrote, from 1730 till 1798, 'Relazioni Accademiche,' in which he gave at the end of every year an abstract of the memoirs read by the members of that body; and also 'Elogi di alcune Accademiche,' among which the most interesting is that of Abate Oliva, the author of the 'Zoologia Adriatica.' The 'Epistolario,' or voluminous correspondence of Cesarotti, was published in 6 vols., 8vo., Florence, 1811. In 1807 Cesarotti went to Milan, to deprecate the wrath of Napoleon against his countrymen of Padua, who had shown some disposition to resist the conqueror. Napoleon, who was a great admirer of Cesarotti's Ossian, received him in a very friendly manner, made him a knight of the iron crown, and bestowed a pension upon him. Cesarotti in return set about writing the praises of his patron in a poetical composition, which he styled 'Pronon,' the object of which is to show that Napoleon was the envoy of Providence. The composition is cold, full of allegories and metaphysical abstractions, and the style is turgid. The 'Pronon' was a still-born work, and its name is now only remembered among the many specimens of the flattery and servility of the Italian literary men in Napoleon's time.

Cesarotti died on November 4, 1808. His private character was simple and amiable; he was a man of regular habits, indefatigable in his studies, courteous to his visitors, friendly to those about him, and much beloved by his pupils. He translated several orations of Demosthenes, Isocrates, Eschines, Lysias, and other Greek writers, and also Juvenal. His essays and dissertations are numerous. His works were collected and published in 42 vols. 8vo., Pisa, 1809; the editors of the 'Classici Italiani' published a selection of them in 4 vols. 8vo., Milan, 1820.

CESSION. When an ecclesiastical person accepts a second benefice or dignity in the church, which is incompatible by law with that which he previously held, the latter is said to be void by cession. This avoidance takes place *ipso facto* upon the acceptance of the second benefice; and the patron may at once, without any sentence of deprivation in the spiritual court, and without any express resignation, present a new incumbent, and receive his admission. By the statute 21 Hen. VIII. c. 13, sect. 9, if a person, possessed of a benefice with cure of souls of the yearly value of 8*l.* or above, accept and take any other benefice with cure of souls, without a dispensation to hold both, the first is declared to be wholly void by law. But even if the first benefice be under the value of 8*l.*, and for that reason not within the statutory provision, it becomes void by the canon law as against the patron, in consequence of the acceptance by the

incumbent of a second benefice or dignity. (Watson's *Clergyman's Law*, cap. 2; Burn's *Ecclesiastical Law*, tit. Avoidance and lapses.)

GESTUM. [CITOGRADA.]

CETA/CEA. [WHALES.]

CETIC ACID, a substance obtained by Chevreul from spermaceti, and to which he has since given the name of *ethyl* [ETHAL].

CETINE is the name proposed by Chevreul for the crystallizable matter which forms the greater part of the substance called spermaceti. In order to obtain it pure, the spermaceti must be treated with boiling alcohol, and the clear solution, on cooling, deposits cetine, which, if requisite, is to be purified by a second solution in, and deposition from, alcohol.

Cetine is white, crystalline, soft to the touch, and friable; it is nearly inodorous, is tasteless, and does not act upon litmus: it fuses at 120° Fahr. When distilled in vacuo, it is volatilized without change; but when heated in a retort in the usual way, it yields a small quantity of acid and of oil, and a large proportion of solid crystalline product, traces of charcoal remaining in the retort. One hundred parts of boiling anhydrous alcohol dissolve 15.8 of cetine; but when its specific gravity is .834, only three parts are dissolved. If one part of cetine, an equal weight of hydrate of potash, and two parts of water are digested at a temperature between 122° and 194° Fahr. for several days, a soap is formed which is different from other soaps, containing margaric and oleic acids of potash, combined with an un-saponified fatty matter, which Chevreul calls *ethyl*. [ETHAL.] When this soap is decomposed by an acid, the ethal is separated with the margaric and oleic acids; 100 parts of cetine thus treated, give 60.96 parts of these acids, and 40.64 of ethal, the increase of weight amounting to 1.6. According to Chevreul, cetine consists of—

Carbon	81.660
Hydrogen	12.862
Oxygen	4.578

CETOCIS. De Montfort's generic name for those Belemnites which are plicated at the summits.

CETONIIDÆ (Mac Leay), a family of Coleopterous insects, of the section Melitophili (Latreille). The species belonging to this family have the sternum more or less prolonged into an obtuse point, between the second pair of legs; the mentum is emarginated, and never transverse; the terminal lobe of the maxillæ is furnished with a tuft of fine hairs; the labrum is concealed; the antennæ are small and ten-jointed; the basal joints are short; the three terminal joints are comparatively large, placed close together, and form a triphyllous knob. The thorax is generally somewhat triangular, with the anterior part (which would form the apex of the triangle) truncated. The elytra are usually rather straight at the sides, and obtusely rounded at the apex, thus presenting a somewhat square form; their disc is rather flat. A triangular scale is interposed between the base of the thorax and that of the elytra at their outer angles.

The Cetoniidæ form one of the most extensive groups of the beetle tribe, and nothing can exceed the brilliant colours with which many of them are adorned—in this respect vying with, if not surpassing, the Buprestidæ.

In the larva and imago states these insects feed upon vegetable substances: the grub or larva of the common rose-beetle very much resembles that of the cockchafer, and when about to assume the pupa state, encloses itself in a cocoon formed of particles of earth and rotten wood, or any surrounding substances, fastened together by means of a glutinous secretion.

In viewing a large collection of insects of this family, it is difficult to say what colours prevail most. In *Cetonia*, the typical genus of the group (in which the scutellum is of moderate size), the colours are generally burnished, and consist for the most part of various shades of green. *Cetonia Aurata* (the common rose-beetle) affords a good example of this genus; it is about three-quarters of an inch in length, and of a green colour, and sometimes copper-like colour, with two irregular fasciæ towards the latter part of the elytra, and extending from the side inwards: these fasciæ (and several little spots of the same colour which are observable on the elytra) are composed of a number of small scales, which, in old specimens, are often nearly all rubbed off. This species is known to require further de-

scription: it is seen very commonly in the south of England flying about in the sunshine during the months of May and June, frequently settling on roses, the leaves of which it greedily devours; it is also very fond of lilac and lilac flowers. If you chance the base of a tree that the insect will be found, this insect will be found licking it up, and collecting it by means of the tufts of hair with which the maxillæ are terminated.

Rösel informs us that he kept one of these insects alive for upwards of three years, during which time he fed it upon fruit and moist white bread.

Cetonia stictica, a small species, about half an inch in length, and of a black colour, with numerous white spots on the thorax and elytra, is said to have been taken at large in this country; its occurrence is however so rare, that it is doubted by some if it be truly indigenous. It is common in France and Germany, and is found on thistles.

C. fastuosa, a species which somewhat resembles the one first described, but is of a larger size, and without any spots, occurs in the south of France.

CETOPIRA. [CIRRHIPEDA.]

CETTE, a town and port of France, in the department of Hérault, on a narrow tongue of land, which separates the étang or pool of Thau from the Mediterranean, in 43° 24' N. lat. and 3° 42' E. long.

Cette is a modern town; its rise was connected with the construction of the Great Canal of Languedoc, of which its port forms one embouchure. The canal passes by a very winding course from the immediate neighbourhood of the river Aude, by Béziers and Agde, into the étang de Thau, from which a canal is cut through the narrow tongue of land above mentioned into the Mediterranean; and the port is formed by two moles or piers which extend into the sea on each side of the mouth of this canal. Before the construction of the canal of Languedoc there was a small hamlet (still existing in the neighbourhood of the town), which had about a score inhabitants, and which bore the name of Sette or Cetto, as did also a small promontory in the neighbourhood. The moles were completed in 1678, about two years before the completion of the canal of Languedoc; the principal mole runs E. & W. from the Cape of Cette, and has a battery and a lighthouse. The port is not very good, nor has it the natural facilities for becoming so; but its situation at the entrance of the canal, and on a coast which has very few harbours, keeps up the commercial importance of the place. It has canal communication by the Canal des Etangs, the étang de Mauguio, the Canal de Roubie, or de la Robine de Vic, with Aigues Mortes, St. Gilles, Beaucaire, and thus with the Rhône. In order to keep the sand from blocking up the port, the original moles have been lengthened; an insulated mole constructed across the mouth of the haven.

The town was originally on the west side of the canal, from the étang de Thau to the sea, but has since extended so as to occupy both sides; the older or western part is built on the side of the calcareous eminence which forms the headland of Cette; the eastern part is built upon piles: the two parts are united by a bridge. The town and port present a very picturesque appearance.

The population of Cette in 1832 was 10,638. The refining of sugar was established here in 1717, by some merchants of Montpellier, and is still one of the branches of the trade of the town. Snuff and soap are also manufactured, and the salt works of the étang de Thau employ many hands. Besides these occupations, the inhabitants carry on a great trade in the wines and brandies of Languedoc, of which this town is the dépôt, and they have considerable fisheries. The town is also frequented for its sea baths and sand baths. There are a marine school and a theatre.

Some writers contend that the name should be written Sette or even Sète. 'I conform to custom in writing Cette,' says M. Millin, 'but it seems to me preferable to write Sète. Festus Avienus names the mountain of Sète, *Sotius Mons*. Ptolemy and Strabo have both known this mountain; the first calls it *Ἐθριον ὄρος*, the second *Ἐθριον*. On the medal, referring to the construction of the port of Sète, we have these words for the inscription, "*Portus Sétius, 1666*." In the explanation of this medal (*Médailles de la France*, p. 91), the French name of the town is given in the same manner. *Voyage dans les Dép. de la France*. See also Malte Brun, *Géographie Universelle*.

CETUS, the sea-monster, called *Patrix* by Hyginus, and *Orphus* by some of the Greeks, is said to represent the mon-

star which is going to devour Andromeda. It is situated below Piazzi and Arjes, and a bright star in the head, called *Menkar* (α Ceti), comes on the meridian at eight o'clock in the beginning of January. It is usually drawn with a fish's head, two paws in front, and a curled fish's tail. The following is a list of stars—

CRULEN. [VAN CRULEN.]

CEUTA, a town and fortress belonging to the Spaniards on the north coast of the kingdom of Fez, in the empire of Morocco, and at the entrance of the Straits of Gibraltar on the Mediterranean side, where a small peninsula, about three miles in length, juts out in a N.N.E. direction exactly opposite Gibraltar. The peninsula is joined to the mainland of Africa by a narrow isthmus, on which the town is built, and is well fortified on the land side against any attacks of the Moors. To the N.E. of the town the peninsula spreads out in a rounded shape, and is almost entirely occupied by a mountain called Almina and also Monte del

Erroneously called υ¹ by Flamsteed.

Hacho, which forms part of the ancient Abyla, and from which there is a fine view of the straits, the plains and mountains of the interior, and the opposite coast of Spain. The main group of Abyla lies W. and outside of the peninsula of Ceuta, and forms a promontory called Capo Leona by the Mediterranean sailors. The mountain itself is called by the Moors Jebel Asatut, or Mountain of the Monkeys. There are some gardens irrigated by springs of water, where the vine, orange, lemon, and other fruit-trees thrive. Provisions for the inhabitants and the garrison are chiefly brought in by sea, for little communication is kept up between the inhabitants and the Moors of the interior. Ceuta has a small and not safe harbour, and 9200 inhabitants, according to Miñano, exclusive of the garrison. There is a cathedral, and a bishop suffragan of Seville. The military commander is also political governor of the place, and has under him the other presidios or forts held by the Spaniards on the coast of Morocco, namely, Peñon de Velez, Alhucema, and Melilla, the latter of which is about 150 miles E. of Ceuta towards the frontiers of Algiers. There is a house of correction for criminals sent from Spain, who are employed in the public works. State-prisoners are also sent here. During the late frequent political revolutions and reactions in Spain, many individuals of all classes have been confined in Ceuta for years by the prevailing party. Ceuta, or Septa, was a town of Mauritania Tingitana under the Romans. John I., king of Portugal, took it from the Moors in 1415. It came under the dominion of Spain in 1580, when Philip II. conquered Portugal. The Portuguese afterwards formally ceded it to Spain by the peace of Lisbon in 1668. In 1690 the Moors besieged it unsuccessfully. There is a good topographical drawing of the peninsula of Ceuta among the maps in the King's Library, British Museum.

CEUTORHYNCHUS, a genus of coleopterous insects, of the family Curculionidae (Leach). Technical characters:—antennae eleven-jointed, seven of which compose the funiculus; the basal joint is as long as the remainder taken together; the club is ovate. Rostrum sometimes long, bent, and filiform, and at others short and straight. Thorax with the fore-part much attenuated, with a channel beneath, in which the snout may be deposited. Scutellum minute and hardly apparent; the elytra are rounded at the extremity, and do not entirely cover the abdomen; the extremity of the tibiae is without spines.

The little insects of which this genus is composed are very numerous, and frequent plants of various sorts; some scarcely exceed a mustard seed in size. *C. didymus* is abundant on the common stinging nettle, and about the size of a hemp-seed. It is white beneath, and of a dull brownish black above; the sides of the thorax are white, and the elytra are furnished with two spots of the same colour; the apex of the elytra is also more or less white. When touched, or often when even approached, these little beetles close their snout in a groove on the under part of the body, contract the legs, and allow themselves to roll off the leaves to the ground, where they are with difficulty distinguished from the mould.

CEVADIC ACID, a peculiar acid obtained by Pelletier and Caventon from covadilla, the seed of the veratrum sabadilla. When this is digested in ether, a fat oil, consisting of stearine and elaine, is dissolved; this oil, separated from the ether by distillation, is then saponified by potash; this soap is decomposed by tartaric acid; the fat acids, set free, are separated by the filter; and the solution being distilled, covadic acid, mixed with much water, is condensed in the receiver: this is saturated with barytes, and the salt obtained by evaporation to dryness is mixed with phosphoric acid and distilled. The cevadic acid sublimes in white pearly needles which fuse at 67° Fahr., and exhale the same smell as butyric acid, or as rancid butter, which owes its smell to that acid. Cevadic acid sublimes at a few degrees above its melting point, and is soluble in water, alcohol, and ether. Its salts are but little known, but they retain the smell of the acid; ammonia precipitates the persalts of iron white.

CEVADILLA, SEBADILLA, or SABADILLA, is the Spanish-Mexican name for a species of Veratrum, the seeds of which have become an article of considerable importance, in consequence of their having been found to contain a considerable quantity of Veratrin. Much interest has been excited about this g. from the obscurity that is supposed to hang about its origin. It has always been understood to come from Botocú, who first referred the Cevadilla to Veratrum had no better mate-

rials to describe it from than a bit of the inflorescence which he found among a sample of the seeds. Smith, under *Veratrum* (in 1819), traced out its synonyms in Rees's Cyclopædia, but without throwing much light upon its history. Fée, in 1828, knew no more about it than what Retz had stated, adding that the meaning of the word was *little ear*, *Cebadilla* being a diminution of *Cebada*, the Spanish for oats. He considered it was fit for use as a horse medicine, and to destroy vermin. At a later period Descourtilz referred, in his *Flore des Alpes*, the *Veratrum Sabadilla* of Retz to a West Indian plant; and shortly after it was ascertained that there was also a Mexican *Cevadilla*, which corresponded entirely with the seeds of the shops. Thus again Mexico was fixed as the undoubted origin of that valuable production, in which the principle veratrina is found more concentrated than in any known plant. Dr. Schiede discovered it in grassy places near the Hacienda de la Laguna in Barranca de Tisoles, on the eastern declivity of the Mexican table-land, and it has been since described by Schlechtendahl and Chamisso, under the name of *Veratrum officinale*, in a paper of which the following is a translation. Root bulbous. Plant usually growing in tufts. Leaves linear, tapering to the point, even, quite smooth, entire, channelled on the upper side, keeled at the back, four feet long, rather weak. Scape naked, as high as a man, quite simple, terminated by a raceme a foot and a half long. Perianth deeply six-parted, spreading, yellowish, small, persistent, with thick blunt linear segments, of which three are rather broader than the others. Filaments six, somewhat club-shaped, yellowish, inserted into the base of the perianth, the three that are opposite to the broader segments rather longer than the others, and all longer than the perianth; anthers rather large, yellow, cordate at the base, obtuse; pollen yellow. Ovary superior, consisting of three carpels united by their sutures; styles very short. Fruit tri-capsular, the capsules adhering by their suture but readily separated. Lower flowers hermaphrodite and fertile, upper, male and sterile on account of the abortion of the ovary. Flowers have the smell of the common Barberry. This plant produces the true Mexican Sabadilla, or Cevadilla. But in the shops there appear to be seeds of two distinct species, one of which is the *V. Sabadilla*, the other the plant now described, which differs in having linear, keeled, channelled, and not ribgrass-like leaves, yellow and not purple flowers, segments of the perianth linear and shorter than the filaments, and not ovate or lanceolate, and longer than the filaments. Nearly related to this is a *V. frigidum*, found in the Alpine regions of Orizaba, where it flowers in September; this has blackish brown flowers, and is reckoned a poisonous plant by the Mexicans, who call it *Sevoeja*. It would be worth inquiring whether the *V. angustifolium* of Pursh, a plant occurring in the mountainous parts of Virginia and Carolina, and in the low lands of Ohio, Tennessee, and Louisiana, does not possess similar properties. We strongly suspect that all these supposed *Veratrum*s really belong rather to the genus *Helonias*, with the exception of *V. Sabadilla* itself, which seems to be a genuine species of the genus in which it stands.

CE'VÈNNES, a chain of mountains in the south of France, in Languedoc, forming the continuation of the mountains of the ci-devant provinces of Forez and Auvergne, from which they extend in a S.W. direction. They formerly gave name to the district of Languedoc, over which they spread; and in the acceptance of some writers this name has comprehended the districts of Gévaudan, Vivarais, and Vellai or Velai, though only a part of these districts is occupied by the Cévennes. These mountains are at present comprehended in the departments of Gard, Lozère, Haute (or Upper) Loire, and Ardèche. They may indeed be considered as extending into the departments of Hérault and Aveyron; for it is difficult to ascertain to what part of the chain to which they belong (which extends nearly to the Pyrenees, being separated from these only by the valley through which the canal of Languedoc runs) the name of Cévennes should be restricted. In this article we shall consider them as extending from the sources of the Orb, which waters Béziers, to Mount Mezen or Mezin, in the neighbourhood of the source of the Loire.

The general direction of the chain is N.E. and S.W. From Mount Lozère, which may be assumed as the centre of the chain, several branches are thrown off, as the mountains of Margeride towards Auvergne, serving to connect the Cévennes with the volcanic groups of that province; the ins of Aubrac, into the country watered by the

re and the Lot; and those of Levezou. Levezou, into that watered by the Aveyron. The Cévennes separate the streams which flow into the Mediterranean from those that flow into the ocean: the former (the Ardèche, the Baume, the Causse, the Cèze, the Gardon of Alais, the Gardon of Anduze, all of which flow immediately or otherwise into the Rhône; the Hérault, with its tributary the Ergue; and the Orb) rise on the S.E. slope of the chain: the latter (the Loire, the Lot, the Tarn, the Sorgues, &c., all of which, with the exception of the Loire, ultimately swell the current of the Garonne) rise to the N.W. slope. The highest points of the chain are La Lozère, 4888 feet; Gerbiac de Jones, in which the Loire rises, 5125 feet; and Mount Mezen, 5820.

In the absence of a trustworthy guide, we feel some difficulty in giving even an approximate statement of the dimensions of the chain. The following measurements are from the map of France, published at Paris, in 1818, by A. H. Brucé, and the map published by the Society for the Diffusion of Useful Knowledge: From Mount Mezen to Mount Lozère is 36 or 38 miles; from Mount Lozère the sources of the Orb, 56 or 58 miles. The breadth of the chain is more difficult to give, owing to its connexion on the N.W. side with the mountains of Auvergne: from Bedarriex to St. Rome on the Tarn is 34 miles; from Ganges on the Hérault to the Tarn between Ste. Enimie and Compeyre is 32 miles; from Aubenas to Pradelles, 28 miles. The country covered by the Cévennes may be roughly estimated at from 2500 to 3000 square miles. The S.E. side towards the basins of the Rhône and the Hérault has the most rapid descent.

The mountains L'Esperon, L'Aigoual, and others, near the source of the Hérault, consist of a variety of rocks, among which granite seems to predominate: the granite is of several varieties. Considerable detached blocks of this rock found lying on the surface are conjectured, from their rounded form, to be the remains of blocks, the angles and projections of which have been smoothed down by the action of the waters and the air. The mountain-streams of this district scarcely ever dry up in summer, and in their beds (especially of those whose waters have the greatest fall) are found masses of granite, rounded and polished by the action of the waters. These masses, some of which are from ten to thirty feet in diameter, appear to have been detached and brought down from a distance by the inundations caused by these streams; for the nature of the soil in the immediate neighbourhood of the spots where they are found precludes the supposition that they had their origin in the bed of the streams and have been denuded by the action of the waters. These rocks are surrounded with the debris caused by the destruction to which they have been subject. Some of the granite is so soft that its granular texture may be destroyed by the hand, or at any rate by the stroke of a hammer. The rocks of this part of the Cévennes, besides granite, consist of talcite and schistus: no marine shells are found in them.

The Cévennes contain several other species of granite. One species, not so common as that mentioned above, is of a dingy grey colour, inclining to yellow; it is found, not in blocks, but rather in veins of no great size; it is hard and close grained, cleaving sometimes across the direction of the vein, like slate, but into slabs of considerable thickness. This granite is used for building dry walls, as, from its cleavage being square, its surfaces admit of being exactly joined. There is another species, of a pinkish red colour, the hard varieties of which are similar in colour and hardness to Egyptian granite; but this is found only in one part of the mountains.

In other parts of the mountains the rocks are calcareous. The streams which flow from Mount L'Esperon, whether those which flow into the Tarn and by that into the Garonne, or those which flow into the Hérault, when they have their bed or their banks formed by calcareous rocks, are often absorbed, and re-appear after an interval varying from a quarter or half a mile to a mile and a half; and this notwithstanding their sources supply a sufficient quantity of water for them to flow on, under ordinary circumstances, without interruption. The place where a river is thus absorbed is called in the language of the country an *aven*. No similar phenomena are observed in the streams which have their bed in the granite district.

Wherever the granite predominates, the vegetable soil is very light and universally suited to the growth of certain

granite and sandy districts that the greatest size and height. Those vegetable soil is calcareous and the granite, being easily worn off by the heavy rains, form the sands, which being carried down to the Mediterranean by the Hérault and the Rhône, (many of whose tributaries rise in the Cévennes) serve to line with sand-banks the coast of that sea. It is in the granite districts that gold dust is found. Those who gain a livelihood by seeking it gather their most abundant harvest after the great inundations, when the waters have spread far over the neighbouring soil. It is only in granitic and talcose deposits that gold dust is found.

Talcite and schistus are found in the same district with granite, or with calcareous rocks; but the granite and the calcareous rocks appear to occupy different districts. Towards the base of the chain, considerable beds of roofing slates are found.

The Cévennes are naturally of difficult access; but the roads which were made by government about the close of the seventeenth or the commencement of the eighteenth century have done much to remedy this inconvenience. The country over which they spread contains, notwithstanding its rugged character, a considerable population. It furnishes an ample supply of game and fruit: chestnuts are particularly abundant, and constitute an important article of food to the inhabitants. The valleys, which are tolerably fertile, especially along the banks of the Rhône, furnish pasturage to a considerable quantity of cattle.

The cultivation of the sides of the Cévennes is carried on with great diligence, and places which would seem to be the least suited for it have been rendered available by the careful industry of the inhabitants. They raise across the ravines formed by the mountain torrents a wall of loose stones, through which the waters, when clear, pass readily; but after a storm or sudden shower, they bring down earth and stones, these walls act as a filter: the earth and stones are deposited, and in time form a platform of good ground. Successive platforms are raised one above another like a flight of steps. On these platforms vines and mulberry trees are planted, and potatoes, maize, and other species of grain are produced. In other places the natural terraces formed by the strata of the rocks which constitute the mass of the mountains are bounded by the walls of loose stones formed by the peasants, and the troughs thus formed are filled with vegetable soil obtained from the cliffs and cavities of the mountain, or conveyed by the peasants from the foot of it upon their backs. The disasters caused by the rains, which overthrow the walls and wash away or remove the soil, are repaired by the care of the hardy mountaineers, who, wrapped in an oil-skin dress, with a broad hat of tinned iron, bid defiance to the elements, and convert, by irrigation, to a useful purpose, the waters which would else destroy the fruit of all their labours; or they perseveringly repair the damage which they cannot prevent.

These mountains are mentioned by ancient authors, both Greek and Latin. Cæsar (*de Bel. Gal.* b. vii., c. 8) speaks of them under the name of Cevenna; * he crossed them in his contest with the Arverni and their confederates under Vercingetorix. The presumed difficulty of the passage had encouraged the Arverni, who deemed themselves covered from attack by these mountains as by a wall. The passage was made early in the year, and Cæsar had to make a road through snow six feet deep. Strabo gives to this range the name of *Κίμμερος ὄρος*, while Ptolemy uses the plural form, *τὰ Κίμμερα ὄρη*. The mountainousness of these mountains afforded refuge to the Huguenots in the religious wars of France. The inhabitants have retained till of late years the reputation of being a restless race, ever ready to revolt, and they have been ever suspected of being Huguenots in their hearts.

In 1703 the Huguenots of these mountains rose in arms and committed the most fearful excesses. They had been driven into rebellion by the persecutions to which they had been subjected on account of their faith and by fiscal oppression. The excitement was increased by the prophecies which were uttered by those who, either from mad enthusiasm or artifice, assumed the prophetic character. 'No taxes, and the land of conscience,' were the devices inscribed on their banners. With a fury naturally inspired by the cruelty and injustice which had goaded them into rebellion,

* Cevenna and Gebenna are various readings of this name in Cæsar. We follow Oberlin in giving Cevenna. Filmy and Mels give Gebenna.

they broke out into the most dreadful excesses. They sacked the churches and massacred the Catholic priests and laity, men, women, and children. The king was of sufficient importance to justify the employment of its suppression of the Maréchal de Villars, the most able, perhaps, of the French generals. 'Sire,' said Villars, in accepting the appointment, 'I will attempt, if your Majesty will allow to soften by mildness evils that rigour, in my opinion, only aggravate.' 'I leave it to you,' replied the king; 'you know well that I prefer the preservation of my people to their ruin, which I look upon as certain, if this unhappy war continues.' Villars immediately proceeded to the end of war; those who laid down their arms were leniently treated, those who continued to resist were destroyed. The submission of Cavalier, the leader of the Camisards, as these Protestants were called, a youth of extraordinary natural talents, though a heavy loss to the rebels, did not bring the contest to a close. Villars was called, to be employed in matters considered to be of greater importance; and it was not till 1705 that the revolt was put down by the duke of Berwick.

CEYLON lies between 5° 54' and 9° 50' N. lat., and 20° 50' and 82° 10' E. long. It is separated on the N.W. from the Continent of India by the Gulf of Manar. Its extreme length is about 270 miles from N. to S., and its extreme breadth 145 miles: the circuit is about 250 miles. Its area is about 24,664 square miles, or about 2000 square miles less than that of Ireland; but no accurate survey has been made. The population, according to the census of 1833, is 1,126,808.

In Sanscrit writings Ceylon is called Lanka, holy or resplendent; in the Singhalese annals it is called Sinhaladwipa, the island of lions. The Arabs named it Surenidib, which is only a corruption of the genuine name; and the Portuguese, Selan. It has been called Hebe-naro, the fertile island; Eclan, the insular kingdom; and Tenesserim, the place of delight. To the Greeks and Romans it was known under the name of Taprobane, and Salice (Ptolemy). Being favourably situated at the W. entrance of the Bay of Bengal, and bounded on the S. and E. by the Indian Ocean, it is admirably adapted for an entrepôt of eastern commerce: and though at present impoverished and thinly peopled, yet, through the impulse given to commerce and industry by the late abolition of pernicious monopolies and the emancipation of its people from compulsory labour, it promises to become one of the most important of the English possessions.

The eastern shore of the island is in many parts bold and rocky, and the water deep. The N.W. and W. shore from Point Pedro to Colombo is uniformly low, and indented with bays and inlets: the south and south-eastern shore is elevated, and presents a highly picturesque appearance.

The N.W. coast of Ceylon is almost joined to India by the island of Manar, Adam's Bridge, and the island of Ramisseram. There are only two passages through the strait. One of these, called the Manar Passage, which separates the island of Manar from the opposite coast of Ceylon, near Mantotte, is not above four feet deep at high water. The other, called the Paumban Passage, separates the island of Ramisseram, celebrated through India for its pagoda, from the opposite coast of India, near Tonitorré Point. This passage is very narrow, and not above six feet deep at high water.

An opinion which prevailed, that these passages were once much deeper, and might now be deepened without much difficulty, led to a particular survey of the Paumban Passage being made. But the result seems to be, that the passage has never been deeper than at present. The project of deepening the passage was abandoned in consequence of the refusal of the continental government to co-operate in effecting it, the expense being beyond the means of the Ceylonese government. But it is to be hoped, for the inter commerce, and more especially for the maritime trade of Ceylon and India, that it will yet be accomplished. Paumban is a narrow passage through a narrow ridge extending from the island of Ramisseram to the continent. The dam or ridge, which is 2260 yards long, runs E. and W., and is bounded by two parallel ridges 140 yards apart. The higher ridges the is in most places visible at low water, of the bottom only a few detached rocks appear in the space between the ridges is occupied with irregular masses of rock, having the is a soft sandstone, about three feet thick, resting on

of gravel; and it extends continuously in opposite directions on the island and on the continent. The ridge has the appearance of having been burst through by the sea; and the island Brahmins state that they were continuous in 1484 A.D., when the Swamp of Ramissaram was conveyed over them thrice yearly on particular festivals. A breach being afterwards effected, it was repaired, but it was reopened and enlarged by the violence of the waves, and it is universally believed by the neighbouring inhabitants to be continually enlarging. There are two passages in the dam: the eastern, used by vessels drawing not more than four or five feet water; and the western used by canoes and small boats only. The eastern passage is fifty yards broad, of irregular depth, and rocky bottom, winding and shallow; all which circumstances cause great delay and expense to vessels. In rough weather it is sometimes impassable, and frequently dangerous; and under favourable circumstances it takes three or four days to get through. In giving attention to the enlargement of the Paumban Passage, it is necessary to take into account a neighbouring sand-bank, on which there is only seven feet water, and which is probably a greater obstacle than the ridge of rocks: more especially as it is formed by deposits from the currents which run through the breaches in the ridge.

Adam's Bridge is the ridge of sand-banks connecting Manar with Ramissaram [ADAM'S BRIDGE].

The physical structure of the interior of Ceylon is not yet well known. The great mass of the high land is in the southern and wider part of the island, and the central parts of this mountain region seem to be intersected by the seventh parallel of N. lat. Numerous offsets from this nucleus are detached towards the S., S.E., and S.W. coast, forming the boundaries between valleys that are drained by rivers rising in the central mass, and running S., S.E., and S.W. This part of the island contains Adam's Peak, which was supposed to be the highest mountain in the island. But the most elevated point is now ascertained to be Pedrolallagalla, which is 8280 feet above the sea, and is surrounded by a tract of elevated country of very irregular surface, and well adapted for almost all the productions of temperate countries. This table-land is generally from 2000 to 3000 feet above the sea. From the central mass in the territory of Candy, a range of high land runs due N., probably nearly as far as 9° N. lat., forming the western boundary of the basin of the Mahawelli Ganga (the chief river of the island), and separating the waters which flow into this river, or towards the east coast, from those which run westward into the Gulf of Mappur. This range is very little known. The interior mountainous district contains numerous beautiful valleys, and prodigious forests. The N., N.E., and N.W. parts of the island are generally flat.

The island abounds with mountain streams throughout. The rivers are more numerous on the S. and

The gene, on the N.E. side. Those which flow through From Mount, on the E. and N. formerly filled the numerous of the chain, and rendered those districts the most fertile and rains of Marg, and these districts, now deserted of vines grown with them contain remains of numerous in computing and distributing the waters. The

l rivers are the Mahawelli Ganga (the largest of any), the Kalani Ganga, the Kalu Ganga, and the Walawe Ganga, all of which rise in the central mass. They are navigable only for boats and rafts. The Mahawelli Ganga, after descending from the high plains, and traversing the valley of Kotmale under the name of Kotmale Ganga, is joined, near Passage by a smaller branch from the base of Adam's Peak. It then passes through the village of Paradenya, four miles from Candy, where it is crossed by a modern bridge of one arch, 205 feet span, constructed of satin wood, on the American or wedge principle. Between Candy and Bintenne the river descends above 1000 feet, and receives in this part of its course numerous streams. At Bintenne, at the foot of the mountains, its average breadth is 340 feet, and its depth at the ford 5 feet; in the dry season 1 or 2 feet, and during freshes 25 or 30 feet. After a slow northern course through the country of Bintenne it separates into two branches: the smaller, the Vergel Ganga, enters the sea 25 miles S. from Trincomalee; the larger, retaining its original name, falls into the great bay of Trincomalee. It is ascertained that, by the removal of certain obstacles, which might be easily effected, the river might be made navigable as far at least as Kalinga, a distance of 80 miles. Its ancient navigation was interrupted by the turning of the stream. The Brahmins of the temple, at the mouth of the Vergel, in order to improve their lands, widened and deepened the Vergel at this point, by which the Mahawelli Ganga was made dry for ten miles from the point of separation for nearly the whole year. During the freshes there is however dangerous navigation for rafts round the elbow at the junction, where much timber is lost annually by the directors abandoning it, and swimming for their lives. As almost the only export from Trincomalee is timber, consisting chiefly of bal-maille, ebony, and satin wood, procured from the banks of this river and the vicinity, the importance of its navigation is obvious. This river flows through the country once the granary of the island, as indicated by the numerous remains of works of art for the irrigation of the land, which, now fallen into decay, serve only to form pestilential morasses. Its whole course is near 200 miles. The Kalani Ganga runs a west course for 35 miles to Ruwanwelle, and thence to Colombo. It is navigable, with little interruption in the dry season, for boats of considerable burden, higher than Talgammue. The Kalu Ganga takes a west direction, and after passing through the districts of Saffragam and Three Korles enters the sea at Cultura. It is navigable a little above Ratnapoora. The Walawe Ganga has a S.E. course to the sea, eight miles to the N. of Hambantotte.

Harbours.—At Trincomalee and Point de Galle there are harbours capable of containing the largest ships; and the roads of Colombo afford a secure anchorage at certain seasons: indeed, in the harbour of Trincomalee all the ships in the world might anchor, and be protected at any season. On the S.E. coast there are four ports in which small vessels may find shelter, and five on the N.W. coast.

Lakes.—There are a few lagunes in the island: those best known are in the vicinity of Negombo and Colombo. In the maritime provinces, at a very remote date, canals with stupendous embankments were constructed by the Singhalese to connect extensive salt-water lakes. Artificial lakes also were formed, many miles in circumference, for the purposes of irrigation.

Water Communication.—At present the only canal of any importance is that which connects Calpentyn with Colombo. It was projected by the Dutch, but long remained in an unfinished state, until Sir Edward Barnes, coming to the government, completed it about 1829.

The flatness of the districts bordering on the sea-coast has occasioned the formation of extensive salt-water lakes, or lagunes, which, by means of the channels connecting them, facilitate the intercourse of the maritime districts. Batticaloa, on the east side of the island, is much intersected by these lakes, which afford valuable means of internal communication. These lakes extend along the eastern coast to the northward of Trincomalee, partly separating the northern and southern parts of Jafna. This district, and that of Manner, lying between the coast of Coromandel, possess greater fertility than the coast of the continent than the districts to the southward, the native vessels being able to cross over at all seasons—a circumstance which favoured the Malabars in their invasions of

the country, and which now facilitates the commerce carried on with the continent.

The intercourse between Colombo and Galle and the continent is impeded during the S.W. monsoon by the boisterous navigation of the gulf of Manaar, and the dangers of the coast. This circumstance led to the formation of the canal which connects the lakes and rivers between Calpenny and Colombo. Calpenny is accessible to vessels during the S.W. monsoon; and their cargoes are conveyed thence in boats. This arrangement is of great commercial importance to the neighbourhood, and, with the advantages of climate and proximity to India, offers great inducements to settlers of all descriptions.

Roads.—The country being intersected by deep ravines, often impassable, and covered with thick jungle, the communications are rendered extremely difficult. Under the Canadian government the opening of roads was prohibited, and the passes were strictly guarded. Narrow paths were made, by which men on foot could pass singly, climbing over the rocks, and through the thickets. In thus providing for the defence of the country, its improvement was necessarily retarded; and from the little intercourse which subsisted with the maritime provinces, the habits and institutions of the people were of the most simple and primitive kind, exhibiting curious remains of their social condition in very remote ages. But since the occupation of the country by the British, and more particularly from the time of the administration of Sir Edward Barnes, who made great exertions to open the communications, which have been efficiently followed up by the present governor, Sir R. W. Horton, carriage roads have been constructed at a vast expense. That civilization receives a powerful impulse by the opening of communications, and that it advances in proportion to the facilities of commercial intercourse, are facts which have been well illustrated in Ceylon. Roads being opened they were covered with the vehicles of commerce. The fruits of the people's labours purchased those comforts and luxuries which had before been denied to their poverty; and in every respect they profit by intercourse with their more enlightened countrymen, and with Europeans. Bazaars and villages have sprung up along the roads; and the productions of Europe are sold in every village. Under the present governor a mail-coach has been established between Colombo and Candy, which already pays 8 per cent. to the proprietors.

The principal roads in the maritime provinces run along the sea-coast; and carriage-roads have been made from Colombo as far as Chilaw to the northward, and through Galle as far as Matara to the southward. Carriage-roads have also been made from Colombo to Candy; one by the way of Kurunegalle, which is in the direction towards Trincomalee, through the flat country; the other by a nearer route over a pass in the hills. Several other roads and communications through the districts have been opened, and some are now in progress. The main road to Candy, a work of great magnitude, has been carried through some difficult passes in the hills, and connected by several bridges,

the largest of which, over the Mahaweli, has been already described.

Climate.—The climate of Ceylon is principally influenced by the two monsoons. The north-east monsoon prevails from November to February, and the south-west monsoon from April to September. In the intervening months variable winds and calms prevail. The seasons are however subject to fluctuation; the north-west wind being generally more prevalent. Sometimes indeed at Colombo this wind blows for five months together, and the north-west wind blows during the months of December and January only. Local circumstances modify the winds of the interior according to the distance from the east and west coast; thus, at Battalia, in Upper Oovah, during the months of June, July, and August, the wind is variable, and for the remaining nine months it blows from the north-east. The heat is not so great as on the neighbouring coast of India, the sea-breezes moderating the temperature, and making the air more agreeable and salubrious. At Colombo the mean daily variation of the temperature does not exceed 3°, and the annual range of the thermometer is from 76° to 86½° Fahrenheit. At Galle the mean daily variation is 4°, and the annual range from 70° to 87°. At Jaffnapatam the mean daily variation is 5°, and the annual range from 70° to 90°. At Trincomalee the greatest daily variation is 17°, and the annual range from 74½° to 91½°. At Candy, 1457 feet above the sea, the mean daily variation is 6°, and the annual range from 66° to 86°; and at Newera Ellia, 6216 feet above the sea, the mean daily variation is 11°, and the annual range 33½° to 80½°; in 1831 however the highest temperature was only 73°, and this was attained but once.

In Colombo, in 1830, 102 inches of rain fell. Of these 102 inches, there fell in April, May, October, and November, in the following proportions: in April, 11 inches; in May, 21 inches; in October, 21 inches; and in November, 20 inches.

The eastern part of the island, which is open to the N.E. monsoon, partakes of the hot and dry climate of the coast of Coromandel. The western division, which is open to the S.W. monsoon, has a climate like that of the Malabar coast, which is temperate and humid. The N.E. winds, although accompanied with rain, are drier than those from the S.W., and the country over which they blow has an arid appearance, as contrasted with the luxuriant verdure of the southern and western districts, which continues during the greater part of the year. The driest seasons are those which are situated between the range of the two monsoons, partaking slightly of the influence of both.

The climate and seasons of the northern and southern districts may be thus strikingly contrasted. On one side of the island, and even on one side of a mountain, the rain may fall in torrents, while on the other the earth is parched and the herbage withered. The inhabitants in one place may be securing themselves from inundations, while in another they are carefully distributing the little water of former seasons, which is retained in their wells and tanks.

December	80	83	81	83	78	29.80	29.80	and N.E.	15.6	67½	73	71	76	63	No rain; dry; very cold nights.

* The rain gauge, showing a total of 85.5 inches, is at Candy (in 1819), in the interior, which shows the average of the island. On the sea-coast, at Colombo, the average annual fall of rain is from 76 to 80 inches. The station is situated on a plain surrounded by hills, from 1000 to 3000 feet high, in a mountainous country, in the southern extremity of Ceylon. The station is situated on the sea-coast, and is 1100 feet above the ocean level is 2107.

Very erroneous opinions have been entertained with respect to the insalubrity of Ceylon, founded on the returns of mortality among the troops while they were engaged in arduous service, and suffering from exposure, fatigue, and pestilential miasmatic influence; which, with our present better knowledge of the climate and localities, and the existence of the excellent roads which have since been constructed, would have been avoided. This is to be regretted, as it must doubtless have interfered most prejudicially to all parties in the business of life assurances.

The following is an abstract of the returns of mortality of the European troops at Ceylon, for several years previous to 1833 :—

97th Regiment, in a period of 7 years	2711	per cent.
78th " " "	6	" 2411/2 "
61st " " "	4	" 1631/2 "
58th " " "	4	" 11 "
Royal Artillery " "	4	" 203/4 "

The following is an abstract of the returns of mortality of the European troops in Ceylon for 1833 and 1834 :—

	No.	Deaths.	Per Cent.
1833 .. 1985 ..	57	21/2	
1834 .. 2060 ..	70	31/2	

From January to August, inclusive (eight months), as appears by an authentic return, the average number of sick in a regiment at Colombo was less than that of reserve companies of the same regiment stationed in Ireland, in the proportion of 10 to 16.

Europeans and the descendants of Europeans at Colombo sometimes attain the age of 100, without scarcely ever having suffered pain or sickness; and it is probable that were the island cleared and generally brought under cultivation, it would be as healthy as England. The climate of the maritime districts, especially those which are populous and therefore more generally cultivated, is more free from miasmata than those of the interior. By draining and clearing from jungle the neighbourhood of Trincomalee, its climate has been improved; while Seven Korles, a most productive province, has recently become unhealthy by the falling to ruin of tanks, and the consequent growth of jungle. Rank shrubs of luxuriant growth, found in marshy and uncultivated tracts, are most productive of miasmata. The low lands in the neighbourhood of Colombo, subject to frequent inundation, being regularly cultivated, do not affect the purity of the air; while an uncultivated marsh to the north of the town renders the winds which blow over it insalubrious.

Geology.—A few species of primitive rock in numerous varieties constitute the principal formations of the island. Granite and gneiss are the more prevalent; quartz, dolomite, hornblende, primitive green-stone, and a few others occur less frequently. The varieties of granite and gneiss, which often pass into each other, are very numerous. Regular granite is not common; but it is met with at Point-de-Galle. Gneiss is far more abundant than granite; a beautiful kind is found at Amanapoora ($7^{\circ} 15' N.$, $80^{\circ} 30' E.$), which contains a very large proportion of felspar. At Trincomalee quartz occurs in veins and in masses, embedded in granite. Hornblende and primitive green-stone are found on Adam's Peak. Dolomite is found only in the interior, and is used for making lime. It is in this rock that the nitre caves are found. The only recent rocks occur in the level belt near the sea. Fine-grained compact limestone is found in great abundance on the northern extremity of the island. Along the remainder of the coast sandstone generally prevails, lying in horizontal beds along the beach, but seldom extending beyond it.

Minerals.—Ceylon contains numerous useful minerals, and many valuable gems. Iron is very generally diffused. The black oxide of manganese is found. Plumbago abounds, and is exported in considerable quantities. There are no than twenty-two caves from which nitre, nitrate of lime, and a small proportion of alum are obtained. The sulphate of magnesia is found in only one cave, and according to Dr. Davy it is equal to the best Epsom salts. Salt is found in natural deposits, and is formed by artificial means in several parts of the maritime provinces, particularly in Mahagampatoo, and yields a revenue of 20,000*l.* per annum.

Of the gems of Ceylon the ruby and cat's-eye only are of high estimation; and among the late King of Kandy's jewels (sold by auction in London, in 1820), there was a large number of the latter stones, which measured two inches in diameter and sold for more than 400*l.*

There are several hot springs in the island: five at Trincomalee, and two in the province of Uva. The former are resorted to by invalids suffering from rheumatic and cutaneous disorders; at 7 A.M. the temperature of the air being 72° Fahrenheit, their heat varied from 86° to 107° . The water pure with the exception of the slightest trace of common salt and a little carbonic acid gas and azote. The Uva springs are more than 1000 feet above the sea, and have a temperature of 76° and 85° respectively. At Alotnoowera there are two springs, the temperature of which is sufficiently high to dress food. In lat. $7^{\circ} 15' N.$, lon. $81^{\circ} 20' E.$, near the Patapala river, there is a hot spring which constantly emits air bubbles.

Soil, Agriculture, &c.—Quartzose gravel or sand, and felspathic clay, mixed with oxide of iron, derived entirely from the decomposition of the prevailing rocks, generally compose the soil of Ceylon. The natural soils seldom contain more than three per cent. of vegetable matter, while quartz often constitutes nine-tenths of the whole. In the cinnamon gardens at Colombo the soil is composed of pure quartzose sand as white as snow. A brown loam formed by the decomposition of gneiss and granite, and a reddish loam resulting from the decomposition of clay iron-stone called *caboet*, are the most productive soils, and the quartzose the least so.

The line of coast from Negombo to Tangalle is particularly favourable to the growth of the cocoa-nut tree, which increases in value the nearer it approaches the southernmost parts of the island. Cinnamon is also chiefly confined to this district and the hills of the interior. The soils in the elevated lands of Saffragam and Lower Ouwah, and the granitic soils in the mountains above, are fertile. Coffee grows luxuriantly in the hilly country, and in Ceylon fine tobacco is produced. The provinces of Ouwah and Bintenne, to the eastward, and the adjacent parts of Saffragam and Tangalle, and the extensive plain to the north of the hills, are generally fertile, and were once populous and productive. They are now, except Tangalle, depopulated, though the remains of works for artificial irrigation are found there. The number and extent of works for artificial irrigation in the province of Nuwera-kalawa prove that it was once the most populous part of the island.

The soil of the northern division is sandy and calcareous, and is artificially irrigated and well tilled by the Mahabars. Near Jaffna is a natural reservoir, which the government attempted to appropriate for agricultural purposes. A steam-engine was applied to raise the water, but at a certain depth it was found to be brackish, and still deeper it was quite salt. In Jaffna rice and tobacco are most cultivated, but cotton and other plants thrive there. It is a good sheep country, and the Palmyra palm abounds. On the coast from Chilaw to Manaar and Jaffna on the western side, and from Tangalle to Mahagampatoo to the eastward, are the most valuable salt-farms.

The antient inhabitants appear to have been remarkable in the execution of works for the collection and distribution of water, the most remarkable of which are the spacious tanks excavated in the plains, and the dams constructed across the beds of rivers, or over ravines and valleys, connecting small hills, and forming extensive lakes for flooding the plains in the driest season. Such works are met with in the district of Tangalle, and in the deserted provinces to the northward and eastward, now the resort of the wild tribe of Veddas, who live chiefly by deer hunting. The lakes of Kandelay and Minery, each of which covers an area of several square miles, are situated in the plains extending from Trincomalee to Amanapoora, the antient capital of the island, and from thence across to Manaar and Arripoo, in which district a reservoir of great extent, called the Giant's Tank, was formed, and a stone dike was constructed across the Arripoo river to divert the current into it. These works are very antient, and of authentic records, to have been constructed three centuries before the Christian era. They were executed for the improvement of lands, and were probably distributed among the people employed in the work, who dedicated a portion of their revenues to the temples and priesthood.

The lands on the northern division are manured and cultivated with care by the Mahabars, who irrigate them extensively from tanks and wells. The arable lands and

divided into rice-fields, and enclosed by embankments to retain water. In the low countries, where they can be irrigated by rivers or tanks, extensive tracts are thus laid out. In the hills the rice-fields are cut in terraces, which are watered by the mountain springs, and separated by tracts of high ground attached to them, which are cultivated once in eight or ten years by cutting down and burning the jungle.

Lands were formerly assigned for the performance of certain services, or on condition of making certain contributions. The public land is now sold by auction at an upset price of 5s. per acre, a price not sufficient even to pay the expenses of surveying it, which is done by the government, and there is no tax imposed on the produce of lands so sold. Since the important change made in the tenure of lands, by relinquishing claims of service and substituting other relations in property, a remarkable impulse has been given to agriculture; waste lands are being brought into tillage, and more particularly in the high lands the jungle is being burned, cleared, and supplanted by the dry grains.

Vegetable Productions.—Among the trees indigenous to the island, cinnamon, of which Ceylon may be said to have the monopoly, is the principal; but the cocoa-nut tree is the most important to the island. This tree contributes largely to the subsistence of the people, and when the grain crops fail or are destroyed by inundation, averts much of the misery of so serious a calamity. The leaves of this tree, each twelve or thirteen feet long and three feet broad, together with the flowers, are used by the natives to ornament their dwellings on festive occasions. They are also an excellent food for elephants, and are plaited into *cadjans* and *cusingoes* for thatching houses. The leaves are also wrought into brooms, and *chools* or torches for travellers. The sap, called *toddy*, is extracted and used as a beverage in its natural state, and converted by distillation into arack. *Vinegar* is also made from this sap, and, by boiling, a coarse sugar called *jaggery* is formed from it. The kernel of the nut is used in culinary purposes; but the principal part is converted into *copperah* by being dried in the sun, and in this state is transferred to the oil-press. The oil is used for culinary purposes, for anointing the hair and body, for burning in lamps, and for making candles and soap. The refuse oilcake, called *ponnat*, furnishes good food for poultry and pigs. The shells of the nut are formed into gobbets, ladles, and other domestic utensils; and from the capsule cordage of all kinds, from the smallest yarn to a ship's cable, is manufactured. A great variety of other articles are manufactured from this tree; and the duties levied on the various products amount to 35,573l. per annum. In 1813 it was estimated that between Dondra Head and Calpentyne there grew ten millions of cocoa-nut trees, which produced, in addition to a great quantity of cocoa-nut oil, and six thousand leaguers of arack, upwards of three millions of pounds weight of coir. A good tree produced from 50 to 80, sometimes 100 cocoas in a year. Each cocoa-nut is considered equivalent, as to at least 3 oz. of rice.

The Palmyra palm is hardly inferior in importance to the cocoa-nut. It abounds in Jaffna, and being productive in seasons of drought, when the crops fail, is of great value to the people. The leaves are used in the construction of native huts, and also as a substitute for paper, and various other purposes. Toddy is extracted from it, as from the cocoa-nut tree. The timber is used for rafters, and is exported in large quantities. Punattoo is a jelly made from the fruit, on which the poorer classes subsist in seasons of dearth.

The *Albizia* tree is peculiar to the South: its sap produces a coarse sugar, and its fruit, dried and pulverized, serves as a substitute for rice flour.

The leaves of the talipot tree are so large that one will shelter many individuals. They are used by the natives to protect them from the sun and rain. When softened by boiling they serve to write upon; and are of great durability.

The Indian Areca nut is celebrated for its superior quality, and is exported in great quantities.

For cinnamon, see CINNAMON.

A great variety of timber abounds in the island, and the restrictions by which government formerly prevented its being cut without a licence have been removed. Calamander, satin, rose, sapan, iron, jack, halmalille, and other beautiful woods for cabinet-work are in profusion.

The coffee plant thrives, particularly in the interior, and has of late been greatly improved by culture. It has risen much in the estimation, as is shown by the market price, which is only exceeded by that of Mocha. The remunerating price of coffee in the island is 40s. per cwt., and the price in the London market is from 56s. to 62s. per cwt. The importation of coffee into the United Kingdom in 1832, the duty being 9d. per lb., was 2,824,998 lbs. The duty is reduced from 1st January, 1836, to 6d. per lb.; and the superior fertility of the soil, and the cheapness and abundance of labour considered, there is no doubt that the importations will be greatly increased.

Chaya root, which yields a scarlet dye, was once monopolized by the Government; but the monopoly has been relinquished. A particular class of natives only dig for these roots.

Tobacco is raised principally in the northern and southern districts. It has lately been exported only to Southern India, but the export duty having been reduced from 18s. to 2s. per cwt., it may be confidently expected that it will hereafter form an article of export to Europe, where it is approved, and to the Malayan markets as formerly.

Indigo grows wild, but is not now turned to account, though it was in ancient times exported from Trincomalee and celebrated all over India, Arabia, and Persia, and greatly enriched the Ceylon merchants.

The pepper vine grows almost in a wild state; the cardamom plant is abundant; fruits and culinary vegetables are produced in great variety and profusion.

Rice was once exported, in large quantities, from Trincomalee to all parts of India; but at present hardly enough is produced in the neighbouring provinces for the consumption of the small population. Maha Prakrama Bahoo, who reigned in the 12th century, is said to have turned his particular attention to agriculture, and to have constructed 1475 new tanks, repaired 1885 others; excavated 534 new canals, and repaired 3300 old ones. Judging from the remains of such works scattered over the island, the account is probably not exaggerated. These works might be restored and the lands again brought into cultivation. At present rice is imported into the island from the opposite coast. The value of rice imported in 1831, was 55,344l. A tax on the gross produce of the paddy, which varies from $\frac{1}{4}$ to $\frac{1}{2}$, but which may be generally rated, in the maritime districts, at $\frac{1}{4}$, is exacted by the government. The revenue from this source was, in 1828—20,523l.; in 1829—32,961l.; in 1830—35,057l.; and in 1831—35,548l.

In 1833, there were 456,206 acres in crop; and 1,674,136 acres uncultivated. The produce raised was—Paddy, 3,976,540; fine grains, 804,937; coffee, 88,378; pepper, 6273; mustard, 923; a kind of pulse given to horses, 26,947; maize, 34,477; peas, 24,278 bushels;—cotton, 1,336,547; tobacco, 3,624,684 lbs. The live stock on the island—horses, 1128; horned cattle, 591; sheep, 40,172; goats, 46,756.

Salt, arack, oil, and coir cordage are the principal manufactures. Iron, in small quantities, is smelted in the interior; and in the northern districts, cloths of moderately fine texture are made. A steam-engine is employed for expressing the oil at Colombo; and the more general introduction of this power is contemplated.

Animals.—The quadrupeds of Ceylon are for the most part like those of the opposite continent. Elephants are most numerous in the northern and eastern provinces; one European officer, in two years, killed four hundred. They often make predatory incursions in troops, and do great injury to the crops. Under the Candian government, the elephant was employed as a public executioner. After thrusting its tusks through the criminal's body, it tore him to pieces with its trunk, limb by limb. Elephants are generally found in herds. An elephant is sometimes excluded from the society of its fellows. Such elephant is always vicious and mischievous, attacking whatever approaches him, and passing herds will not permit him to join them. He is generally known and spoken of as the rogue elephant.

When the government commanded the services of the people, they were sometimes called forth in thousands to take the elephants in enclosures formed of strong stakes and trunks of trees. In the district of Putlam they were faced boldly in the open jungle, and ensnared singly for a reward varying according to the size and description of animal, from 11 to 352 rix.

There are several species of deer, of which the fallow deer are found in the greatest number; another of very diminutive size, called the *Cervus Aris*, which is caught by the natives, exposed for sale in the markets. Wild dogs abound in the plains to the eastward; and a small species of leopard is infrequently met with.

Of 24 different species of snakes examined by Dr. Davy, 16 were found harmless. The *Tic polle* is the most venomous, and is believed to lie in wait to attack passengers. Pea-fowl abound wild. *Biche de mer*, used for food and paste in China, is collected off Chilaw and Jaffna.

The chank (*voluta grovia*), abounds on the N.W. coast of Ceylon. There are two kinds, *payel* and *patty*, one red, and the other white. A third species, opening to the right, is very rare, and highly valued by Hindoos. The demand for chanks, caused by the rites of the Hindoo religion, was once so great that the right of fishing for them was sold by the government for 60,000 rix-dollars per annum; but the demand decreased until the revenue from this source became not worth collecting; and now this fishery is free to all. The chank fishery was important as a nursery for divers.

Pearl Fisheries.—The most productive pearl banks are situated off Condachy, extending 30 miles from N. to S., and 20 miles from E. to W. The fishery generally commences in March, when the calm weather permits the boats to go out and return daily. The average net revenue from pearls, for 32 years ending in 1832, was 14,662l. per annum. The net revenue realized in nine previous years was, in 1834, 145,000l. That realized in 1835 was, 38,000l.

Killecarré is most probably the Colchi mentioned in the Periplus of the Erythraean sea as the site of these fisheries; and they are carried on in the same manner as described by travellers several centuries ago. The ancient towns of Mantotte and Putlam probably derived much of their importance from their vicinity. The natural history of the pearl oyster is imperfectly known; but it dies soon after attaining its seventh year. In 1833, 1250 divers were employed, of whom 1100 were volunteers from the opposite coast. The share of profits gave each individual 5s. 9d. per day for the time he was employed: the price of ordinary labour being 6d. per day. But each bank being available only for one period, of about 20 days in every seven years, sometimes the fishery is smaller, and sometimes there is none at all; and in no season does it last for more than 30 or 35 days, commencing with the calm weather, about the 5th of March. The divers, in six or seven fathoms water, remain immersed from 50 to 55 seconds; very rarely longer. A reward being offered to him who should remain the longest under water, it was gained by one who remained 87 seconds. The diver's sack is not fastened round his neck, but is attached to a cord held by the man in the boat above; and it is pulled up when full, at the signal of the diver, who, if he choose, is drawn up with it. So far from the occupation being unhealthy, it is the belief of the natives that divers live longer than other labourers; and its short season is hailed as a gainful holiday by the divers themselves, who at other times are engaged in ordinary labour. If the oyster is taken before seven years old, its pearls are imperfectly developed; vigilance is therefore necessary to prevent indiscriminate fishing, which would destroy the banks, or at least render them quite unproductive. The pearls are sold by the government to the highest bidder. The sea fisheries are very productive on all parts of the coast.

History.—Onesicritus and Nearchus, commanders of the fleet dispatched by Alexander from the Indus to the Persian Gulf, brought the first accounts of the island to Europe.

Pliny states that Onesicritus had spoken of its elephants, and Megasthenes of its gold and pearls. Through a diplomatic mission which came to Rome from Ceylon in the time of Claudius, particulars were ascertained respecting its towns, population, and extensive trade, from which it appeared that the island was in a very prosperous and highly civilized state. Ptolemy speaks of rice, honey, and ginger, as the products of the island; and he mentions elephant feeding-grounds, the ancient capital, and various places, which from the similarity of their present names may be easily identified. Cosmas Indicopleustes relates, on the authority of his friend Smeronius, who visited Ceylon in the

and also proportion of Pagans who had been converted to Christianity. In the latter part of the 13th century the island was visited by Marco Polo, who describes it as the finest island in the world. About half a century later it was visited by St. John de Monteleville, who mentions Adam's Peak.

The Singhalese annals extant contain an uninterrupted historical record of events for 24 centuries, according to which their first king Hiyaya founded his kingdom by the extirpation of the original inhabitants about 543 B.C., and their last king, Shri Wikrama Raja Singha, was deposed by the British in 1798 A.D. Evidence of the authenticity and accuracy of these writings has lately given a new value to them. Many of their descriptions of towns and buildings, and other works of art, have been tested by an inspection of the now-existing ruins, and the evidence thence drawn has been confirmed by deciphered ancient inscriptions.

Of European nations the Portuguese first established a regular intercourse with Ceylon. The island being torn by internal wars, and invaded from Arabia and Malabar, the king purchased the assistance of the Portuguese with a stipulated annual tribute of 250,000 lbs. of cinnamon. The allies gradually gaining a footing in the island, at length, in 1520, strongly fortified themselves at Colombo, subjected the whole of the maritime districts, and retained possession of them for about 150 years. The Candians having called in the Dutch, the Portuguese were expelled, but the struggle lasted from 1632 to 1656. Batticaloa fell in 1636; Point de Galle in 1640; Negombo in 1644; and Colombo in 1656. The Dutch, like their predecessors, established their dominion over the maritime provinces, and, in 1761, having taken Candy, they would have subjected the whole island had not the sickness of their troops obliged them to withdraw from the interior. In the war with the French, in 1782, the British took possession of Trincomalee, but it was shortly after retaken by the French, and the sea-coast remained in the hands of the Dutch until 1796, when it was wrested from them by the British and formally ceded to them at the treaty of Amiens.

In 1815 the tyranny of the native king, who had forced the wife of his prime minister to pound to death her own children in a mortar, and other acts which rendered his dominion intolerable, led to his being deposed; upon which the British took possession of his dominions at the invitation of the Candian chiefs, and have retained them ever since.

Government, Law, &c.—The native government of Ceylon was strictly monarchical. The king was proprietor of the soil, regulator of the feudal payments and services, and distributor of all public honours and emoluments. The classification of the people and the distribution of lands being the basis of the system of government, the civil and judicial administration of the country was entrusted to chiefs placed over different departments and in various provinces and districts, with a gradation of inferior functionaries. The services of all were rewarded with certain privileges or possessions. The head men of each village, to whom the people immediately referred, directed the labour of the people under the authority of the provincial chief, and superintended the police. But the superintendence of agriculture was the duty of a particular class of persons who attended to the embankments of tanks and canals, and to the distribution of water.

The kings were found in possession of a monopoly of cinnamon and other valuable productions. The Portuguese, in 1597, permitted the people to trade in cinnamon on condition of their delivering one-fifth part of their collections to the government. This permission was withdrawn in 1626, and the Dutch, having disposed of the Portuguese in 1656, introduced a more rigorous system, requiring every other consideration to the securing of monopolies of the productions and the labour of the people. Private trade in all articles bringing a profitable return was prohibited, and the laborious services to which the natives were bound made them frequently abandon their lands, and the vigilance and severity were necessary to prevent the relaxing the tenures by which they were called to work gratuitously for three months in the year. The British soon after obtaining possession effected in Some branches of external trade were liberalized, as customs were abolished. Public functionaries were paid by salaries instead of lands, and claims on the services of the

people were commuted for assessed rents. Unfortunately for the country the expenses of the Ceylon war led to a reduction of a demand on their services, and now all men of certain estates, excepting the inhabitants of Colombo and its neighbourhood, without reference to their possessions, are compelled to labour in public services at rates fixed by government. In 1818, soon after obtaining admission over the Ceylon provinces, the commutation of gratuitous services for assessed rents, with a reservation to command the labour of the people at fixed rates of wages, was introduced there also. But the pernicious monopolies have at length been relinquished.

In September, 1832, the labourers of the soil hailed with delight the removal of their fetters, and set with spirit about their concerns. The Singhalese have availed themselves of the improvements which our matured knowledge and skill have introduced. The roads we have opened have been provided with the vehicles of commerce. The novel institution of a savings' bank they resort to with confidence; cultivation has spread rapidly: and, generally, there are the strongest indications of indefinitely progressive prosperity.

This prosperity is accelerated by an improving administration of the civil and judicial affairs of the country; and more especially by the admission of the natives to a participation in its administration. Various reforms have been effected in the revenue and expenditure, in the system of taxation, and regulations of commerce. And, above all, the moral character of the people has been raised by education, and by their being made eligible to the dignities and emoluments of rank and office.

The government is at present carried on by a governor and two councils—executive and legislative. The executive council consists of a president, who is the governor; and of the following members: the officer commanding the forces, the colonial secretary, the treasurer, the king's advocate, the government agent of the central provinces. The legislative council consists of a president, who is the governor; and of the following members: the chief justice, the commander of the forces, the colonial secretary, the treasurer, the auditor-general, the government agent for the western provinces, the government agent for the central provinces, the surveyor-general. With the latter council are now associated six unofficial members, natives or naturalized subjects of Ceylon, being chief landed proprietors, or principal merchants. The governor, the commander of the forces, the chief justice, the king's advocate, and the surveyor-general, are appointed by the secretary of state from England. The others are ex-officio members of the councils; and they are appointed by the governor, subject to the confirmation of the secretary of state. Until lately it was incumbent on the governor to select them exclusively from the civil service, but this exclusive principle has been relinquished. Printed copies of proposed ordinances are sent to the members ten days before summoning the council, and publicly shown in the government gazette to regulations or laws, one month previous to their enactment. The protests of opposing parties are entered on the minutes. The laws after enactment are subject to the approval of the king in council. The governor may not authorize contingent disbursements exceeding 75*l.* without the concurrence of his council. In his executive capacity the governor may act without referring to his council, but a record is kept of his proceedings, in the secretary's office, or in the department through which the measure is carried into effect. The regulations, translated into the vernacular languages, are made as public as possible.

With the exceptions above-mentioned, the principal official situation was filled by the civil servants alone, who were sent out by the secretary of state at an early age. Europeans, not of the civil service, and burghers engrossed the next inferior appointments, and Singhalese and Malabar natives were eligible only to a gradation of petty offices. The deficiency of better qualified Europeans led to the appointment of officers of the regiments in Ceylon to magistracies in the several districts, on small salaries in addition to their military pay, and they are found to conduct their duties with credit and efficiency. But an important change has been effected, and no person any individual whatever, possessing a competent knowledge of at least one of the native languages, and being otherwise duly qualified, may be appointed to the most

service, nation, or religion; subject however to the confirmation of the secretary of state. Though monopolies in the civil service are not to be feared up, there remain however about thirty-seven members of this corps who will continue subject for the most part to the regulations which affected them previous to the late change—and by their experience, talent, and qualifications, they will probably continue for a time to engross the higher offices.

The island is divided into five provinces, and each province is subdivided into districts. The provinces are denominated the Eastern, Western, Northern, Southern, and Central. In each province is stationed a government agent, and there are nineteen assistants to these agents, in various districts. These functionaries administer the affairs of government and officiate also as magistrates.

For the administration of justice throughout the island, there are, in the civil and criminal departments—a supreme court, established at Colombo; a vice-admiralty court, and provincial courts stationed in various districts; besides magistracies.

The powers of the supreme court are similar to those of the King's Bench and the High Court of Chancery combined. Justice is administered by three judges appointed from England. There is in this court—a king's advocate, with functions like those of the lord advocate of Scotland; a deputy king's advocate and registrar; and a proctor, who is a barrister, for pleading the causes of prisoners and paupers. By the generous and benevolent exertions of one of its former chief justices (Sir Alexander Johnston), trial by jury has been introduced. In 1811 it was enacted that every native tried before the supreme court for a criminal offence should be tried by a jury of his countrymen; and that the right of sitting on such juries should be extended to every native, whatever be his caste or religion. The beneficial effects of this measure have equalled the most sanguine expectations.

In each district there is a court held before a judge and three assessors; the judge is appointed by the crown and removable at pleasure. The assessors are selected from amongst the inhabitants, duly qualified, not under twenty-one years of age. The crown reserves the right of appointing one permanent assessor to each district court. The officers of the district courts are appointed by the governor on the recommendation of the judge. The supreme court is held at Colombo, except on circuit. The district courts are held within their own respective districts. The district courts have civil and criminal jurisdiction. They try all offences except those punishable with death, transportation, or banishment, imprisonment for more than one year, whipping exceeding 100 lashes, or a fine of 10*l.*

The judgments of these courts are pronounced in open court. The judge states in the hearing of the assessors the questions of law and fact, and the grounds of his opinion. The assessors declare in open court their respective opinions and votes. If the opinion of the judge differs from that of the majority of the assessors, sentence is given according to the opinion of the former, but a record is kept of the votes of the several assessors. Appeals may be made from these courts to the supreme court; but in criminal cases execution of the sentence is not stayed by the appeal unless the judge see fit.

The criminal jurisdiction of the supreme court extends throughout the island. The sessions of this court are held twice a-year, in each circuit, by one of the judges; and at the civil sessions, on circuit, three assessors are associated with the judge: the criminal sessions are held before the judge and a jury. In civil suits the judge and assessors deliver their opinions as in the district courts. Sentence of death pronounced at the criminal sessions by the supreme court is not executed until confirmed by the governor. Appeals are allowed to the king in council. The Dutch or Roman law, with certain exceptions, is administered in both the district and the supreme courts. All the witnesses in criminal cases are paid by government.

There are four regiments of European infantry, two companies of the royal foot artillery, and a regiment composed principally of Malays, a very fine and efficient body of men, nearly 2000 strong, of approved courage and fidelity.

The ecclesiastical establishment is composed of an archdeacon, six chaplains (of whom two are natives), and eleven

There is a vaccine establishment, under the superinten-

dence of the doctor- of hospital; and great efforts are made by the government to diffuse vaccination among the people.

A savings' bank has lately been established in Colombo, under the patronage of government. Deposits are not less than one shilling, and not exceeding five pounds in the whole, during each and every year, are received and invested, and interest at the rate of five per cent. per annum is allowed to the depositors. When the principal and interest together amount to 200*l.*, the interest given to the depositors on the amount is reduced to three per cent. The bank places out the money received in deposit at seven per cent. interest. Its prosperity is such, that it has already paid off a government loan of 2000*l.*, and has now a surplus after paying all its expenses.

At Colombo, a regular police has been organized, upon the model of the metropolitan police of London; and in its working and efficiency it has fulfilled the most sanguine anticipations. The police of the island generally is good, and crimes are speedily followed by detection, more especially in the Candian provinces, where the village police is excellent. But the Singhalese being a quiet, docile people, crimes are rare, and remarkably so in the Candian provinces. In some of the maritime districts, the drinking of arack leads to a great increase of crime. The coroners' inquests held in 1834, were on—deaths, by falls from trees, 49; by falling into wells, 25; by drowning, 41; by falls from houses, 2; by guns bursting, 1; by accidental shooting, 3; by other casualties, 5; killed by the bites of serpents, 20; by elephants, 13; by wild hogs, 4; suicides by hanging, 18; by drowning, 6; by the violence of others, 13; by drunkenness, 8; by natural sickness, 14; total, 222.

There are seventeen prisons, capable of containing in all 1763 prisoners. The numbers of prisoners lately, were— for debt, 69 male, 2 female; for misdemeanours, 230 male, 38 female; for felonies, 639 male, 16 female.

Education.—For the progress of education the island is principally indebted to religious societies, and the exertions of missionaries. Submitting cheerfully to privations the most severe, discouraged by no obstacles or unfavourable appearances, they persevere in their benevolent labours, while churches, schools, and printing-offices have sprung up around them.

The great desire of the natives to acquire the English language has led to a modification of the course of instruction. Instead of their knowledge being limited to a few translations in an imperfect language, other works of a more useful kind have been introduced. A very creditable work in the English language, a gazetteer of the island, has been published by a native, and numerous others have acquired an extensive acquaintance with the learning of Europe.

In the year 1833, there were 17 government schools, 5 regimental schools, 221 missionary schools, 766 private schools; of which 63 were under the Roman Catholic clergy; total, 1009.

The government school system, which had become very inefficient, is at present under total revision, and therefore nothing can be stated with certainty respecting it, or of the numbers educated.

The church mission, established in 1818, have four stations: Cotta, Gandy, Nellore, and Baddagamme. At the two last places they have seminaries, in which boys are boarded and educated gratuitously; and at Cotta there is a Christian institution where a select number of promising youths are qualified by a superior education to become assistant missionaries, or to fill other offices. In the schools of this mission are educated 1325 boys, 229 girls, 65 youths and adults; total, 1619.

The American mission commenced in 1816, and has at present seven stations in the Jaffna district. It has a seminary at Batticotta, containing 10 students in Christian theology; 84 in English and the elements of science; 20 pursuing the same branches through the medium of the native language; 8 day scholars; total, 129. It has also a central school at Oodooville for females. On the foundation, 51 girls are fed, clothed, and instructed. It has, in addition, other schools in eighteen parishes, containing 4241 boys, 821 girls; total, 5062.

The Wesleyan mission, South Ceylon district, established in 1814, educates 2044 boys, 451 girls; total, 3491.

The Baptist mission, instituted 1812, educates about 1000 children, of whom one-third are girls, in and about

Colombo, in the principles of Christianity. The particulars of Roman Catholic schools are not known.

Money.—The British currency is in circulation throughout the island, and accounts are becoming generally kept in the same. The rix-dollar is = to 1*s.* 6*d.*, or = to 12 fanams, (a copper coin = to 4 pice.)

Inhabitants.—The first colonization of Ceylon is involved in obscurity. If the original inhabitants differed from the Hindu race, they have been either extirpated or so amalgamated as to be no longer distinguishable from them. The population is at present composed of Singhalese, Malabars, Mohammedans or Moors, a small proportion of Europeans and their descendants, and negroes. The Singhalese inhabit the interior and the sea-coasts, extending from Kamakan aar, bounding Mahagampatoo, to the northern limit of Chilaw, and comprise the great body of the people. They are probably descended from the aborigines and the Gangetic nations, who invaded the island about 543 B.C. The language and customs of the Singhalese are in some respects peculiar. A woman was frequently married to all the brothers of the same family, but this practice is going out of fashion like many others. The civil distinctions of caste are strictly observed.

The abolition of the religious distinction of caste constitutes a remarkable peculiarity in the institution of the Buddhists.

The higher orders among the Singhalese belong exclusively to the caste of Gowiyo, and are distinguished by the epithet 'Handrow,' or gentleman. They are proud of long sounding titles and show, and the insulting distinction of superior and inferior castes is carried to a great length amongst them. Their occupations are purely agricultural; though the practice of agriculture is not confined to this class, but is exercised by persons of all castes. Different occupations are constantly followed by people of the same caste, but the intermarriage of persons of high and low castes is forbidden by the Candyan law, and many absurd distinctions are recognised and enforced, by which the latter are degraded and reduced to a servile condition, which becomes hereditary.

There is an exceedingly interesting class of natives, called Veddas, who inhabit the most secluded parts of the island, and derive their subsistence entirely from the natural productions of the soil and the forest, and from the chase. A cloth round the loins is the only clothing worn by them. Their habitations are, for the most part, small huts, constructed in the branches of trees, necessity having, doubtless, dictated the removal from a lower position, where their frail fabrics and their own lives must have been exposed to destruction by the herds of surrounding elephants.

The Singhalese are honest, sober, and polite, rendering a ready obedience to authority, and a pious attention to their relatives, particularly to those whose infirmities have made them helpless. They have been accused of being idle, deficient in courage and manly independence, and regardless of truth; but much of what has led to this accusation has resulted from the systems of religion and government under which their character has been formed.

The Malabars, or Tamuls, occupy the northern and north-eastern part of Ceylon, extending from Kamakan aar, bounding the Mahagampatoo, to the northern limit of Putlam, round by Jaffna. Their own traditions and the Singhalese annals inform us that they were invaders from the opposite coast, and formed a powerful kingdom in Jaffna, besides a number of petty states. The Malabars of Ceylon differ in nowise in personal appearance from those of the opposite coast, though in some points they differ from them in manners and customs. Those resident in Colombo are gradually taking up the manners and customs of the Europeans. Instead of sitting cross-legged on mats at meals, as formerly, they now sit on chairs or tables. Their meals are served up with regularity and neatness, and they no longer eat out of the same dish. Social parties, in the European style, are frequent, and lately, even balls have been given. The Malabars are Hindoos, and they have retained the religions, as well as the civil distinctions of caste, and the language and customs of southern India, under some modification, occasioned by their intercourse with the Singhalese; but they have not among them the tribe of Kahatriyas, though they recognize it in their classification.

The Mohammedans, or d from the re-

rious neighboring islands and the continent, with the converts they have made. They are found on all parts of the coast, as well as in the interior. These island settlers have become so much amalgamated with the natives, that they are not distinguishable from them in appearance or language. They even tolerate the distinctions of caste, and class themselves into four orders: merchants, weavers, fishermen, and bankers. They are a fine, energetic, and industrious race, who engross a large proportion of the commerce and traffic of the island.

The descendants of Europeans of unmixed blood, and that race which has sprung from the intercourse of Europeans with the natives, are called *Burghers*. From this class, almost exclusively, individuals have hitherto been selected for the clerkships in public offices, and for subordinate magistracies.

Religion.—Nicephorus supposes that St. Thomas, the apostle, preached the gospel in Ceylon; but modern writers agree in assigning to Nestorian missionaries, who accompanied the merchants from Persia, the introduction of Christianity into the island. From Cosmas Indicopleustes we learn that about the middle of the sixth century there were churches established here, but they no longer existed when the Portuguese arrived, and the permanent establishment of Christianity seems to have been effected by St. Francis Xavier, styled the apostle of the Indies. He preached in the neighbourhood of Manar in 1541, and 600 of his converts fell martyrs to the faith which they adopted. Roman Catholics are more numerous than Protestants. Of the Protestants, those of the Church of England are most numerous. There are some Presbyterians, Lutherans, Methodists, and Baptists. Buddhism prevails in the interior, and generally among the Singhalese of the sea-coasts. It is said to have been introduced about 306 years B.C. from Pataliputra by Dambadiva. Their priests are regularly educated for the sacred office, and at the close of their prescribed studies they are appointed to it with great pomp. In their priesthood they have orders corresponding to those of archbishop, bishop, priest, and deacon. Any of its members may divest himself of his priestly character, and re-assume it again. This is effected by relinquishing and re-assuming his distinguishing robe under certain forms. On putting off the robe he becomes a layman in all his social and political relations, and remains such until he again puts on the robe. In conformity with the treaty of 1815, the Buddhist religion is maintained and protected in the interior by the British government, which still selects and appoints the priests; and the exhibition of the Dalada relic of Buddha, at Candy in 1828, was conducted by the British governor in person. The temple patronage, and the possession of the Buddha relic, were important privileges of the kings of Candy, to which the British government succeeded. But this interference in the religious affairs of the country has been attended with much inconvenience: it has failed to satisfy the chiefs, and it has checked the improvement of the country and the advancement of the people.

In the northern parts the Hindoo religion prevails, but its professors are the followers of Siva.

Language.—The spoken language of the Singhalese is peculiar to themselves, but their classic and sacred writings are either in Pali or in Sanscrit. The Malabars use the Tamil, both for colloquial and literary purposes—excepting the Brahmins in Jaffna, who write Sanscrit in the *grantha* characters. The Ceylon Portuguese prevails in the European settlements, but its use is not universal among the natives. The Singhalese have among them, besides works on the life and doctrines of Buddha, many books in verse and prose common to eastern nations. They have also a history of the kings of Ceylon, in the first commencement of the Vajayan dynasty. The Malabars possess complete Tamil versions of various works of celebrity in the East, besides numerous original works on various subjects. Many works have lately been written by converts to Christianity in imitation of the literature of their rulers, which have reference to the scenes and events, of Europe, with which in their literature, as in other things, they seem anxious to identify themselves.

The natives have assiduously cultivated the Tamil.

Population.—The numerous remains of works of art scattered over the country demonstrate that the island was once much more populous than at present. Some districts, once flourishing, are entirely depopulated, and the population in all has greatly diminished, with the exception

Galle, Jaffna, and the maritime provinces the population is now increasing. It was in 1814 in 1833 338,611. Acc. in 1824 was, in the southern or Singhalese provinces, 399,408; in the northern or Candian districts, 195,697; and in the interior or Candian, 56,535: total, 832,940. In 1833 the total population amounted to 1,126,808, being 46 to the square mile; of whom there were employed in agriculture 354,459; in manufactures, 25,017; in commerce, 47,102. The births in 1833 were 21,654; the marriages, 8899; the deaths, 22,280—except for the following divisions, where no registers of births, &c. have been kept—Four Corles, Saffragam, Bintonne, Nuwerakulawa.

Commerce.—We have historical proof that, from the Christian era until the beginning of the 6th century, Ceylon was the emporium of the trade carried on between Africa, India, and China. The Romans particularly, after the discovery of the passage by way of Babelmandel to Guzerat, by Hippalus, until the decay of their empire, traded extensively with India and Ceylon; the latter place being the usual limit of their navigation, where they exchanged their gold and silver, the chief instruments of their commerce, for the silks, fine cloths, and costly commodities of Eastern India and China. This trade was afterwards engrossed by the Persians, the principal part of whose imports consisted of horses for the king. The persons on the island engaged in this trade were settlers—Arabs, Persians, Malabars, &c. The great commercial ports were Colombo and Galle, though grain and provisions were exported in abundance from Trincomalee to the opposite coast.

We are led back to the state of Ceylon before the Christian era by Pliny's quotations from Eratosthenes and other Greek geographers. The great source of their information seems to have been the mission of Megasthenes to Pali-bothra on the Ganges.

Pliny mentions the season favourable to the sailing of vessels at the Ceylonese ports to be during three months. Nearelius informs us that, on entering the Persian Gulf, he saw the promontory of Maketa (Muscat, or, more probably, Cape Mussendom), whence cinnamon and other things of the kind were conveyed to Babylon. We may infer that they were first taken to Muscat from Ceylon (Indic. 32).

In the 11th century the trade was entirely in the hands of Mohammedan Arabs, who circulated its productions through the Red Sea and Persian Gulf, and various countries of Asia, Europe, and Africa.

The vast commerce of Ceylon was not materially checked till the Portuguese engrossed the trade of its principal productions, and interrupted those maritime relations which had existed previous to the discovery of the passage round the Cape of Good Hope. But it was reserved for the Dutch system of pernicious monopoly to inflict vital injury on its commercial interests. The narrow policy or individual interest of the Dutch governors shackled the commerce of the island, and almost destroyed her natural powers of production. These impolitic restraints are being totally removed; though it may be still long before Ceylon will cease to feel the effects of the evils which she has suffered from misgovernment in her commercial affairs.

The value of exports in 1833 was estimated at 132,530*l.*; of imports at 320,891*l.* The quantities of some of the principal articles exported were, cinnamon, 77,530 bales. Oil, 112,671 gallons; coffee, 30,449 cwt.; coir-rope, 10,790 cwt.; arack, 3256 leaguers. The quantities of the principal articles of import were, rice, 775,593 parrahs; paddy, 438,617 parrahs; wheat, 34,879 parrahs; other grain, 10,108 parrahs. Cloth, in value, 81,194*l.* It may be mentioned here, that edible birds' nests, so much prized in China, have been found in Ceylon, and there is reason for inferring that they exist there in abundance, and will hereafter be exported to China.

The Dutch, in pursuance of their system, having acquired possession of the entire sea-coast, controuled the supply to the interior of salt and other commodities; and instituted customs and transit duties, which, together with the difficulty of transport, caused the inland trade to be very inconsiderable. Since the construction of roads, and the abolition of customs and transit duties by the British, the inland trade is rapidly increasing, and the markets of the interior are exposed for sale in every village. The Candian provinces consist principally of grain, coir, &c.

gery, and the principal source of salt is considered principally of salt.

The gross revenue of Ceylon has, for some years, averaged somewhat more than £330,000 per annum. But the abolition of the cinnamon monopoly, and other changes lately effected, render it impossible to estimate the probable net revenue. The revenue brought to account in 1834 was 292,554*l*.

Items of Revenue for 1833.

The revenue derived from land is collected in kind, and the grain is stored for the use of the troops and for sale. The importance of the cocoa-nut tree is shown by the superior revenue which it returns. In 1832, while the revenue derived from the tax on rice lands was about 21,300*l*., that derived from the cocoa-nut tree amounted to 35,772*l*., of which the following are the items:—Distilling of arrack 36,447*l*.; retail of do. 24,973*l*.; export of do. 31,367*l*.; do. of our rope 153*l*.; do. of jaggery 162*l*.; do. of copperahs 1539*l*.; do. of cocoa-nuts 1551*l*.; do. of cocoon-nut oil 413*l*.

The revenue on cinnamon is now collected on the export, instead of being a monopoly of the sale as formerly. The fish rents are raised by a duty of 10 per cent. on all fish caught. The revenue from the pearl fishery in the Gulf of Manaar is very precarious. The average annual amount for 32 years, ending in 1832, was 14,662*l*.. The net revenue from the same source paid into the treasury, during the nine previous years, had, in 1834, amounted to 145,000*l*.. The net profit realized by government, in 1835, was 38,000*l*.. In 1816 the Chank fishery produced 6700*l*.; its produce is now no longer worth taking into account. The gross revenue derived from salt is about 29,000*l*., but the cost of realizing it is 20 or 25 per cent.

The sea customs in 1833 amounted to 64,419*l*.; exports 132,530*l*.; imports 320,891*l*.. The progressive abolition of the export duties is an object of the present government, which they are rapidly carrying into effect, and a great improvement in agriculture and commerce will doubtless result.

For a long time after the British took possession of Ceylon, in consequence of internal wars and of the hostilities raging in Europe and on the continent of India, the revenue of the island was inadequate to meet the expenditure. But the revenue had of late years exceeded the expenditure until the year 1834, when the excess of expenditure amounted to 24,970*l*.. This excess was met by surplus funds in the colonial chest: and the returns for 1835, not yet received, must show a considerable surplus revenue, when swelled with 38,000*l*.. proceeds of the pearl fishery, and a considerable increase of cinnamon duty. The total expenditure for 1834 was 317,524*l*., of which about 32,958*l*.. was expended by the agent in England.

Since the late revision of government offices and re-arrangement, the scale of salaries of official functionaries in Ceylon is at least as economical as an enlarged and enlightened policy can admit. The practice of the Dutch was to remunerate their servants with salaries inadequate to place them above temptation in consequence of which they plundered the people to such an extent that, up to the present time, the island is suffering from the effects of this pernicious system of administration.

* Since abolished.

CEYX. (Zoology.) [KINGFISHERS.]

CHABLAIS, a province of Savoy in the Sardinian States. It extends along the S. coast of the lake of Geneva, and inland as far as an offset of the Alps, which detaches itself from the lofty mountain called La Dent du Midi, on the borders of the Valais, and running in a W. direction divides the sources of the river Dranse, which flows N. into the lake, from the waters of the Giffre, an affluent of the Arve, which flows W. into the Rhone below Geneva. The Chablais is bounded on the S. by the province of Faucigny, of which the valley of the Giffre forms part; on the W. by the Canton of Geneva, and on the E. by the Valais. The length of Chablais from St. Gingouph, on the borders of the Valais, to Hermance, on those of Geneva, is 27 miles, but the distance is considerably greater by the road, which follows the curve made by the shore of the lake. This road is part of the great Simplon road made by order of Napoleon. The greatest breadth of the province, N. to S., from Evian to the sources of the Dranse is about 21 miles. The area, according to Neigebaur, is 377 square miles, and the population in 1824 was 48,919 (*Calendario Generale dei Regi Stati*). It is a very mountainous country, with the exception of a strip of land along the shore of the lake of Geneva, which produces corn, wine, and fruit, but its N. aspect renders it less favourable to production than the opposite coast of the Canton de Vaud. Several narrow valleys run inland between the offsets of the Alps, along the course of the Dranse and of its affluent. These valleys abound in rich pastures, on which large herds of cattle are fed. Very good cheese is made in part of the country, both for consumption and exportation. The country abounds also with chestnut and walnut trees. The principal towns of the Chablais are the following:—1. Thonon, built on an eminence above the lake, in the midst of a fine and well-wooded country, is the residence of the intendant, or governor of the province, has a Tribunale di Prefettura, or court of justice, subject to appeal to the senate at Chambéry, a royal college, and a convitto for student boarders, several churches, convents, a handsome town-house, an old castle, and about 1000 inhabitants. At Ripaille, near Thonon, is the once rich and handsome convent founded by Amadeus VIII., afterwards Pope Felix V. The building and grounds, including a handsome park, were sold by auction under the French. The building has been sadly dilapidated, and the church, rich in marbles and stuccoes, was for a time used as a hayrack. The present occupiers have made a villa of it, and added by rustic dwellings for the labourers. (Bertolani, *Atlas de Savoie*, 1828.) 2. Evian, a small town, situated on the coast of the lake, nearly opposite Lausanne, in Switzerland, has about 1800 inhabitants. Between Thonon and Evian, on the right bank of the Dranse, are the mineral waters of Amphion, which were much frequented in the 18th century by visitors from Geneva. Inland, among the Alps, is the village of Abondance with 1400 inhabitants, in the valley of the same name, so called for the richness of its pastures.

Its abbey, founded by St. Columbanus in the beginning of the sixth century, as well as another abbey of Bernardines at St. Jean d'Aulps, in a neighbouring valley, are now expressed. On the east of the lake towards the borders of Valais, was a town called Tauretum, which was destroyed by the fall of the mountain, A.D. 563. The rocks of Meilleri celebrated for the manufacture of glass, are in this neighbourhood. The highest summits in the Chablais are, the Dent d'Oche, the borders of the Valais, 7000 feet above the sea; the Col de Jouxplane, a corruption of Jovis planities, or the plain of Jupiter, which rises between the Chablais and Faucigny above the valley of the Giffre, and is about 1000 feet higher than the Dent d'Oche; and the Roc d'Enfer, which rises above the valley of the Dranse, near the centre of the province, and is about the same height as the latter. (Keller's Map of Switzerland.)

CHABLIS. [YONNE, DEPARTMENT OF.]

CHABRIAS, a distinguished Athenian general, who, in B.C. 388, sailed to Cyprus to assist Evagoras in the reduction of the island (Xen. *Hell.* iv., 8. 24), of which his father had been deprived by the Persians. In B.C. 376 he gained the sea-battle at Naxos. (Demosth. *Aristocrat.*, p. 686; *Chetop.*, *Fast. Hell.*) In 373 he and Callistratus acted as envoys of Iphicrates at Coragra. (Xen. *Hell.* vi., 2. 39.) He was despatched to settle the affairs of Thrace in 360 (Demosth. *Aristocrat.*, p. 677.) In 357 Chabrias and Chares were sent from Athens with an army to besiege Chios, which, with Rhodes, Cos, and Byzantium, had revolted. (Diodor. Sic. xvi., 7.) Chares led the land forces and attacked the walls from shore. Chabrias no sooner approached the harbour than he engaged in a desperate sea-fight; his ship was shattered by the enemy; most of his men escaped, but the general himself preferring, as Diodorus says, a glorious death to a disgraceful surrender, fell fighting. (Diod. Sic. xvi., 7; *Görn. Nep.*, c. 4.)

CHIRONIA, an old city of Boeotia, on the borders of Phocia, near the pass which led to Delphi by Panopeus and Parnassus (Thucyd. iv. 72); it was twenty stadia from Panopeus (Pausan. x. 4). The name of this place does not appear in Homer's catalogue; Pausanias, however, conjectures (ix. 40. 3) that it is a later name for Arne, which stood on the same ground. It is principally celebrated for two battles fought here; one in which Philip of Macedon signally defeated the united forces of Athens and Thebes; the other between Sulla and Mithridates, in which the Romans gained a decisive victory. During the Peloponnesian war it was tributary to Orchomenus (Thucyd. iv. 76); but in later times it was one of the confederate Boeotian towns (Pausan. ix. 3. 4). Its situation was the cause of much good and evil to it; on the one hand its neighbourhood to the pass exposed it occasionally to plunder (Thucyd. i. 113); while on the other hand, as the main road from Rome to Athens passed through it, many of the advantages of the carrying-trade accrued to it. Pausanias tells us (ix. 41) that its inhabitants derived a great profit from the cultivation of the olive, and the manufacture of perfumes from flowers. The site is now occupied by the town of Caperna (Walp. *Mem.*, p. 342) or Capurno (Dodd. i. p. 224), where there are remains of a theatre and other buildings. According to Gell's *Library* (p. 222), the town lies about an hour's ride south of the Cephus. It was the birth-place of Plutarch.

CHÆTODON (Linnaeus), a genus of fishes of the section Acanthopterygii and family Squammipennes. Technical characters: body compressed; mouth small, furnished with several rows of long slender bristle-like teeth. The scales (which are usually confined to the body) in this genus extend on to the dorsal and anal fins, so that it is difficult to see where the latter commence.

These fishes abound in the seas of hot climates, frequent rocky shores, and are adorned with beautiful colours. Their most common tints appear to be black and yellow, but brilliant metallic blues and greens, of various hues, are not unfrequently seen. Many of the species have a vertical black band in which the eye is placed. In some there are several similar vertical bands on the body; in others the body is spotted, or adorned with oblique or longitudinal bands. They have a large head; their intestines are long and ample, and their scales are numerous, long, and slender. Their flesh is good eating.

The species are numerous and have been divided into several groups, which have been derived from the nature of their teeth, being derived from the (genitive) *Chætodon*, and the (genitive) *Chætodon*.

several subgeni. Those to which the name *Chætodon* is now restricted have the body more or less compressed, the rays of the dorsal fin forming a tolerably uniform fin, the snout more or less produced, and the preoperculum sometimes furnished with a small tooth.

In some species, one or more of the soft rays of the dorsal fin are much produced and form a long filament, and these are distinguished by their having very few spines to the same fin.

Chætodon vagabundus, a species which inhabits the coasts

[*Chætodon vagabundus*]

of Ceylon, has the body of a pale yellow colour, with numerous oblique brownish-purple lines; the dorsal fin is blackish, and has thirteen spinous rays; the caudal fin, or tail, is yellow with two black bands; the anal fin is blackish with a yellow curved longitudinal band; its margin is also yellow; a broad black vertical band extends through the eye; and the part anterior to this band, as low down as the eye, is of a pinkish hue with yellow streaks. Its length is from six to twelve inches, the scales on the body are large, those on the head are rather small.

The next subgenus, *Chelmon* (Les *Chelmons*, Cuv.), is distinguished by the form of the snout, which is much elongated, open at the end only, and formed by a great elongation of the intermaxillary and under jaw-bones.

C. rostratus, a species which inhabits the fresh waters of India, is of a silvery hue and has five brownish bands; the posterior part of the dorsal fin is furnished with a black spot encircled with white.

This fish feeds upon insects and is remarkable for its mode of procuring them. When it observes a fly or any other insect on a weed, or hovering over the water, it ejects a little drop through its tubular snout with such precision, as frequently to disable the little animal, so that it falls into the water and is devoured.

In those parts where *C. rostratus* abounds it is frequently kept in vessels of water, and affords much entertainment by the dexterity displayed in shooting at flies which are placed on the vessel for the purpose; it generally approaches to within five or six inches before the drop of water is ejected.

The subgenus *Heniochus* differs from the true *Chætodons* in having the anterior spines of the back produced into a long filament which is sometimes double the length of the body.

Ephippus may be distinguished by the species having the dorsal fin deeply cleft between the spinous and soft portions. The spiny portion, which is scaly, when not erected, is received into a groove formed by the scales of the back.

Holocanthus, the species of this subgenus, have a large spine on the angle of the preoperculum, and most of them have the edge of the same bone serrated; they are found both in the Atlantic and Pacific Oceans.

The next subdivision, *Pomacanthus*, have the body of a more elevated form, owing to the sudden rising of the anterior margin of the dorsal fin. The only species known are from the American coasts.

In the last subdivision, *Platax*, the species are distinguished by the extremely compressed form, the large ventral fin (which has the

cauled in the membrane, the big ventral fins, and Here, in addition to the fine, thickly set teeth, there are in front which are prominent and each of them divides into three points.

All the species of this section are found in the Indian Ocean; one has been found in a fossil stratum in the Antarctic Pole.

Platax vespertilio will afford an example of this section. It is found off the coast of Ceylon, and is of a yellowish colour; the dorsal, anal, and ventral fins are brownish, the back is also mottled with the same colour, and a dark band extends downwards through the eye; the base of the caudal fin is dark brown. This species grows to a large size, and is found in rocky situations, but more commonly in deep water.

[*Platax vespertilio*]

The two species of *Chaetodon*, of which figures are here given, have been selected from Mr. J. W. Bennett's 'Fishes of Ceylon,' a work illustrated by beautiful coloured plates. (Cuvier's *Règne Animal*; Lacépède, *Histoire Naturelle*, &c., des Poissons; Bloch, *Histoire Naturelle, générale et particulière, des Poissons*.)

CHAFFINCH. The English name for the well-known species of *Fringilla*; *Strix* (Spiza) of Aristotle and the Greeks; *Fringilla* and *Prigilla* of Gesner and others; *Franguello*, *Franguello*, *Franguello*, and *Spincone* of the Italians; *Pinson*, *Pinçon*, *Grinson*, and *Quinson* of the French; *Fink*, or *Bach-fink* (Beachfinch), *Edelfink*, *Gemeine Fink*, *Schildvink* of the Germans, &c.; *Pincke* and *Bofincke* of the Fauna Suecica; *Ascellarian*, *Hinc* of the ancient British; *Fringilla caelebs* of Linnæus.

We should have referred this pretty bird to the article *Fringillide*, were there not some qualities belonging to it which seem to be not very well known in this country, that make it worthy of a more particular notice. As far back as the time of Belois its powerful voice was remarked. 'On garde en cage pour le faire chanter, dont le chant est si agréable, qu'il en est fascieux, (folio 1553)—and in the small quarto (1557) the following quatrain is printed under the figure of the bird—

Pour bien pincer, on me nomme Pinçon,
Qu'il a le bec fort hautaine et puissante,
Je lui le chant, l'odeur m'est plaisante;
En ce contraire est à tous ma façon.

'The passion for this bird,' says Bechstein, in his *Cage Birds*, 'is carried to such an extent in Thuringia, and those which sing well are sought for with so much activity, that they are almost always sold for a high price.'

* Professor Montagu's Dictionary has changed the name of *Pinson* to *Pinçon*. The Rev. L. Jenyns in his *Manual of British Animals* has retained the Linnæan name adopted by most authors.

found throughout the province. As soon as one arrives in a neighbourhood where the notes appear good, all the bird-catchers are after it, and do not give up the pursuit till they have taken it. This is the reason why the chaffinches in this province are so indifferent songsters; the young ones have only bad masters in the old ones, and they in their turn cannot prove better.'

In England, however, it appears to have been appreciated. The Hon. James Barrington, in his paper 'On the small Birds of Flight' (the bird-catcher's expression), observes that the greatest sum he ever heard given for a young-bird which had not learned to whistle tunes, was for a guinea for a chaffinch that had a particular and peculiar note, under which it was intended to train others. The same author observes, in his memoir 'On the Singing of Birds,' that the bird-catchers prefer the song of the Essex chaffinches.

Bechstein, after describing the different notes that express its passions and wants, among which the often-repeated cry, *fink*, *fink* (our *twink*), from which its German name is derived, he considers to be mechanical and involuntary, thus speaks of its powers. 'But what makes it appear to still more advantage among other birds are its elegant trilling tones, that seem almost to approach to words. In fact, its warbling is less a song than a kind of *battlement*, to make use of a French word, and is expressed in German by the word *schlug* (trill), which is used to designate its song as well as the nightingale's. Some chaffinches have two, three, four, even five different *battlements*, each consisting of several strains, and lasting several minutes. This bird is so great a favourite in Germany, that not a single tone of its voice has escaped the experienced ears of our bird fanciers. They have observed its nicest shades, and are continually endeavouring to improve and perfect it. I confess I am myself one of its warmest admirers; I have constantly around me the best songsters of its species, and if I liked, could write a good sized volume on all the details of its music.'

The following chaffinch songs, or melodies, are most esteemed in Saxony and Hesse. Some are heard in the woods, but they are rarely sung with a clear and strong voice. If the bird executes well, and adds to the last strain the sound '*fink*,' which the German bird-catchers translate by *apen*, it is of the highest value. 'No price,' says Bechstein, 'will be taken for it.'

1. The 'Double Trill of the Hartz,' in Lower Saxony. 2. The 'Reiter zong,' or 'Rider's Pull,' first heard among the mineral mountains of Saxony and England. 3. The 'Wine Song,' with the following subdivisions, viz.:—The 'Fine,' or 'Längsfeld Wine Song'; the 'Bad Wine Song,' and the 'Sharp Wine Song,' which is subdivided into the 'Common Sharp,' and the 'Ruhl Sharp.' 4. The 'Bridgiam,' or 'Bridegroom Song,' also divided into good and bad. 5. The 'Double Trill.' One of these, the 'Double Trill' of Iamblach, is only to be acquired in the house, and is so deep and powerful that it can scarcely be conceived how the larynx of so small a bird can produce such sounds. Bechstein, who makes this observation, adds, that a bird which sings this either alone, or with the good 'Bridegroom's Song' (such as are educated at Iamblach), sells at Waltershausen for 18 French francs. 6. The 'Gitar,' or 'Good Year Song,' with two subdivisions. Chaffinches singing this, united to the 'Wine Song' of Ruhl, or the 'Sharp Song,' had become very rare when Bechstein wrote, and fetched high prices. 7. The 'Quakia Song,' formerly much admired. Bechstein says, 'I believe I possess the only bird that is now to be found which sings this. It is admired, the 'Quakia' must be united with the double trill. This my chaffinch sings also.' 8. The 'Trewethia,' a very uncommon and agreeable song, never heard but in the depths of the Thuringian

Our limits will not permit us to do more than give the following account of the first and most esteemed of these songs, 'The double Trill of the Hartz,' from Bechstein. This is composed of six strains, rather long, the last of which is ended by dwelling on the *weingeh*, which I shall express here, says Bechstein, by the word *weingeh*. 'I doubt if ever a bird in its wild state has executed this so perfectly as I heard it at Ruhl and at my own house. Art has certainly created it. It is undoubtedly that a chaffinch attained it with the best ability. It has not been instructed from its youth. Hardly can it

* Literally, says the translator, 'to go to the win if it produces a song.'

give it complete without leaving any part out. A full account a high price must be given. A little prod that sings it through the entire, and a little strength. Ruhl, Bechstein & Co. in a note, is a large manufacturing village in Saxony, the inhabitants of which, mostly cutters, have a passion for chaffinches that some have gone nine miles from home to take with bird-me one, these birds distinguished by its song and have given one of their cows for a fine songster: whence has arisen their common expression, 'such a chaffinch is worth a cow.' A common workman will give a louis d'or (sixteen shillings) for a chaffinch he admires, and willingly live on bread and water for a guinea of money. An amateur cannot hear of one that sings in a superior style. The double Trill of the Harz without being in an ecstasy. I have heard them say that one which sings this melody perfectly can certainly converse, from its pronouncing the syllables so distinctly.

For the different modes of capturing this pretty bird, so precious when in perfect song to the bird-fancier, its treatment in confinement, the diseases to which it is subject, and their remedies, we must refer the reader to Bechstein's little book above quoted; but we must notice one peculiarity, viz., the necessity of teaching them their song every

The following description—and the bird is so common that a more particular one is unnecessary—is from the interesting 'Journal of a Naturalist': 'The male bird is remarkable for the cleanliness and trimness of his plumage, which, without having any great variety or splendour of colouring, is so composed and arranged, and the white on his wings so brilliant, as to render him a very beautiful little creature. The female is as remarkable for the quiet unobtrusive tints of her dress; and when she lies crouching on her nest, elegantly formed of lichens from the bark of the apple-tree, and faded mosses, she would hardly be perceptible but for her little bright eyes that peep with suspicious vigilance from her covert.' Temminck says, that in autumn after the moult, the colours of the plumage of the male are more bright than they are in the spring, because all the feathers of the upper and lower parts are terminated by a clear ash-colour; and, at the season of love, the male bird's dress becomes decked with pure and brilliant colour, without the aid of a second moult, the edges of the barbs being worn away with use, and thus suffering those colours which had been hidden to appear in all their beauty.

Varieties.—Pure white, yellowish white, some parts of the body white. The usual colours with a white collar; wings and tail white. Aldrovandus mentions one partly yellowish and partly blackish.

Geographical Distribution.—Temminck says that it inhabits almost all the countries of Europe; that it is permanent in the southern parts, and a regular bird of passage in the greatest number of localities. C. L. Bonaparte, prince of Musignano, says that it is very common near Rome, and makes its passage in October, when numbers of them are taken for the table among other small birds at Paris; and Roccoco, but in much the larger proportion, 500 chaffinches being, according to the prince, captured to every 80 linnets, 65 goldfinches, 30 greenfinches or greenfinches, &c. &c. Selby thus speaks of its migratorial habits: 'All the British ornithologists describe this species as permanently resident with us, and nowhere subject to that separation of the sexes, and the consequent equatorial movement of the females, which is known to take place in Sweden and other countries. The fact, however, is otherwise, as the experience of a series of years has evinced that these birds, from a general point of view, obey the same natural law in their migration of England. In Northumberland and Scotland, the migration takes place about the month of November, and from that period till the return of spring, few females are to be seen, and those few always in distinct societies. The males remain and are met with, during the winter, in immense flocks, feeding with other granivorous birds in the stubble lands, as long as the weather continues mild and the ground free from snow; and resorting, upon the approach of a storm, to farm-yards and other places of refuge to seek supply. This separation of the sexes I am induced to believe takes place in many other species, with respect to their migratory movements, as I have before remarked in the account of the Goldfinch. This appears also to be the case with the Pigeon, having observed that the first flight of these birds (which seldom remains longer than

to recruit, and the sexes separated) consists of females; whilst, on the contrary, subsequent and later flight (which continues with us) are principally composed of males. It has been noticed by several authors that the arrival of the males, in a number of our summer visitants, precedes that of the females by many days; a fact from which we might infer that in such species a similar separation exists between the sexes during their equatorial migration.' Knapp (*Journal of a Naturalist*) says, 'With us (Gloucestershire) the sexes do not separate at any period of the year, the flocks frequenting our barn-doors and homesteads in winter being composed of both. In the northern parts of Europe, however, the females are said to migrate to milder regions, which induced Linnæus to bestow the name of *calcebs* upon this species.' White observes upon the vast flocks which pass near Selborno towards Christmas, all of which were hatched. Jenyns says that it collects in flocks at the approach of winter, but makes no mention of the separation of the sexes. In Middlesex we have seen in winter flocks composed mostly of females, but we have also seen both sexes, about Christmas, partaking with other little winged pensioners of the crumbs daily thrown out for their support.

Food, &c.—Seeds principally. We are compelled to add that they are very injurious to the florist and gardener. 'These birds,' says Knapp, 'make sad havoc with some of our spring flowers; and the polyanthus, in March sheltered borders, is very commonly stripped of all sows by these little plunderers, I suppose to obtain the immature seeds at the base of their tubes.' *** At this period too they are sad plunderers in our kitchen gardens, and most dexterously draw up our young turnips and radishes as soon as they appear upon the surface of the soil; but after this all depredation ceases, the rest of their days being spent in sportive innocence. Selby says that in summer it feeds much upon insects and larvae, and that he has witnessed its assiduity, during the autumn, in devouring the females of a large species of aphid, that infests the trunks and stronger branches of the larch and some other kinds of fir. In winter, he adds, grain and other seeds constitute its food.

Nest, &c.—One of the most beautiful, and, as Selby observes, always accordant with the particular colour of its situation. * It is variously placed in trees and bushes. In orchards, an old apple tree is a favourite situation. Eggs, four or five, bluish white tinged with pink and marked with streaks and spots of purplish-red.

This bird is barely known by the appellation of chaffinch in some countries, and we therefore give its provincial names: spink, beechfinch, piuk, twink, skelly, shell-apple, horsefinch, scobby, shiffa.

CHAGRE, or, according to Lloyd, Chagres, is a river in the republic of New Granada in South America. It traverses in a longitudinal valley a considerable portion of the Isthmus of Panama, rising in about 79° 10' W. long., and 9° 10' N. lat., among the high mountains which approach the Bay of Mandinga. Its course is westward: nearly opposite the town of Puerto Bello it receives the Pequeni, which comes from the S.W., and is as large and broad as itself. After this junction the river is considerable, and may be navigated by canoes; but the navigation is dangerous owing to the number of falls or rapids, in some of which the stream runs with extraordinary velocity. This rapidity gradually diminishes, and at Cruces, a small town situated 23 miles direct distance from the sea, and 44 by the river, it seldom exceeds 3 or 3½ miles per hour, even in the rainy season. Here the river becomes navigable for large river barges. It afterwards gradually declines to the N., sensibly diminishing in rapidity, and enters the Caribbean Sea at Chagre, a small sea-port, 80° 10' W. long., with about 1000 inhabitants of a mixed race. The whole course of the river hardly exceeds 80 or 90 miles.

This small river has acquired considerable importance by having become the means of facilitating the commercial intercourse between Europe and the countries of South America on the Pacific Ocean. The road between the town of Puerto Bello and Panama is a series of steep ascents and descents, and quite impracticable during the rainy season. This circumstance, added to the extremely unhealthy climate of Puerto Bello, has been the cause of the entire

* Temple seems to doubt this. See his description of the bird in his edition of *Ornithology*.

abandonment of this road, and in its place a new communication has been opened between Panama and Chagres. The goods are brought on mules from Panama to Chagres, where they are embarked in river-barges of considerable burden, and carried to the town of Chagres. The port is a little sandy bay, with a ledge of rocks across its entrance, which has not more than 15 feet water in the deepest places, and in many parts rises to the surface. Though the transport of articles by this way is rather expensive, it is still used for goods which are not too bulky or heavy, and is likely to continue until a more easy and expeditious communication is formed. (Lloyd in *Linn. Geogr. Jour* Humboldt; Haigh.)

CHAILA. (Zoology.) [PALAMEDEIDÆ.]

CHAILLETTIA Cuv., an obscure natural order of petalous oysters, some of whose species are said to be poisonous. They are very near Rhamnacæ, from which they differ in having the stamens alternate with the petals, and five hypogynous glands. The petals are small scale-like bodies stationed at the orifice of a tubular calyx; the ovary is superior, and two or three celled, the ovules pendulous, the fruit somewhat drupaceous, and the seeds without albumen.

[*Chailletia pedunculata*.]

1, a peduncled flower; 2, the back of ditto; 3, a petal; 4, stamens; 5, different views of the ovary; 6, different views of the fruit; 7, an embryo.

CHAILLOT, formerly a village in the immediate vicinity of Paris, from the main river which it is separated by the Champs Elysées: it constituted a suburb of Paris by Louis XIV. in 1659: its church is now a chapel of ease to the parish of La Madeleine. It is built on an eminence on the right bank of the Seine, and presents, when viewed from that river, a pleasant appearance. The salubrity of the air and the agreeableness of the prospects have led to the erection of many country houses in it: the gardens of some of these slope down to the river. It had formerly several religious houses. The celebrated carpet manufactory, called the Savonnerie, is in ChailLOT. There is a machine for supplying water in cases of fire, the *Fontaine à feu*. This machine, which is worked by steam, draws water from the Seine, which, after being purified in four reservoirs, is distributed to various parts of the town by a main pipe of cast-iron, one (French) foot diameter. This machine was invented in 181, but has since been much improved. The remains of a Roman aqueduct or subterranean water-course have been discovered at ChailLOT: it conducted water to a basin situated where is now

the Palais Royal. (Dulaure, *Hist. de Paris*, and *Hist. des Environs de Paris*.)

CHAIN CABLES, or iron cables, are of recent introduction. The use of cables made of hemp had long been acknowledged, but the supply of this material had become uncertain, in consequence of the last war, that any other was made to obtain an efficient substitute. The necessity of the old cables to be destroyed, by chafing in rocky anchorage grounds, frequently occasioned the loss of shipping. The necessity of anchoring in such unfavourable places might occur several times in the course of a long voyage, and not only would danger be incurred on each occasion, but there was a risk of a ship being compelled, in order to the loss of anchors, to pursue her course destitute of the usual means of security. The action of the water upon hemp, and its being alternately exposed to the air and water, rendered in time the strongest cables rotten and insecure. The idea of substituting iron cables first occurred to M. Bourgainville, who made a voyage round the world, an account of which was published in 1771. The idea was not taken up until 1808, when Mr. Slater, a surgeon in the navy, took out a patent for a chain-cable. Its merits were not much valued until 1812, when Brown, who had made experiments with chain-cables, enabled him to form a just opinion of their advantages, published the results, and thus directed the attention of naval men to their superiority. The Admiralty soon after ordered them to be tried in the navy. In 1812 Mr. Brunton obtained a patent for further improvements; and after the war he enjoyed a *brevet* for importing chain-cable into France, but the advantages which he derived from it were so small that he relinquished his privilege.

Chain-cables are now furnished with bolts at the distance of a fathom or a couple of fathoms from each other, by withdrawing which a ship may slip her anchor in case of necessity with less trouble than was formerly required in cutting a strong hempen cable. A plan has also been contrived which prevents the anchor and cable from acquiring too great a rapidity of descent when the anchor is let go. The strength of every part of a chain-cable is fully proved by machinery before it goes out of the manufactory. The weight of the cable when the ship is at anchor is advantageous, as the strain is exerted on the cable rather than the ship, and must be excessive to draw the cable into a straight line. Instances have occurred of ships enduring a violent storm of several days' continuance, during which thirty or forty fathoms of their iron cables have been completely polished by contact with rocks and other rough materials. Under such circumstances a hempen cable would have been chafed to pieces, and the vessel inevitably lost. The use of chain-cables is now becoming universal in the mercantile service as well as in the royal navy; and in the 'Report of a Committee of the House of Commons on Shipwrecks,' (presented August 15th, 1836,) no allusion is made to the occurrence of shipwrecks arising from defective cables: though formerly many originated from this cause. The use of chain-cables has been indirectly encouraged by the circumstance that a vessel provided with these improved means of security can be insured on more favourable terms than those which are without them.

CHAIN (in surveying) is a measuring line of 100 links, altogether 4 poles, or 66 feet, or 22 yards, 1 inch, so that ten square chains make an acre. It is commonly called Gunter's Chain, having been first used by him, and described in his treatise on the cross-staff, &c. in the following words: 'We may measure the length and breadth by chains, each chain being four perches in length, and divided into 100 links, then will the work be more easy in Arithmetick. For as 10 to the breadth in chains: so the length in chains to the it in acres.'

Chain is of universal use in land surveying; but care must be taken to verify its length from time to time, since the material is very extensible, and the apparatus must necessarily be roughly used. It is stated in the account of Troughton (*Ast. Soc. Monthly Notices*, Feb. 1836), that the chains of two surveyors, who differed in their measurement, being sent to him, one was found two inches too short, the other three inches too long.

CHAIN SHOT. Two iron balls linked together by a chain eight or ten inches long, and called. They are used in naval actions.

CHALAZA, that part in a seed where the vessel of

the raphe pass from the exterior integument of the ovule, and expand into the secum line. In the common almond it is readily seen by the testa, and is not out and observing that part which corresponds to the apex of the cotyledons. When the foramen of a seed is next the hilum, the chalaz is most conspicuous; but when the foramen is at the apex of the seed, the chalaz will then be in contact with the hilum, with which it must necessarily be then confused.

CHALCEDON, properly **CALCHEDON**, a town of Asia Minor, on the coast of the Propontis, and at the entrance of the Bosphorus, nearly opposite Byzantium. It was built by a colony from Megara, 675 B.C. The earliest history of Chalcedon is connected with that of the neighbouring Megarian colonies. [BYZANTIUM.] It was taken by the Persians, retaken by the Athenians, then recovered its independence, and entered into a confederation with Byzantium and other neighbouring cities. It was afterwards subject to the kings of Bithynia; and lastly, under the reign of Valens, the Chalcedonians having embraced the part of the prefect Procopius, Valens, after his victory over the latter, ordered the walls of their town to be razed. In

history Chalcedon is known for its council held 451, which was attended by 630 bishops from both the east and the west. It was the fourth œcumenic or general council of the church, those of Nicaea, Constantinople, and Ephesus having preceded it, and was convoked by the Emperor Marcianus. It was the first council at which the bishop of Rome, then Leo I., called the Great, held the presidency by means of his legates. The council condemned the heresy of Eutyches on the nature of Jesus Christ. By the 28th canon of the same council, the see of Constantinople was declared to be equal in dignity, though next in place, to that of Rome, and full jurisdiction was given to it over the churches of Thrace, Asia, Pontus, and other eastern provinces. The legates of Rome opposed this canon, which however was passed by the bishops and approved by the emperor.

Chalcedon is now a poor village, inhabited chiefly by Greeks, two or three miles south of Scutari, on the site of the ancient Chrysopolis.

CHALCIDES, Daudin's name for a family of lizards, which like the seps-lizards are very long and serpent-like: but whose scales, instead of being imbricated or disposed like tiles, are rectangular, and form like those of the tail in the ordinary lizards, transverse bands which do not intrench upon each other. Some, says Cuvier, have a ridge on each side of the trunk, and the tympanum still very apparent. They approach the *Cordylæ*, as the seps-lizards approach the *Sauri*, and lead by several relations to the *Sheltopu-sarke* and *Ophisauri*. The Chalcides have four legs, but they are little developed, and the extremities may be considered as in a degree rudimentary; for some of them cannot be said to be furnished with more than one well-formed toe on each foot, though there are traces or rudiments of more. Cuvier thus arranges the family:—

A species with five toes from the East Indies, *Lacerta* of Linnaeus.

A species with four toes, *Lacerta tetradactyla* of Lacépède; *Chalcis tetradactyla*. The genus *Tetradactylus* of Merrem; *Sauropsis* of Fitzinger.

A section which have the tympanum concealed, and leading directly to the *Bimani* (*Chirotes*), and thence to the *Amphibiana*. Of these, there is

A species with five toes, forming the genus *Chalcides* of Fitzinger.

A species from Brazil, with four toes before, and five behind, *Heterodactylus imbricatus* of Spix.

A species with four toes on each foot, forming the genus *Brachypus* of Fitzinger.

A species from Guiana, with five toes before, and five behind, "but reduced to small tubercles so little visible that the species has been regarded at one time as having three toes, and at another as having but one." Cuvier adds, that on the first supposition, it is the *Chalcide* of Lacépède, pl. xxxii.; the *Sauropsis* of Schneider; the genus *Chalcis* of Merrem; and the genus *Cophias* of Fitzinger; and that upon the second hypothesis, it is the *Chalcide monodactyle* of Daudin; the genus *Cholobus* of Merrem; but, adds Cuvier, these genera resolve themselves into a single species.

To give *Chalcis tetradactyla* as an example of the family.

[*Chalcis tetradactyla*.]

CHALCIDICUM, an apartment separated by a partition from the body of a basilica or other large building. The name, Festus says, is derived from the city Chalceis. Vitruvius (v. l.) directs that chalcidica should be constructed at the ends of a basilica, if the area is disproportionately long. [BASILICA.] A building has lately been discovered in Pompeii, which appears to be a chalcidicum from the inscription:—

Funeraria L. F. Sacerd. Public. Nomine. Svo. Et.
M. Kv. Frontonis. Fili. Chalcidicum.
Cryptam Porticum Condidit Augustus.
Pretati. Svo. Populna. Fy. Et. Eudomque.
Dedecavit.

The chalcidicum is, in this instance, considered to be an inclosed space at the end of the open area of the building, in the centre of which space a large semicircular recess has been formed. The entire structure, at Pompeii, consists of a large area, about 130 feet by 60, surrounded by a double gallery, and has in front a pseudo-ipterostyle of eighteen columns elevated on pedestals. At the centre of the portico was the great public entrance, which was closed with folding doors, turning in sockets of bronze, and secured by bolts. On each side of the entrance there are two large circular recesses, and beyond these again are raised platforms, the staircases to which still remain. By a reference to the plan, in *Pompeii* (p. 100, vol. i.), and to the cut below, the large area of this building will be seen, with the solid of the floor places for exhibiting goods, possibly cloth, for sale. The area was surrounded with beautiful marble colonnade. Under the colonnade at the end opposite the entrance is the large recess (A), with a recess (B) adjoining, which is considered to be the chalcidicum, and possibly was a commercial tribunal, or perhaps a place for ratifying mercantile contracts, &c. Behind the colonnade

[Plan of the Chalcidicum, Pompeii.]

is a gallery, or cryptoporeus (C), either for water use or a depository for food. At the back of the chalcid, there is a passage entrance (D) leading into the cryptoporeus; and near this entrance into the cryptoporeus is a statue of a certain *Chalcidia*, erected by *Fullones* (cloth-sealers) of Pompeii to his memory. It is not improbable there was a double gallery over the colonnade and portions, from the circumstance of a staircase at (E).

Some have taken a chalcidicum to be a spacious room, or a portico, but apparently without much reason; the word occurs on the Monumentum Ancyranum, in connexion with Curia and Templum.

CHALCIDIDÆ, a family of Hymenopterous insects, of the section *Pupivora*, Latreille.

Nearly all the species of this group are exceedingly minute. Many of them are very brilliant, their colours consisting of various shades of green, blue, or copperlike hues; in some of the sections, however, black is the prevailing colour. The thorax is usually large in proportion to the body, and the latter is often of a compressed form, and joined to the thorax by a distinct long petiole or stalk, as in *Chalcis clavipes*, which is one of the largest of the British species, measuring from tip to tip of the wings when expanded upwards of half an inch: it is of a dull black colour, and remarkable for the great development of the coxæ and femora of the hinder legs; the latter are of a reddish hue, and armed with eight little teeth beneath; the hinder tibiae are curved. It is found on the leaves of shrubs in marshy situations.

[*Chalcis clavipes*.]

a, the head; b, the hind leg; and c, antenna—magnified d, hind-femur and tibia of a species of *Donacia*.

In the species just described the oviduct is short and hidden beneath the abdomen, a circumstance very common in this tribe: in some, however, the oviduct is very long, equalling or exceeding the body in length. This is the case in the genus *Callimome*, a group the species of which have very brilliant colours, principally green, and deposit their eggs in the larvæ of the gall insects (*Cynipidæ*), an operation which their long bristle-like ovipositors enable them readily to perform: here, as in the genus *Chalcis*, the body is compressed. Many of the species, however, have the body depressed. One of the most striking characters in the Chalcididæ is in the wings, which are almost destitute of nervures. Most commonly there is in the superior wing a single nervure springing from the base and running parallel with the exterior margin for about one-third of the whole length of the wing; it then slopes upwards and joins the margin itself, and a little beyond the part where the slope takes place there is a small short ramification thrown out obliquely, which is generally thickened towards the extremity, and forms a little dark spot. The antennæ are always elbowed, that is, the terminal joints are bent forward at an angle with the basal joint. We have observed that when these little insects are about to leap, which a great number of them have the power of doing, they invariably bend their antennæ under the body, and it appeared that this organ was used in making the spring; if this should be the case, it would be a most extraordinary use to make of parts, which are usually considered either as organs springing or touch. We may observe that the species *Callimome* we found to possess this power in a high degree had immensely thick antennæ, and the hind legs, the usual leaping organs, do not appear at all adapted for that purpose, nor can we discover any other part that is. Although in *C. clavipes* (the species figured) the hinder femora are thick, yet it does not possess the power of leaping; and when we examine the structure of this part, we find that it differs much from the thickened thigh of leaping insects.

It is formed upon the same type as the same part in some of the *Donacia* tribe (among beetles), which appears to be used for climbing. This species inhabits marshy situations, would probably require a similar apparatus for the same reason as the *Donacia* do. The deep furrow from falling into the water. Figure of the leg of a species of *Donacia* is given, to show the resemblance both to the femur and curved tibia.

*The Chalcididæ are all parasitical in their larva state; some are so minute as to undergo their metamorphosis in the eggs of other insects. The chrysalides of some of the lepidopterous insects not unfrequently form a nucleus of an immense number of these little insects. One species of *Chalcis* generally confines its attack to the chrysalis of one species of lepidopterous insects; occasionally we have reared more than one species of the chalcididæ from the same chrysalis.

Mr. Walker, a gentleman who has written much on this group of insects,* looks upon it as a great section of Hymenoptera rather than a family, and his view is far to us correct. The Chalcididæ are divided by him into two sections, which he calls *Chalcides Pentameri* and *Chalcides Tetrameri*, names applied from their having five and four jointed tarsi; each of these sections is again subdivided into several families, the species of which are exceedingly numerous. Mr. Westwood, who, as well as Mr. Walker, has paid great attention to this interesting group, states that there are probably 1500 species in England.

CHALCIS. [EUROPA.]

CHALCONDYLAS, LAONICUS. [BYZANTIUM, p. 81.]

CHALCONDYLAS. [DEMETRIUS.]

CHALDÆA, CHALDÆANS. Chaldæa is, according to Ptolemy (*Geogr.* v. 20), the designation of the southwestern portion of the Babylonian empire, extending along the Euphrates, and as far as the Arabian desert. Strabo, in his account of Babylonia (xvi. c. i., t. iii., p. 437, ed. Tauchnitz), speaks of a tribe (*χάλδαι*) of Chaldæans occupying a country which borders on the Arabs and the Persian Gulf; and he evidently alludes to the same tract of land in describing the limits of Arabia (l. c., c. iv., p. 384), when he refers to 'the marshes (*χάλυ*) in the country of the Chaldæi, which the Euphrates forms by its inundations.' Herodotus (vii. c. 63) merely mentions the Chaldæi as ranked with the Assyrians in the army of Xerxes, without defining the country from which they came. Chaldæi also served as mercenaries in the army of Artaxerxes Mucnon. The ten thousand Greeks, in their retreat after the battle of Cunaxa (B.C. 401), had to pass their territory in the Carduchian mountains, and on the banks of the Kentrites, a tributary of the Tigris. They were armed with large (*γίγνα*) shields of wicker-work and lances; they were free (*ἐλεύθεροι*, Xen. *Anab.* iv. 3, 4; *αὐτόνομοι*, vii. 8, 23, i. e. not subject to the Persian dominion?), and had the reputation of being valiant. Strabo probably intends to speak of these mountaineer Chaldæi of Xenophon, when he says (xii. c. 3, t. iii. p. 26, ed. Tauchnitz) that the Tiberani, the Chaldæi, the Samni, and Lesser Armenia, are situated along the mountain-chain of Skydas above Trapezus and Pharnakia. Gosselin (*Bersch and Gruber's Encyclopædia*, art. 'Chaldæer') and others are inclined to consider these mountaineer Chaldæi as the original stock; some descendants of which, the Casdim of the Old Testament, settled at a remote epoch in the plains around the lower course of the Euphrates, and were for a time subject to the Assyrian empire, but subsequently founded a Chaldæo-Babylonian dominion. Whether these Chaldæi, who descended from the north, belonged to the Shemitic or to the Indo-Persian family of nations, remains doubtful. The language which was spoken at Babylon, and which is always called the Chaldæan language, is of the Shemitic stock; and the names of some Babylonian cities, mentioned by ancient authors, are of Shemitic derivation. If there were sufficient reason to suppose that the worship of these deities originally belonged to a caste of priests among the mountaineer Chaldæi of the north, and that it was introduced by them into Babylonia, the name of the caste would strongly favour the opinion that the Chaldæi of the Carduchian hills were Shemites. Otherwise, the geographical position of these mountaineers seems rather to support the conjecture that they were of the Indo-Persian race. The latter opinion is entertained by Gosselin, who supposes that the primitive name of the *Kerd*, which

* See the *Entomological Magazine*.

nerated into *Cass* (Chaldean) and *Cald* (Chaldean) and this is the origin of the name of the modern Chaldean sources of the civilization. The history of the Chaldeans is partly the fragments of Berossus preserved by Eusebius and Josephus, and partly the books of the Old Testament. According to Berossus, the Chaldeans traced their civilization to a being half man and half fish, which came to them from the Erythrean Sea, where it had its dwelling; a tradition which, when divested of its allegorical shape, seems to attest that the Chaldeans themselves indebted for their first cultivation to them over the sea. Previous to the great flood, Berossus enumerates ten kings of the Chaldeans, the first of whom he calls Alôrus, and the last Xisuthros or Sésithros (Eusebius Pamphilus *Chronicon Bipartitum*, &c., ed. J. B. Aucher, Venet., 1818, 4to., p. 15), and who reigned together 120 sari, or 432,000 years. Xisuthros took refuge from the great flood in a ship, which was driven to the Cordyean (or Coreyrian) mountains. A tradition similar to that of the tower of Babel follows. Eighty-six kings and 3391 years are counted by Berossus, from the great flood to the capture of Babylon by the

According to the Old Testament, the foundation of the Chaldean empire, in the plains of Shinar, was laid by Nimrod, the son of Cush (Gen. x. 8), i. e. the Ethiopian; with this may be compared the tradition of the transmarine origin of Chaldean civilization above alluded to, and an Egyptian tradition recorded by Diodorus (i. c. 28), according to which a colony headed by Belus, the son of Poseidon and Libya, proceeded from Egypt to Babylon. The book of Genesis (xiv. 1) mentions a king of Shinar, Amraphel, who was contemporaneous with Abraham. Then follows a long blank in the history of the country; and the next occasion in which we find it mentioned is during the reign of Hezekiah, king of Judah (712 B.C.), when friendly relations are reported to have subsisted between him and Merodach-Baladan, king of Babylon (2 Kings xx. 12—18; Is. xxxix. 1). Merodach-Baladan is likewise mentioned by Berossus, who says that it was this monarch who made the state of Babylon independent of the Assyrian supremacy. He was succeeded by Belibus, a name likewise mentioned in a list of Babylonian sovereigns preserved by Ptolemy. But three years after his accession Belibus was defeated in war by Saurherib, and Babylonia became again an Assyrian province, governed by Esarhaddon (Assaraddinus), the son of Belibus. A new epoch begins with Nabopolassar, the father of Nebuchadnezzar. Assisted by the governor of Media, Nabopolassar threw off the allegiance to Assyria (B.C. 625), destroyed Nineveh, and asserted his authority in Syria against Pharaoh Nechoh of Egypt (2 Kings xxiii. 29, 30; 2 Chron. xxxv. 20, &c.; comp. Herod. ii. c. 159). He was succeeded (B.C. 604, according to the computation of the Ptolemaean canon) by his son Nebuchadnezzar, who extended his conquests as far as Egypt; Megasthenes says (Strabo, i. c. 1, t. iii., p. 231, ed. Tauchnitz), as far as the pillars of Hercules. He undertook three expeditions against Jerusalem, the last of which terminated with the capture of that city after a siege of two years; but he was unable to take Tyrus. He died in 562 B.C., and was succeeded by his son Evilmerodach, who in the second year of his reign was slain by Neriglissar, his brother-in-law. The reign of Neriglissar lasted four years, at the expiration of which he was followed by his son Laborsorarchod, or Labassorascus, who after nine years fell a victim to a conspiracy. Nabonitus, or Nabonid, the Belshazzar of the Old Testament, succeeded him. This is the sovereign in whose reign Babylon was subject to the Persians. (Herod. i. c. 188.)

The Chaldeans were absolute despots, and their empire was divided into several provinces, which were under the control of governors different in rank. The religion of the Chaldeans was Sabæism, and consisted especially in the worship of the sun, moon, the five planets, and the twelve signs of the zodiac. The worship of these heavenly bodies led to astronomical observations, and to a regular system of time. Herodotus attests (ii. c. 109) that the Chaldeans received from the Babylonians the division of the year into twelve parts (years). It seems that the same was used for all ordinary purposes; but for astronomical observation they employed a moveable solar year. The constitution of the latter, and its divi-

sion into months, appear to have been very recent, and a group of the Egyptians (Ideler, *Lehrbuch der Chronologie*, Berlin, 1831, 8vo., p. 55, &c.) Astrology was much cultivated among the Chaldeans. The planets Bel (Jupiter), Meni (Venus), and Merodach (Mars) were considered to be of good, as the planets Merodach (?) and the stars of evil omen; the influence of Nebo (Mercury) depended on its position. To draw conclusions as to the future destinies of men from the position of the stars at the hour of their birth, to interpret dreams, or found predictions on the flight of birds, solar or lunar eclipses, earthquakes, and other natural occurrences, was a principal occupation of the caste of the priests, which propagated its wisdom by tradition from father to son. (Diodor. Sic. ii. c. 29.) They pretended that their astronomical observations had commenced 473,000 years before the time of Alexander. (Idem, c. 31.) The belief in an unalterable divine predestination was an essential part of their faith (Idem, c. 30); and according to Ephraim Syrus, this doctrine was still prevailing in Chaldea during the fifth century of our era.

The situation of the Chaldeans near the mouth of the Euphrates and Tigris was particularly favorable to commerce; and we find accordingly that they were one of the most distinguished trading nations of antiquity. They were in communication with India, partly by caravans over land, and partly by sea through the Persian Gulf. The principal articles imported from India were precious stones, dyes, pearls, wood for building ships, and cotton. Herodotus (i. c. 192) mentions that the revenue of four large villages in the plains round Babylon was appropriated to the feeding of Indian hounds, which must consequently have been imported in considerable numbers. Babylon itself was famous for superior linen, woollen, and cotton cloth, and for carpets; and Herodotus also observed that seal-rings and walking-sticks, with the handles ornamentally carved, were much in use among the Babylonians, which proves that the art of carving in stone and wood must have been generally cultivated.

(Hœren, *Ideen*, &c., vol. i., part ii., p. 199, &c.; Winer, *Biblisches Realwörterbuch*, 2nd edit., vol. i., p. 253, &c.; Gesenius, in *Ersch und Gruber's Encyclopædie*, art. 'Chaldæer'.)

CHALDRON, a measure, containing 36 bushels, heaped measure. The word appears to come from *caldarium*; in French *chaudron*, or *chaudrière*. Richelet observes that brewers, sugar-refiners, dyers, &c., make use of the *chaudrière*. Its proper signification, of a large metal vessel, or boiler, was probably transferred among us to denote a large measure of capacity.

CHALICOTHE RIUM, a genus of fossil pachydermatous animals allied to the Tapirs, comprising two species found at Epplesheim, about 12 leagues south of Mayence, in sand, supposed to be of the second tertiary or Miocene period of Lyell. (See Kaup's *Description d'ossements fossiles*, Darmst., 1832.)

CHALK (in Geology), a rock which forms the highest part of a series or group termed cretaceous. [CRETACEOUS GROUP.]

Chalk is composed of nearly 44 parts of carbonic acid and 56 of lime. It is extensively used in agriculture, to improve various soils. The best land for the growth of wheat contains a certain portion of argillaceous, siliceous, and calcareous earth; and when this last is deficient, the addition of chalk improves the soil more than any quantity of animal or vegetable manure could do alone. Lime produces a greater effect by its caustic nature; but as it is always put on the land in much smaller quantities than chalk, it does not so permanently improve it. Good chalk should be firm and compact, should break readily, and crumble into a fine powder; it should readily absorb moisture, and when the clumps are exposed to frost after having been wet, they should break into minute square fragments. Chalk is called a manure, and it is in as far as everything which increases the crop may be so called; but it is a great mistake to suppose that it may so far supersede dung that where it is used the latter may be dispensed with; but its chief use is to improve the texture of the soil, and render it better adapted to receive and retain moisture, so that a smaller quantity of dung will have a greater effect.

A good agriculturist will not neglect to use chalk on poor land, although he may not think the soil is full of vegetable matter. In this last case however, he would

be each more equal; but chalk will make dung wet, well, and hence it is most frequently mixed into a compost with it, or alternate heaps of dung and chalk are put upon the land and mixed in the spreading. When chalk is used, it is of great importance to ascertain whether the natural soil contains more or less of calcareous matter. The less of this matter is found in it on analysis, the greater improvement is produced by chalk; hence the common saying, that the farther you are from a chalk-pit, the more valuable is the chalk.

The soils most improved by it are the strong wet clays, which contain a portion of iron. Chalk acts as an absorbent, corrects a triugency, and prevents, by its interposition between the particles of clay, that running into a solid mass, which is so detrimental to the roots of plants by entirely excluding atmospheric air. On loose sands its effect is different; there it acts chiefly as a cement, and the more argillaceous it is, the better it binds the siliceous particles. For light soils marl is preferable, especially when a considerable coat can be put on the land. The clay which is so abundantly used in some parts of Norfolk, and is found in many places at a small depth below the surface, owes much of its virtue to the calcareous matter which it contains, and where this is deficient, it will not much improve the soil until chalk or lime be added. Chalk is used wherever it can be procured within a moderate distance, and the soil is stiff; as in the counties of Essex, Suffolk, Berkshire, Middlesex, Buckinghamshire, and many others. In those districts where chalk is much used, it is generally put on the land in autumn, and not ploughed in till it has been exposed to the frost; or it is laid in long heaps on a headland, or by the side of a road or lane, and there turned over and mixed with the earth on which the heaps are laid. If it be exposed to the sun in summer, it must be carefully covered with earth, or it will harden so much by drying that it will be very difficult to pulverise it afterwards, and the frost will not have the same effect upon it. Ten tumbril loads of chalk, and as many of good farm-yard dung, are a very good dressing either on a fallow for wheat or previous to sowing turnips. When chalk is laid on permanent meadows, it promotes the growth of white clover; but except the meadows are wet and produce rushes, it is of no very great benefit to the grass, although it shows its effect when the grass is broken up. When land is cultivated according to the convertible system, the best time to put chalk on the land is when it is about to be ploughed up. If the grass is fed off the last year, the chalk may be put on during the preceding winter, and simply spread over the grass; it will thus be pulverised by the frost, will sweeten the pasture, and its full effect will be perceived in the first grain-crop after the land is ploughed up. When chalk has been some time in the land, it is gradually carried below the soil by the filtration of the surface-water. After a few years therefore it requires to be renewed, which shows the advantage of putting on a moderate quantity and repeating it in six or seven years, in preference to putting on a large quantity at once, unless where lands are reclaimed from a state of waste, and require to be improved by a large admixture of calcareous matter before they can be made productive by enriching manures. This is the case with those yellow loams which contain much iron, and which are generally found under the *iron pan*, so well-known to all those who improve poor light heath-land. [BARKEN LAND.]

An important use of chalk is to form ponds in porous soils for the use of cattle. A stratum of chalk a few inches thick, protected by a coat of gravel and sand to prevent its being trod through, will effectually retain the water; and if a considerable proportion of salt is beat up with it and intimately mixed, it will effectually prevent worms from making lodgements in it, and keep in water for a very long time. It is an advantage to throw chalk into all ponds used by cattle; it corrects any acidity which may arise from stagnation, and the water in which chalk is diffused is more wholesome than that which contains clay alone. In fattening calves chalk is of the greatest use; it may be laid in half-pens for them to lick, which they will readily do, or it may be scraped and mixed with a small quantity of salt, and laid in a small manger within the reach of each calf. It not only prevents scouring, and keeps their digestion in a good state.

In many parts of the island the whole sub-soil to a great depth is a solid mass of chalk, and the earth which covers it contains very little else than carbonate of lime, with a small

table matter in a decomposed state. In this chalky sweet herbage grows, and is a very useful sheep; accordingly the chalk hills of Wiltshire, &c., are the best pastures. On the sides of the hills where the waters continually accumulate the fine particles of the soil which are washed down from above, some very productive arable lands are formed, and very good crops of barley are raised. There is a plant which seems to delight in chalky soils, and to flourish better there than in deeper and richer soils. This is the saintfoin (*Hydesarum Onobrichis*), and its introduction among the cultivated grasses has greatly raised the value of chalky land, previously considered too poor to repay cultivation. It not only produces an excellent fodder, superior to meadow-hay and scarcely inferior to clover, but by its roots it so divides and enriches the soil, that after having covered it with luxuriant crops of hay for several years, it leaves it in a fit state to produce excellent crops of grain, with very moderate manuring.

Chalky soils are not subject to the same perennial weeds which infest richer lands; couch-grass is seldom found in chalk, but the annuals, such as May-weed, charlock, poppy, crow-foot, and several others, abound in it. When a chalky soil produces thistles, it is an indication of its containing a portion of argillaceous earth, which improves its fertility.

CHALK STONES. [CALCULUS.]

CHALLENGE. [JURY.]

CHALMERS, DAVID, of Ormond, was born in the shire of Ross about the year 1530. He was bred to the church, and having taken orders at Aberdeen, where he had his early education, he proceeded abroad and studied theology and the laws in France and Italy. At Bologna he was, in 1556, the pupil of Mariannus Sozenus.

On his return to Scotland he was successively appointed parson of Suddy, provost of Croickton, and chancellor of the diocese of Ross. He was then employed in digesting the laws of Scotland, and was principally concerned in publishing the acts of parliament of that kingdom, by authority, in 1566.

On the 26th January, 1565, he was admitted an ordinary lord of session on the spiritual side, on the death of the learned Henry Sinclair, bishop of Ross, and he was also called by the queen to her privy-council. In December, 1566, he obtained a charter of the lands of Castleton, and others in the earldom of Ross, from the crown; 'hir majestie having respect to his gud, trew, and obedient service done in all tymes past to hir majesties honour, will, and contentment, not only in this realm, bot in sik foreyn countries as it plesit hir hienes to command him, and that therethro he bath put his persoun in perill and danger, and also super expendit himself.' It is remarkable that this was ratified by parliament in April, 1567, which was months after the murder of Darnley, wherein he was commonly accused of being concerned. He is said to have afterwards acknowledged his guilt by a precipitate flight to France. (Tyler's *Craig*, 95.) If so he must soon have returned again; for on the 19th August, 1568, he was forfeited for his assistance to Queen Mary, in her escape from Lochleven (*Act. Parl.* iii. 54); and on the 2nd June that year, his place of a lord of a session was given to Robert Pirairn, commendator of Dunfermline. (*Pitmedden MS.*)

After the deposition of Mary he retired to Spain, where he was kindly received by Philip II., and after some stay in that country he went to France, where, in 1572, he presented Charles IX. his '*Histoire abrégée de tous les Roys de France, Angleterre, et Ecosse*;' a work which was afterwards enlarged with a History of the Popes and Emperors, and dedicated to King Henry III. In 1573 he published his '*Discours de la Legitimé Succession des Roynes, et du Gouvernement des Princesses aux Empires et Royaumes*,' which was meant as an answer to Knox's '*First Blast against the monstrous Regiment of Women*;' and in 1579 he published '*La Recherche des Singularitez plus remarquables concernant l'estat d'Ecosse*,' which he dedicated to Queen Mary.

He soon afterwards returned to Scotland, where, on the 4th September, 1583, was restored by the king to his lands, offices, and dignities. The remission was ratified by parliament on the 22nd May, 1584, but under proviso that it should not cover 'the odious murders of our liege lord's dearest fader and twa regents.' (*Act. Parl.* iii. 54.) He was never brought to trial for these or any other crimes; on the 21st July, 1586, restored to his seat on the bench. He retained his seat till his death, which happened in 1

year 1592, and on the 6th October, 1607, his son William Chaloner was born to his father of Castleton, in other words, the town of Castleton.

CHALONER, WILLIAM, was born at Fochabers, in Elginshire, Scotland, about the year 1742. He received his education principally at the University of Aberdeen; studying law, he went to the British Colonies of America, where he practised at the bar until the breaking out of the revolutionary war. He then returned to Britain, and settled in London. He wrote 'Political History of the United Colonies, from their settlement till 1776,' and 'An Estimate of the Comparative Strength of Great Britain and America,' works are said to have introduced him to an acquaintance with the Board of Trade, which he maintained till his death, May 31, 1825, aged 82 years.

He was the author of 'Caledonia,' a topographical history of North Britain; the lives of De Foo, Thomas Ruddiman, Sir John Davis, Allan Ramsay, Sir James Stuart, Gregory King, and Charles Smith, which were prefixed to editions of, or selections from, their works; and under the name of Oldys, he published a life of Thomas Paine. He also contributed occasionally to periodicals, and published a number of pamphlets, some of them anonymously.

CHALMERS, ALEXANDER, was a native of Aberdeen, where he was born March 29, 1759. His father, who was a printer, and possessed of considerable classical attainments, established the first Aberdeen newspaper. Alexander, after receiving a classical and medical education, left his native town for Portsmouth, intending to join a West India ship to which he had been appointed surgeon; but suddenly altering his intention he went to London, where he settled and maintained himself by his literary labours. He lived in intimate intercourse with most of the eminent London booksellers and printers of his time, by whom he was almost constantly employed, and for many of whom he recorded his esteem, on the occasion of their deaths, in the obituary of the Gentleman's Magazine. He died, December 10th, 1834, aged 75 years.

He contributed largely to the political and literary periodicals of the day, and edited a great variety of works. The chief are, 'The British Essayists, with Prefaces, historical and biographical,' in 45 vols.; 'Shakspeare,' in 9 vols.; the 'Works of the English Poets from Chaucer to Cowper,' in 21 vols.; a 'History of the Colleges, Halls, and Public Buildings of Oxford,' and a 'General Biographical Dictionary,' in 32 vols. (*Gent. Mag.*)

CHALONER, SIR THOMAS, father and son. The elder Sir Thomas Chaloner appears to have been highly esteemed by his contemporaries as a brave, able, and worthy man. He was born in London about 1515, and educated at Cambridge. He was sent, when a young man, with Sir Henry Knevet, to Germany, and attracted attention in the court of Charles V. He accompanied Charles on his expedition to Algiers, and was shipwrecked off the coast of Barbary, and narrowly escaped drowning. On his return to England, he was employed about the court, and was knighted for his conduct at the battle of Musselburgh, in the year 1547. The fall of his patron, the duke of Somerset, affected his fortunes; but on the accession of Elizabeth, he was sent as ambassador to Ferdinand I., emperor of Germany, and was also employed in a similar capacity in Spain. He died October 7, 1565, and was buried in St. Paul's. His literary productions consist of a large collection of poetical pieces in Latin, and some prose works, one of which is 'On the right ordering of the English Commonwealth.'

Sir Thomas Chaloner, the son, who inherited a considerable portion of his father's abilities, was born in 1559. To him is attributed the discovery of the alum mines near Whitby, in Yorkshire, the first that were worked in England. He, at all events, has the merit of having established the working of the mines. Towards the end of Elizabeth's reign, he went into Scotland, and rose so high in James's favour as to be afterwards appointed the guardian or governor of Prince Henry, with the control both of his education and household, an office which he seems to have creditably discharged. He died November 17, 1615. His only literary production is 'A short Discourse of the most rare and excellent virtue of Nitre.'

One of his sons, Edward, entered into holy orders, and became prior of St. Alban's Hall, Oxford. He published a 'Treatise on the Authority of the Church.' Two others, James, were members of the Long Parliament,

and sat as judges on the trial of Charles I. James Chaloner is the author of a 'Description of the Isle of Man,' printed in the original edition of King's 'Book Royal,' though the work has been also attributed to another James Chaloner, a native of Chester. Thomas Chaloner was the author of several political pamphlets, which appeared during the civil wars. (*Brit. Brit.; Chalmers's Dict.; Ormerod's Cheshire; Gent. Mag.*)

CHALONNE. [MAINE ET LOIRE.]

CHALONS-SUR-MARNE, on the right or N.E. bank of the river Marne, from which it is named, is the capital of the department of Marne: it is about 91 miles in a straight line E. or E. by N. of Paris, or 102 miles by the main road through Meaux, Château Thierry and Epernay; there is a somewhat shorter road by Montmirail. It is in 48° 58' N. lat., and 4° 21' E. long.

This town existed during the Roman dominion in Gaul, and is mentioned in the Itinerary of Antoninus under the name of *Durocatalauni*, and by Eutropius under that of *Catalauni*: the prefix *Duro*, from a Celtic word denoting water, indicates its position on the bank of a river. Near this town, A.D. 271, Aurelian defeated the army of Tetricus. [AURELIAN.] In a subsequent age it was marked by another memorable conflict. In the year 451, Attila, at the head of the Huns, who had invaded Gaul, was defeated by the combined forces of the Romans and Visigoths under Aëtius and Theodoric. [ATILIA.] D'Anville conjectures that the ancient name of the town was originally in the singular form *Duro-Catalaunum*. The plural form would be an indication that this town, like many others in France, took the name of the tribe of which it was the capital; but we are not aware that any ancient writer has mentioned such a tribe. Possibly they were a subordinate clan of the Remi whom Cæsar places in this part.

The town stands in the midst of meadows through which the Marne winds. On the east side of the town on the Strasbourg road is a fine promenade called the *Jard*: the planted avenues are magnificent. The town is surrounded by a wall and a ditch. The streets are tolerably regular, and from their neatness give to the town a good appearance, though the houses are for the most part built of wood. The cathedral is chiefly remarkable for its two pyramidal stone towers, which have been by some much admired; the Grecian portico is however by no means in keeping with the rest of the building: the hôtel de ville or town-hall has a handsome façade, adorned with four columns; the hôtel or office of the prefecture is distinguished by the simplicity of its architecture.

Châlons had, in 1832, a population of 12,413. It is a town of considerable trade, being on the road from Paris to Strasbourg and the eastern departments, at the point where it is crossed by the road from Reims to the department of Haute Marne; and on the bank of a navigable river. It is the seat of a considerable commerce in various articles of agricultural produce or manufacture, which are carried down the Marne to Paris. A considerable number of waxes are made here, and sent to other places in the department. A great part of the wool grown in the department is brought to market at Châlons, and sent from there to Reims, Sedan, Metz, Nancy, and other manufacturing towns: much of the grain expressed from grain is sent to Paris, Reims and Lyon. Leather, cutlery, and some woven fabrics are manufactured.

Among the literary and scientific institutions are a high-school; a botanic garden, with which is connected a course of instruction in botany, given gratuitously; a museum of natural history; a public library of 20,000 volumes; and two seminaries for the instruction of the priesthood. But the most important establishment is the *École des Arts et Métiers*, or School of Arts and Trades, at which the central government and several of the departments maintain fully or in part a number of boarders: those supported by the government are stated by M. Balbi to amount to 450. There is also a flourishing society of agriculture, commerce, and arts. Among the eminent natives of this town mentioned the astronomer Lacaille.

Châlons is the seat of a bishopric which includes the department of Marne, except the arrondissement of Reims, and has a population of 216,396. The bishop is suffragan of the Archbishop of Reims. The diocese was established in the fourth century. Châlons is the capital of a second military division, comprehending the departments of Marne and Ardennes.

The arrondissement of Châlons contained in 1832 a population of 302,000.

lation of 48,000. (D'Anville) alte Brun; Balbi; Emilly; Richard's *Hook*.)

CHALONS-SUR-SAÛNE is the capital of an arrondissement in the department of Saône et Loire. It is the most populous place in that department. It is about 185 miles in a straight line S.E. or S.E. by S. from Paris, or 208 miles by the road through Melun, Sens, Auxerre and Autun. It is in 46° 46' N. lat., and 4° 52' E. long.

This city belonged to the *Ædui* at a period anterior to the Roman conquest of Gaul. In the great revolt under Vercingetorix, many Romans who were here were obliged to quit the place, and many were slain in the assaults which they had to sustain after their departure from the insurgent populace. (*Cibis. de Bel. Gal.* vii. 42.) The name it bore was *Cabillonum* according to Cæsar; other modes of writing it were *Cabillonum* and *Cabillonum*. Strabo has *Καβιλλωνον*, and Ptolemy *Καβαλλωνον*. Ammianus Marcellinus, who wrote about the period of the downfall of the Roman empire, mentions it as one of the ornaments of the province (*Gallia Lugdunensis Prima*) to which it belonged, and gives to its name the form *Cabillones*. From the singular form of the ancient name, it was usual for a long time to write the modern name without an *s*, *Chalon*, by which, when D'Anville wrote, it was distinguished from the town described above. It is now however usually written *Châlons*. In the middle ages the town was much smaller than at present; but a new wall having been built, the suburbs of St. André, St. Marie, and St. Jean de Maisel were included. There is one suburb (of St. Laurent) situated on an island off the *Reine*; this is united with the town, which is on the right bank, by a stone bridge. This suburb contains an hospital remarkable for its internal arrangements and the excellent state in which it is kept.

The town is situated in a fertile country, surrounded by meadows, forests, and vineyards. It is well built; and from the quay there is a fine view. The public walk along the Canal du Centre is adorned with a large obelisk. There are two other public walks, one in the Island of St. Laurent, behind the hospital, the other extending along the river.

Châlons had, in 1832, a population of 12,220. It has been since the revolution a place of considerable trade, for which its situation on the banks of the Saône, close to where the Canal du Centre (which unites the Loire and the Saône) enters that river, and on the high road from Paris to Lyon and the south of France, admirably qualifies it. Among its manufactures are silk stockings, hats, hosiery, and *essence d'Orient*, a preparation of the scales of the bleak, used in the making of mock pearls. The inhabitants trade in corn, wine, leather, oil and soap; this town has a *collège* or high school, a library, an agricultural society and a theatre.

Châlons was formerly the seat of a bishopric and the capital of a district called from it Le Châlonnois. The arrondissement of Châlons had, in 1832, a population of 120,461.

CHALOSSE, a district of Gascogne, watered by the rivers Adour, Midouze, Gabas, and Luy. It is a sandy district, yet producing grain, wine, and fruits, and affording considerable pasturage to cattle. Chalosse was bounded on the N. by the Bazadois, on the S. by Béarn, on the E. by Armagnac, and on the W. by the Pays des Landes. It was subdivided into the territory of Marsan and Chalosse Proper, of which St. Sever was the capital; the territory of Marsan was the smaller of the two, but more productive for its extent. This division of Gascogne is not noticed in the map of 'France in Provinces,' published by the Society for the Diffusion of Useful Knowledge, though the subordinate district of Marsan is. In some old maps the territory of Chalosse Proper is called Gascogne, as though that name were in strict propriety limited to this district; to Marsan they give the name of Albret.

CHALUS, a small town in France on the river Tardoire and on the road between Limoges and Périgueux. Its population (given by the 'Dict. Universel de la France,' Paris, 1844, our latest authority, at 1,356) would be too small to merit a separate notice, but for the historical interest attached to it.

Guidomar, Viscount of Limoges, had refused to deliver to Richard, Count de Lion, king of England and feudal lord of several of the finest provinces of France, a treasure which he had found. Richard consequently attacked the viscount, and laid siege to the castle of Chalus which belonged to him. He refused to the garrison, who were to surrender, an armistice, but that their lives should be saved; and while recon-

g the castle, in order to show the point of attack, he was wounded in the shoulder by an arrow, by Bertrand de Gaudin, one of the English. He lived for about ten days, and then died. He was buried in the church of St. Martin. The death, and the garb of the king, except of Bertrand who was rescued, were all made dreadful. The bold demeanour of this man, who, when brought before the dying monarch, avowed and gloried in his crime, excited the admiration of Richard, who pardoned him. He was, however, put to death, after Richard, expired, by Marchades, commander of the Brabançons, or mercenaries in the service of Richard, by Philippe Augustus of France. (Sismondi, *Hist. des Français*.)

CHALYBÆUS (Zoology), a genus of birds described by Cuvier from the *Cassians* of Buffon. *Paradisæus* of Cuvier. The bill has the same form as that of the *Cassians*, but it is a little larger at the base than that organ is in the last-named genus, and the nostrils are pierced in a large, membranous space.

Geographical distribution.—The known species come from New Guinea, and are remarkable for the metallic tints of their plumage.

Example. *Chalybæus paradisæus*. This richly-plumed bird is the *Paradisæa viridis* of Gmelin; *Le Calybe de la Nouvelle Guinée* of Buffon; *Le grand Chalybe* of Le Vaillant; *Oiseau de Paradis vert* of Sonnerat; *Paradisæa chalybea*, Blue-green paradise bird of Latham; *Cracticus chalybeus* of Vieillot; *Barita viridis* of the first edition of the *Règne Animal* (where it was placed under the *Cassians*, *Barita*), and *Chalybæus paradisæus* of the last edition. It is the *Mansinème* of the Papuan tongue, according to Lesson, who thus writes on the subject from personal observation. 'Among the numerous skins of birds of paradise which the inhabitants of New Guinea brought daily on board, I found some *Chalybæi* deprived of their feet, and run through with a stick like the skins of the true birds of paradise. Afterwards we often procured in our shooting parties a bird which does not vary from that of which we speak, except in having a more sombre and tarnished plumage, there being no difference in the proportions of the body, bill, wings or tail. We regard it as a slight variety of the *Calybe* of authors; for those that we saw, which were adult and in complete plumage, did not permit us to think that they could be *Chalybæi* before or after their moult. The total length of our *Chalybæus* was four-

[*Chalybæus paradisæus*.]

teen inches six lines (French). The bill differed not at all from the ordinary *Chalybæus*. The head is large, and the tail, six inches in length, is rounded by the disposition of the feathers, as in the preceding. The plumage is

bluish metallic, and violet li are and there on it were the brill reflections and neck are short, close set and velvety. The nostrils are partially covered by a membrane covered by the frontal feathers which advance on each side of the edge (arête) of the bill, which is black. The iris is coral-red, and the legs are covered with scales (écussons), and their toes are strong, furnished with raised claws, flattened above, and crooked.

The *Chalybeatus* lives solitary in the forests of New Guinea. We often saw it perched in the great trees, where it seeks for fruits. Its manners appeared to have great analogy to those of the crows.

CHALYBEATE SPRINGS. Of all mineral waters, those containing iron are the most common; but such only are considered chalybeates, in a medical sense, in which the iron predominates, if not in quantity, at least in action, over the other ingredients. The quantity and combinations of the iron vary in every spring; but it is generally combined with carbonic acid, in the form of protoxide or proto-carbonate, and is deposited in considerable quantity in the form of oxide, when the water reaches the external air. The presence of chalybeate springs may generally be detected by the appearance of the stream or water-course. The inky or styptic taste of the water also indicates the presence of iron. In other instances it is combined with sulphuric acid, in the form of sulphate of iron: it is often associated with alumina; and more rarely hydrochloric acid is combined with it. When a large proportion of free carbonic acid is present, such springs are termed *acidulo-chalybeates*.

The temperature rarely exceeds that of the ordinary temperature of spring water, and it is generally lower. Of the former class several exist on the Continent; Bath is the only example in Britain. Cold chalybeate waters, with proper conveniences for their employment, are not very numerous in Britain. Tunbridge, Harrowgate, and Holywell, in England and Wales; and Hartfell, Peterhead, Dunblane, and Bonnington, near Edinburgh, are the chief. Chalybeate waters may be employed either internally or externally in the form of baths; the former mode is the most common in this country. The use of chalybeate waters possesses many advantages over the other modes of administering iron; and not only enables many to employ the metal, but likewise to persevere with it for a much longer time. This is more particularly the case when much free carbonic acid exists in the water, as in the acidulo-chalybeate springs. The cold temperature of the water certainly disagrees with many persons, but this may be obviated, either by beginning with the Bath waters, or pouring the quantity intended to be used into a little warm water, or adding a tea-spoonful of the compound tincture of cardamoms to the first glass. The persons who require chalybeate waters are those who need tonics to improve their constitution and remove a tendency to disease; or convalescents from acute diseases; or persons who have been debilitated either by a residence in warm climates or by severe mental exertions. Persons of a plethoric habit can rarely use them without undergoing some preparatory treatment. Like iron, they are improper during pregnancy, or the course of any inflammatory disease, or the existence of organic affections of the heart or liver, or tendency to apoplexy. When alone, or still more when combined with alumina, they often cause constipation, which requires to be obviated; in some individuals, especially at the commencement of their use, the opposite state occurs: in either case a black colour of the motions is observed, which should excite no alarm, as it simply arises from the tannin of the food uniting with the iron, and forming a black tannate of iron. During the use of chalybeate waters, the diet of the patient requires careful regulation.

The acidulo and carbonated chalybeate waters do not bear transportation well; the waters which contain sulphate of iron may be sent to a distance with less injury to their qualities. Two methods have been proposed to prevent the decomposition of the carbonous and chalybeate waters during removal to a distance: the one by boiling the corks pre-

locks putting them into the bottles; and by merely driving an iron nail through the cork so as to be in contact with the water, which latter method is even said to increase the quantity of iron held in solution by the water.

Baths of chalybeate water are sometimes used along with the internal employment of the water, sometimes alone. They afford great assistance in the cure of diseases for which iron is proper, and can sometimes be employed when the internal use of iron is impracticable. Those of this country are less resorted to than Alexistad in the Harz, or those of Nassau. See *Bubbles from the Brunnen of Nassau*. [IRON. BATHING.] Gairdner on *Mineral and Thermal Springs*.

CHAMA. [CHAMACEA.]

CHAMA'CEA or **CHAMIDÆ**, a family of conchiferous mollusks, the third of the accephalous or headless testacea, according to Cuvier, who places them between his *Mytilacea* (mussel-like testaceans), and his *Cardiacea* (cockle-like testaceans).

Under the Linnæan genus *Chama*, many heterogeneous forms were assembled; and as G. Sowerby observes, 'in his arrangement regular and equivalent shells are placed with such as are irregular and equivalent; free shells with others that are attached to marine bodies; and shells which have two distinct muscular impressions with others which have only one.'

* Bruguière first divided this genus, and Lamarck carried out the reformation. The latter makes the *Chamida* to consist of the genera *Diceras*, *Chama* and *Etheria*, placing *Tridacna* and *Hippopus* under his *Tridacnæ*, the first section of his second order *Conchiferous monomphala*.

Cuvier made the *Camacæ* consist of the genera *Chama*, *Tridacna*, *Hippopus*, *Chama*, (Brug.) *Diceras*, and *Iso-cardia*.

De Blainville arranged under the family *Chama*, *Diceras*, *Etheria*, *Tridacna* (including *Hippopus*), *Iso-cardia*, or as he writes it *Iso-cardium*, and *Trigonia*; giving, however, his opinion that *Etheria* is more properly placed under the family of *Margaritacea*, than under the *Chamacea*; and observing that, according to what M. Deshayes had told him concerning the pallial impression indicating the disposition of the lobes of the mantle, there could be no longer any doubt of this.

Rang, in his 'Tableau Méthodique,' arranges the following genera under the *Camacæ*: *Etheria*, *Chama*, *Diceras*, *Caprina*,—a genus which he conceives to have been confounded with *Diceras*,—*Iso-cardia*, *Tridacna*, and *Hippopus*.

Deshayes, in his Note to his edition of Lamarck, observes, that many observations may be made upon this family, composed, according to Lamarck, of three genera. He says, 'we think it ought to undergo some sufficiently important modifications. Thus in comparing the young *Diceras* with the *Chama*, there is no difference worthy of note; but it must be added, that in proportion as the shells of *Diceras* increase in age, the characters of the hinge become more and more exaggerated, without such an alteration as renders them entirely dissimilar to what they were in their youth. It may be said then, in reality, that the *Diceras* are only *Chamae* exaggerated in their volume, their thickness, the prominence of their umbones (crochets), and the size of their cardinal teeth. There would not then be any inconvenience in uniting the two genera, forming for each of them a section which would have thus less value than a genus established for each.' With regard to *Etheria*, we quite agree with M. Deshayes (who quotes M. Rang's description of the soft parts in the 'Annales du Muséum,' as confirming his (Deshayes's) previous views) in coming to the conclusion that it is necessary to separate the *Etheria* from the *Chamacea* or *Chamida*, which will then consist only of the genera *Chama* and *Diceras*, if, indeed, the latter should be considered as having the rank of a genus.

GENERA.

Chama. The valves are irregular, inclining for the part to the orbicular shape, unequal, generally forspined externally, and adherent. The umbones are distant, unequal, and curled or involute. The hinge consists of one thick, oblique, somewhat notched tooth, inserted into the groove of the opposite valve. There are two muscular impressions, and they are distant and lateral. The ligament is external, and divided into two portions at its anterior extremity. For the soft parts Poli should be consulted. The (*Perilopus* of Poli) is less irregular than the shell,

and cordiform or heart-shaped; the two lobes of the mantle unite posteriorly, and in the commissure are two very small ciliated suckers, like those of *Isocardia*. Upon the abdominal mass a small cylindrical truncated bent foot rises. The mouth is small, and is furnished on each side with a pair of somewhat square and obliquely truncated palpi. Deshayes states that all the individuals of the same species adhere by the valve of the same side, and that the umbones curve in the same direction.

Broderip, in the 1st vol. of the 'Transactions of the Zoological Society of London,' p. 301, (1834) where he describes several new species brought home by Mr. Cuming, says, 'the shells are attached by their external surface to submarine bodies, such as corals, rocks, and shells, and have been observed at depths ranging from points near the surface to seventeen fathoms. These shells appear to be subject to every change of shape, and often of colour, that the accidents of their position may bring upon them. Their shape is usually determined by the body to which they are fixed; the development of the foliated laminae which form their general characteristic is affected by their situation; and their colour most probably by the food, and by their greater or less exposure to light. The *Chama* that has lived in deep and placid water will generally be found with its foliations in the highest state of luxuriance; while those of the individual that has borne the buffeting of a comparatively shallow and turbulent sea, will be poor and stunted. Lamarck has divided the species into two sections: viz., first, those the umbones of whose shells turn from left to right; secondly, those whose umbones turn from right to left. Sander Rang in his Manual, has adopted this division, to which I cannot subscribe, because it will not bear the test of examination. Two remarkable instances are now well known of regular bivalves of the same species, in which one specimen may be regarded as being the reverse of the other, viz. *Lucina Childreni*, and an inequivalve *Mytilus* in the British Museum: and to come at once to the case before us, the same species of *Chama* is sometimes attached by the right, sometimes by the left valve; or, in other words, in one individual of the species the umbones will turn from left to right, while in another individual they will turn from right to left.' The same author observes, that the distinction of the species appears to him to be difficult, the variety being infinite. The number of recent species given in Deshayes's edition of Lamarck (1835) is seventeen, including *Chama nitida* (*Camostree* of De Roissy; *Cleidotherus* of Stutchbury). Broderip, in the paper above alluded to, describes eleven additional species with varieties not noticed by Deshayes, who has however some observations on the following species, *Chama Lazarus*, *gryphoides*, *unicornis*, *asperella*, (the living analogue of *Ch. echinulata* in Lamarck's fossil list.) and *albida*, well worthy the attention of the student. We select as an example *Chama gryphoides*.

[*Chama gryphoides*.]

Local distribution. Apparently confined to the seas, the Mediterranean being the locality of the warmest temperature where any of the species have been hitherto found.

FOSSIL CRAMIDÆ.

We have already seen the approximation, not to say identity, between *Chama* and *Diceras*. It may however be as

• And so has De Blainville

entirely distinct.

Chama.—the Supracretaceous beds, and those of the group; and also in the Sowerby they are found in the *grossier*, also in the chalk and graptolite tables (vol. iii. of Lyell, 1833), g and twenty fossil (tertiary), occurring in the Eocene, and Eocene periods. Of these *Ch. gryphoides*, *crenulata*, *simulans*, both living and fossil, the localities, exception of *crenulata*, from the Tertiary sea. The species found in more than one tertiary formation he makes *Ch. echinulata*, *rustica*, and *lamellosa*, and gives the following number of species in the localities here mentioned:—Four in Sicily, four in Italy (subapennine beds), one at Bordeaux, three at Dax, three in Touraine, two at Vienna, two at Angers, nine at Paris, one at London, and two at Valognes. In the fossil list of his edition of Lamarck (1835), Deshayes enumerates only thirteen fossil species, and of these he makes *Chama gryphina* include *Chama sinistrorsa* as a synonym, observing, in a note that he knows the living analogue as existing in the Sicilian seas, and that the species No. 3 (*Chama lucerna*) is a variety of this, while the valves cited as belonging to the environs of Angers belong to another species. *Ch. echinulata* he identifies with *Ch. asperella* now living in the Mediterranean. *Ch. unicornaria*, he observes, was formed for a variety of *Ch. gryphina*, with very large umbones, and he suggests the necessity of uniting *Ch. gryphina*, *lacinata*, and *unicornaria* in one species. Nilsson names *Ch. cornu Arietis*, (*Diceras arietina*?) Kjøge; Morby, Sweden; and *Ch. lacinata*, Kjøge; Balsberg; Morby, Sweden; and Mantell, an undetermined species from the chalk, Sussex. Phillips names *Chama mima*, or *Gryphina mima* (the genera are sufficiently different, by the way), from the coral oolite and calc. grits of Yorkshire. Smith, *Chama? crassa* from the Bradford clay. Thurman, *Ch. Bernajurensis* from the calc. grit, Bernese Jura; and Lonsdale, an undetermined species from the forest marble, cornbrash, and Bradford clay, Wilts. None of these appear to be noticed by Deshayes in his last edition of Lamarck.

Diceras.—In addition to the supposed identity of *Diceras* with *Chama*, already alluded to, Cuvier says that the *Diceras* do not appear to differ from the *Chama* in any thing essential; only their cardinal tooth is very thick, and the spirals (umbones) of their valves are sufficiently projecting to remind the observer of two horns. G. B. Sowerby writes: 'On account of the similarity between this genus (*Chama*) and *Diceras* we shall be expected to explain the characters by which this latter is distinguished from *Chama*, with which indeed it is arranged by Bruguière; these, according to Lamarck, are the large, conical, diverging, spiral umbones, and the large, concave, subauriculate, prominent tooth in the large valve of *Diceras*. Not having ourselves seen the hinge of *Diceras*, we will not venture to offer an opinion; but, judging from the specimens we possess, we see in *Diceras* a sort of connecting link between *Isocardia* and *Chama*, having both the umbones large and involute, and being, moreover, a nearly oval shell, like *Isocardia*; but being attached by one valve, and not quite equivalve; in these respects resembling *Chama*. Rang observes: 'This genus is very imperfectly known without doubt, but nevertheless one may well believe that it is very near to *Chama*.' DeFrance enumerates five species. Deshayes does not give it as a genus in his tables, and in his last edition of Lamarck only two species are recorded,

[*Diceras arietina*.]

Diceras arietina (Lam.) the type from Mont Salève, and the neighbouring mountains of the Alps, and *Diceras arietina* (Desh.) from the same vicinity of the last named place.

Rang would place the genus *Caprina* of D'Orbigny's series on these interesting shells, the genus would be generally adopted. The genus *Ichthyosarcelite*, which has always been classed with the cephalopods, might, he thinks, belong to a bivalve approximating *Caprina*. Deshayes, he says, communicated to him the same idea. But the author does not notice the genus when treating of *Diceras* in the last edition of Lamarck.

CHAMÆDOREA, a genus of palms, also called *Nunnezharia* and *Nunnezia*. They are small reed-like plants, with ringed shoots. Their leaves are either cleft or pinnated. The inflorescence is sessile within the sheaths of the leaves, and branched in an irregular manner; the spathes are membranous. The flowers are yellow and dioecious, without bracts, which is a remarkable circumstance. In the males the calyx is cup-shaped and three-parted; the petals three, and the stamens six. In the females the calyx and petals are the same; the ovary three-celled; the berry one-seeded; the albumen even; and the embryo lateral. These are palms of humble growth, receding in that respect from the general character of the order, and approximating to herbaceous *Eudogens*, or to Bamboos. *Ch. fragrans*, the Chutassium of the Peruvians, is a plant with a stem about a man's height, and so fragrant as to fill the groves with its perfume in the months of August, September, and October.

CHAMÆPELIA. [DOVES.]

CHAMÆROPS, a genus of palm trees, in which is comprehended the most northern species of those remarkable vegetable productions whose home is so frequently in the tropics. It is characterized by its flabelliform leaves, polygamous flowers, which are sometimes even dioecious, and triple monospermous drupes, with ruminated albumen. *Chamærops humilis*, the European species, grows in hot-houses to the height of fifteen feet; but in Spain and Barbary it is not more than four or five feet high, and in Italy it is much dwarfer. It is common upon the hills near Algiers; it occurs in many places in the southern parts of Italy; and reaches its northern limits in the vicinity of Nice. The trunk of this plant is five or six inches in diameter, and closely covered with triangular hard scales, which are the bases of the ancient leaves. The new leaves grow in a tuft at the top of the stem, and have smooth flat stalks, with rigid spines proceeding from the edge; the blade is deeply palmate, with from twelve to fifteen narrow sword-shaped divisions, which are slightly glaucous and downy. The flowers grow within compressed spathes, which are downy at the edge, and from six to eight inches long, and compressed spadix, which is closely covered. The cupes are blackish-brown, and round, with a fleshy flesh. The young underground parts of the young roots, are said by Desfontaines to

[Chamædorea.]

1. *C. pauciflora*; 2. *C. fragrans*.

CHAMÆLEDON PROCUMBENS, a beautiful little alpine bush, formerly referred to *Azalea*, from which it differs essentially both in habit and botanical characters. It is a small evergreen creeping shrub, found on the mountains of Europe and North America. The leaves are leathery, shining, turned back at their edge, and about half an inch long. The flowers are minute, and grow in terminal umbels of a light flesh colour. The calyx is five-parted; the corolla campanulate and regularly five-cleft, the anthers rounded and opening longitudinally. It is occasionally seen in gardens, but it is rather impatient of cultivation.

CHAMÆLEON, a constellation near the North Pole, first proposed by Bayer. [Bayer.] The stars are as follows:—

[Chamærops humilis.]

CHAMESAURA. [CHALCIDES. CHLOTES. SEPS.]

CHAMÆZA (Zoology), a genus of the family *Moridae*. Vigors. [MERULINÆ.]

CHAMBER, a recess formed at the lower extremity of the bore of a gun, howitzer, or mortar, and in the direction of the axis, in order to receive the charge of powder by which the shot or shell is to be projected. It is made of a cylindrical, hemispherical, or parabolical form, and its magnitude is such as to allow it to contain the quantity of powder constituting the charge, but its diameter is less than that of the bore, in order that the fired gunpowder may act more intensely upon the projectile in the line of its direction.

The *Gomer chamber*, so called from the name of the inventor, is made in the form of a frustum of a cone, terminating with a concave hemisphere at the smaller part, which is the extremity of the chamber, and the greater circumference coinciding with that of the bore. The shot or shell, being placed in close contact with the conical part of a chamber of this kind, thus becomes subject to the whole force of the elastic fluid.

From some recent experiments, it appears that the parabolical chamber is preferable to the other kinds; and if we suppose that the inflammation of the powder were to commence at the focus, the superiority of effect might be conceived to be owing to that property of this curve by which the rays from the focus, after striking the surface, are reflected in lines parallel to the axis.

CHAMBER, IMPERIAL. [IMPERIAL CHAMBER.]

CHAMBERLAIN, *custos cubiculī*, or *subcubicularius*, keeper of the chamber, was an officer of great antiquity, and occurs among many of the earliest nations. In those of the East, as appears from the description of persons employed, chamberlain and eunuch were often synonymous. In the Anglo-Saxon times, in England, the chamberlain appears to have had the name of *Camerarius*, and had the keeping of the king's treasure (Balred, *in vit. S. Edu. Confess.*, c. ii. p. 9), by which name this officer also occurs in the *Domesday Survey*.

The office of lord great chamberlain of England was one of the highest dignity, and was held in grand serjeanty from the second year of King Henry I. by the family of De Vere, from whom it passed, by a female heir, to the family of Bertie. By the statute of precedency, 31 Hen. VIII., the great chamberlain's place was next to that of the lord privy seal. In 1714, the Marquess of Lindsay, then hereditary great chamberlain of England, having been raised to the dukedom of Ancaster, surrendered this precedency for himself and his heirs, except only when he or they should be in the actual execution of the duties of the said office, in attending the person of the king or queen, or introducing a peer into the House of Lords. This surrender was confirmed by Stat. 1, Geo. I. c. 3. The duties which now devolve upon the great chamberlain are, the dressing and attending on the king at his coronation; the care of the antient Palace of Westminster; the provision of furniture for the Houses of Parliament, and for Westminster Hall, when used on great occasions; and attendance upon peers at their creation, and upon other occasions when they perform their homage. On the death of Robert, the last duke of Ancaster but one, in 1779, the office of hereditary great chamberlain descended to his two sisters, Priscilla Lady Willoughby de Eresby, and Georgiana Charlotte Marchioness Cholmondeley, by whom Sir Peter Burrell, the husband of Lady Willoughby (afterwards Lord Gwydir), was first appointed to perform the duties; and subsequently, in 1821, his son the present Lord Gwydir, who still holds the office of deputy great chamberlain of England.

The office of lord chamberlain of the king's household is one which is held during his majesty's pleasure only; and the holder of it is usually changed with the administration. He has the control of all parts of the household, which are not under the direction of the lord steward, the groom of the stole, or the master of the horse; the king's chaplains, physicians, surgeons, &c., as well the royal tradesmen, are by his appointment; the companies of actors at the royal theatre, part of the household, are under his regulation, and is also the licenser of plays.

CHAMBERS, EPHRAIM, was born at Kendal in the latter part of the seventeenth century. His father was a small freeholder in Westmoreland, in respectable circumstances. Ephraim, his eldest son, was bound apprentice to a mechanical trade in London. Eventually he became apprentice to Mr. Senex, the globe-maker; and it was while in his shop that he conceived the design of the *Cyclopædia* which has chiefly preserved his name. Some of the articles

are said to have been written while he stood behind the counter. Before the completion of his work, however, and probably after his death, he was associated with the bookseller who published the *Encyclopædia*, and took chambers in Gray Inn. The first edition of his *Cyclopædia* appeared in 1728, fol. in 4 vols., and was very favourably received. It was published by subscription, the price of each copy being four guineas. Immediately after, the author was made a Fellow of the Royal Society. A second edition of the work appeared in 1788, and a third in 1789. Mr. Chambers was also one of the writers in the 'Literary Magazine,' an analytical review of new works, which was begun in 1735, and continued for some years. He was likewise associated with Mr. ... he botanical professor at Cambridge, in its editing, and abridging the 'Philosophical History and Maxims of the Royal Academy of Sciences at Paris,' which appeared in 1745, 8vo. in 1742. This task he executed very ill. The only other literary work which has been attributed to him is a translation from the French of a quarto volume, entitled 'The Jesuit's Perspective.' He lived to the last the life of a recluse and a hard student, reading and writing from morning to night almost without intermission. A person who was his amanuensis for six years is said to have related that he transcribed for him, and took down from his dictation, in that space of time, not less than twenty large folio volumes, containing as much matter as, if it had been printed, would have made thirty such volumes as those of his *Cyclopædia*. He died on the 18th May, 1740, at Canonbury House, Islington, and was buried in Westminster Abbey, under a short Latin inscription of his own composition. A fourth edition of his *Cyclopædia* appeared in 1741, and a fifth in 1746. To the sixth edition, which was brought out in 1750, were added two supplementary volumes, which were compiled by Sir John Hill, the botanist, and George Lewis Scott, the mathematician. Those, along with much new matter, were incorporated with the original work in the seventh edition, which began to be published in numbers under the superintendence of the late Dr. Abraham Rees, in 1778, and was completed in four vols. folio, in 1785. Chambers's work is also avowedly the basis of the greatly more extended *Cyclopædia* in the conduct of which Dr. Rees afterwards engaged, and which he lived to complete in forty-five vols. 4to. (London, 1802-1819). Indeed it may be said to have originated all the modern *Cyclopædias*, both in the English and in other European languages. It was early translated both into French and Italian. In the prospectus of the great French *Encyclopédie* of Diderot and D'Alembert (afterwards incorporated in the *Discours Préliminaire*), it is admitted that Chambers's plan is excellent, though the execution of the work is very indifferent. The writer adds, that it possibly never would have appeared at all, if there had not previously existed in the French language works from which Chambers drew, without measure and without choice, the greatest part of the matter which composed his dictionary.

CHAMBERS, SIR WILLIAM, is said to have derive his descent from a Scotch family of the name of Chah who were barons of Tartan in France. He was born however in 1726, at Stockholm, in Sweden; whether his grandfather, an eminent merchant, had procured some time before, to prosecute certain claims he had against the government of that country. At two years of age he was brought to England, and put to school at Ripon in Yorkshire. We next read of his making a voyage to China as supercargo, in the service of the Swedish East India Company. This must have been when he was a very young man, for at the age of eighteen he is said to have settled in London, and taken up the profession of an architect and draughtsman. In these capacities, having no formidable rivalry to encounter, he soon obtained considerable reputation. At length he was introduced to the earl of Bute, and by his influence appointed drawing-master to the young Prince of Wales, afterwards George III. Soon after the accession of that king, he was employed to lay out the royal gardens at Kew. In this task he displayed without restraint that predilection for the Chinese style, both of gardening and architecture, of which he had already given intimation in a work, entitled 'Designs for Chinese Buildings,' published in 1769. In 1765 he published in a large folio volume, 'Plans, Elevations, Sections, and Perspectives, Views of the Gardens and Buildings at Kew, in Surrey.' Meanwhile he had also, by a villa in the Italian style, which he erected at Richmond

for the Earl of Beborough, and by various other persons, obtained much reputation and employment as an architect. In 1741] was appointed by the Swedish order of the Polar Star. In 1743 he published this 'Dissertation on Oriental Gardening,' which was a vindication of Chinese tastes and fashions, and it is probable as having exposed the author to the attack of the poet Mason; to the first part of which 'English Garden,' published immediately before, it was supposed to be intended as a sort of answer and confutation. The piece in which Mason took his revenge (if indeed he was the author, which he never acknowledged) was the 'Heroic Epistle to Sir William Chambers, General of his Majesty's Works,' a satire on Oriental Gardening; and a further enrichment with elaborate

production appeared in 1773, and was followed in 1774 by a short continuation, under the title of 'An Heroic Postscript.' The satire, however, does not seem to have injured its object in any essential respect. In 1775 Sir William was appointed to superintend the rebuilding of Somerset House, which is his best work. In 1791 he published his 'Treatise on Civil Architecture,' of which two new editions, one by Joseph Gwilt, F.S.A., the other by an anonymous editor, appeared in 1824. Each contains considerable additions to the original work. Sir William died on the 8th of March, 1796, leaving a large fortune. As an architect, although his taste was fantastic, he frequently showed considerable ingenuity, and also displayed a certain grandeur in his designs. His staircases in particular used to be much admired. In the time of Sir W. Chambers, pure Greek architecture was only beginning to be known in England, and its introduction was at first not much favoured. The recent indiscriminate adoption of Greek models for public buildings in London has filled the metropolis with structures totally unsuited in external form to improve the appearance of a large city, and often ill adapted in their internal arrangements to the purposes for which they are designed. Instead of large masses and lofty buildings, the streets of London are crowded with mean porticoes and pigmy pillars, attached to edifices of so little elevation, and so much cut up into small parts, as to lose by comparison with many of the adjoining houses. The street-front of Somerset House is in all respects better adapted to a great city than the Greek models which are now generally adopted. After Somerset House, among Chambers's most successful efforts, are the mansion which he built for the marquis of Abercorn at Duddingstone, near Edinburgh, and, Milton Abbey in Dorsetshire, which he built in the Gothic style for Lord Dorchester.

CHAMBERY, the capital of the province called Savoy Proper, is the most considerable town in all Savoy, and the residence of the military governor of that Duchy, and of the senate or high court of justice for all its provinces. [Savoy.] It lies, at an elevation of 930 ft. above the sea, in a fine valley, between two ridges which run N.W. and S.E., from the Rhone to the Isère, and may be considered as lower off-sets of the Alps. The valley is watered by the river Leisse

which falls into the pretty lake of Bourget, eight miles N.W. of Chambery. The valley from Bourget to Montmélian is eighteen miles long and three broad. It abounds with grass, and the lower part is rich in pastures, but is subject to sudden inundations from the swelling of the mountain streams. The climate is mild, being sheltered from the N. winds. Chambery has a royal college, kept by the Jesuits; an academy of sciences, called the Academy of Savoy, which publishes its memoirs; a society of agriculture and commerce; a public library, with a cabinet of natural history; and a school of drawing. There are many hospitals, houses for refuge, and other charitable institutions; several of which were founded by a native, General de Boigne, who after an adventurous career in India in the last century, returned home with a large fortune, of which he devoted several millions of francs to improve his native city. He died a few years ago at his residence of Buisson Rond, near Chambery. The churches of Chambery have some good paintings. The population of the town and suburbs is about 11,000. (*Calendario Sardo*.) Many families of the nobility of Savoy, some of them very ancient, reside in this town. The people of Chambery speak remarkably good French, but the country people have a patois which is a dialect of the Romance language. Provisions are cheap, which is generally the case in Savoy, where incomes are very moderate. Many beggars, especially of the class of country people, are seen in the streets of Chambery. Amadeus V. was the first duke of Savoy who established his residence here. This town has produced many distinguished men, among others, the Abbé de St. Réal, Vaugelas, Albanis Beaumont, known for his travels in the Alps; the painters Berenger and Berger; and the two Counts de Maistre, Xavier and Joseph, well-known in contemporary literature. (Bertolotti, *Viaggio in Savoia*.)

CHAMBORD. [LOIR ET CHER.]

CHAMECK. [ATKINS, Species 8.]

CHAMELEON, CHAMELEON-TRIBE; CHAMELEONIDÆ (Zoology), the name for a well-defined family of Saurians (lizard-like reptiles), whose differential and essential characters may be summed up as existing in the form of their feet, the toes of which are joined or bound up together in two packets or bundles opposed to each other in their shagreen-like skin—in their prehensile tail—and in their extensile and retractile vermiform tongue.

Organization, Skeleton.—The more striking peculiarities consist in the elevated and pyramidal form of the *scaput*, the absence of a true *sternum*, and in certain apophyses of the vertebral column, especially about the tail, where they are placed *en chevron*, so as to leave at their base a space where the caudal artery, a prolongation of the pelvic, is protected somewhat in the same way as the spinal chord is by the bony case above it, when the prehensile tail would otherwise subject it to pressure in grasping boughs of trees or other solid bodies with its lower surface. The transverse apophyses of the tail are but little developed. The glenoid cavity is supported upon a short pedicle. The majority of saurians have eight cervical vertebrae, but the chameleons,

[Skeleton of Chameleons]

There is not much difference between the *oesophagus* and stomach, which latter is wider and bent back upon itself. There is no true *pylorus*, although there exists, the point, where it should be, a sort of constriction in the intestine, which there thickened.

Organs of Sense.—The under surface of the tail and toes are granulated papillae, probably for the purpose of conveying to the *sensorium* the force of the body grasped. The tongue must have a considerable share of the sense of *touch*; whether it has any high perception of that of *taste* may be doubted. *Smell*.—Most probably not acute; the external orifices of the nostrils are more lateral, and consequently wider apart than in most of the other saurians. *Hearing*.—There is no visible external ear, but an internal cavity not much developed in the bones of the sides of the skull, communicating with the throat, and covered externally by the common integument. *Sight*.—The eyes of the chameleon are remarkable objects projecting, and almost entirely covered with the slagreen-like skin, with the exception of a small aperture opposite to the pupil: their motions are completely independent of each other. It adds to the strange and grotesque appearance of this creature, to see it roll one of its eye-globes backwards, while the other is directed forwards, as if making two distinct surveys at one time. Its sight must be acute, from the unerring certainty with which it marks and seizes its prey.

Reproduction.—By means of eggs, which are numerous at each deposit, oval, and enveloped in a white, tough, parchment-like skin.

Hoids, &c.—The chameleons spend their lives in trees, for clinging to the branches of which their organization is admirably adapted. There they lie in wait for the insects which may come within their reach; and it is highly probable that, in such situations, their faculty of changing their colour becomes highly important in aiding them to conceal themselves. Of this faculty, concerning which so much has been written and said, we shall presently say. The powers of abstinence possessed by this singular race are very great, and hence most probably arose the old fable of their living on air, which was for a long time considered to be the chameleon's dish. We kept one for upwards of six weeks, and during all that time it never, as far as we could observe, took any sustenance, though meal-worms, and other insects were procured for it. Notwithstanding this fast, it did not appear to fall away much. It would fix itself by the feet and tail to the bars of the sander and there remain motionless, apparently enjoying the warmth of the fire for hours together. Its motions were excessively slow. It was a female, and died after laying a great number of eggs. Hasselquist describes one, that he kept for nearly a month, as climbing up and down the bars of its cage in a very lively manner.

That the chameleon was known to the ancients is no doubt. It was the *χαμαιλέων* of the Greeks and the *chamaeleon* of the Latins. Aristotle's history of the animal proves the acute observation of that great zoologist, for he notices the peculiarities of the animal, the absence of a sternum, the disposition of the ribs, the mechanism of the tail, the motion of the eyes, the toes bound up in opposable bundles, &c. &c., though he is not entirely correct in some points. (*Hist. Anim.*, book 2, ch. xi.) Pliny (*Hist. Nat.*, lib. viii., c. 33) mentions it, but his account is for the most part a compilation from Aristotle.

part a compilation from Aristotle.—
Power of changing colour.—Passing by the earlier statements of those who have written on the subject, we shall commence with the details of modern times. First, in his ‘Zoography,’ gives the following translation of the account given by the French academicians of this phenomenon: ‘The colour of all the eminences of our chameleon when it was at rest, in the shade, and had continued a long time undisturbed, was a bluish grey, except under the feet, where it was white inclining to yellow; and the intervals between the granules of the skin were of a pale and yellowish red.’—‘The grey, which coloured all the parts exposed to the sun, changed when in the sun; and all the places of the skin which were illuminated, instead of their bluish colour, came of a brownish grey, inclining to *minime*. The rest of the skin which was not illuminated by the sun changed its grey into several black and shining colours, forming spots about half a finger’s breadth, reaching from the crest of the spine to the middle of the back; others from the sides of the ribs, fore legs, and tail. All these spots were of a *Isabella*

[Skull of *Chamaeleo* ~~sp.~~ *buddus*.]

Organs of respiration.—Cuvier observes that their lung is so large that, when it is filled with air, it imparts a transparency to the body, which made the ancients say that it lived upon air, and he inclined to think that to its size the chameleon owed the property of changing its colour; but with regard to this last speculation he was in error, as we shall presently see.

Organs of nutrition and digestion.—The teeth, as in the great majority of saurians, have no true roots: their crowns, which are trilobed*, seem to be soldered as it were upon the edge of the upper border of a groove hollowed in the maxillary bone; they are connected to the osseous portion and also to each other, so as to present the appearance of an enamelled and denticulated portion of the edge of the bone. But it is the vermiform extensile and retractile tongue which is the chief organ for taking the insects on which the chameleon lives. By a curious mechanism, of which the *os hyoides* (tongue-bone) is a principal agent, the chameleon can protrude this cylindrical tongue, which is terminated by a dilated and somewhat tubular tip covered with a viscid secretion, from the sheath at the lower part of the mouth, where the whole of the tongue, with the exception of the dilated tip, remains when at rest, to the length of six inches. When the chameleon is about to seize an insect it rolls round its extraordinary eyeballs so as to bring them to bear on the devoted object: as soon as it arrives within range of the tongue that organ is projected with unerring precision and returns into the mouth with the prey adhering to the viscous tip. Some writers speak of the wonderful celerity with which this feat is performed, and it certainly forms a strong contrast to the other almost ridiculously slow motions of the animal. We have never seen chameleons take a fly, but we have often seen them catch meal-worms; and the operation, though comparatively rapid, was not remarkable for its quickness, but done with an air of deliberation, and so that the projection and retraction of the tongue could be very distinctly followed with the eye.

[Chameleon taking his prey.]

* But see post, p. 475.

colour, through the mixture of a pale yellow with granules were present, and a bright red, which is of the bottom of the skin, which is visible between the scales; the rest of the skin is lightened by the which was of a darker grey than ordinary, resembled a clot made of mixed granules, some of the granules being greenish, others of a mixture of grey, and others of the usual bluish grey, the ground remaining as before. When the sun did not shine, the first grey appeared again by little and little, and spread itself all over the body, except under the feet, which continued of the same colour, but a little browner; and when, being in this state, some of the company handled it, there immediately appeared on its shoulders and fore legs several very small spots, about the size of a finger nail, and which did not take when it was handled by those who usually took care of it. Sometimes it was marked with brown spots, which inclined towards green. We afterwards wrapped it up in a linen cloth, where having been two or three minutes, we took it out whitish; but not so white as that of which Aldrovandus speaks, which was not to be distinguished from the linen on which it was laid. Ours, which had only changed its ordinary grey into a pale one, after having kept this colour some time, lost it insensibly. This experiment made us question the truth of the chameleons taking all colours but white, as Theophrastus and Plutarch report; for ours seemed to have such a disposition to retain this colour, that it grew pale every night, and when dead it had more white than any other colour; nor did we find that it changed colour all over the body as Aristotle reports; for when it takes other colours than grey, and disguises itself to appear in masquerade, as Elian pleasantly says, it covers only certain parts of the body with them. Lastly, to conclude the experiments relative to the colours which the chameleon can take, it was laid on substances of various colours and wrapped up therein; but it took no other as it had done the white, and it took that only the first time the experiment was made, though it was repeated several times on different days. In making these experiments, we observed that there were a great many places of its skin which grew brown, but very little at a time: to be certain of which, we marked with small specks of ink those granules which to us appeared whitest in its pale state, and we always found that when it grew brownest and its skin spotted, those grains which we had marked were always less brown than the rest.

The details of this experiment should be borne in mind when reading the interesting memoir of Mr. Edwards, to which the reader is afterwards referred.

Hueter thought that the changes of colour depended on a kind of disease, more especially a sort of jaundice to which the animal was subject, particularly when it was put in a cage.

Mrs. Obsonville thought that he had discovered the secret in the blood. He considered that the change of colour depended upon a mixture of blue and yellow, whence the different shades of green were derived, and these colours he obtains from the blood and the blood-vessels. Thus he says that the blood is of a violet blue, and will retain its colour on linen or paper for some minutes if previously steeped in a solution of alum, and that the coats of the vessels are yellow both in their trunks and branches; consequently, he argues, the mixture of the two will produce green. He further traces the change of colour to the passions of the animal. When, he observes, a healthy chameleon is provoked, the circulation is accelerated, the vessels that are spread over the skin are distended, and a superficial blue green colour is produced. When, on the contrary, the animal is imprisoned, impoverished, and deprived of free air, the circulation becomes languid, the vessels are not filled, the colour of their coats prevails, and the chameleon changes to a yellowish green, which lasts during its confinement.

Barrow (*African Travels*) declares, that previously to the chameleon's assuming a change of colour, it makes a long inflation, the body swelling out to twice its usual size, and when this inflation subsides, the change of colour gradually takes place; the only permanent marks being two small dark lines passing along the sides. Mr. Wood conceives from this account, that the animal is principally indebted for these varied tints to the influence of oxygen.

Mr. Spall also regards these changes as connected with the state of the lungs; and Mr. Houston considers this phenomenon as dependent on the turgescency of the skin.

Not to go farther into the numerous treatises and memoirs

which have been published on this intricate subject, without giving a just conclusion, we refer to the conclusions of the able and interesting paper of Mr. Milne Edwards, for whose lucidness the solution of this puzzling phenomenon was reserved. It appeared in the 'Annales des Sciences Naturelles' for January, 1834, and is translated in the seventeenth volume of the 'Edinburgh New Philosophical Journal,' p. 313. The steps by which he first overthrew the received theories on the subject, and then arrived at a knowledge of the cause of the change of colour, are so clearly stated, that we recommend our readers to study the whole memoir, the results of which only we give here.

1. That the change in the colour of chameleons does not depend essentially either on the more or less considerable swelling of their bodies, or the changes which might hence result to the condition of their blood or circulation; nor does it depend on the greater or less distance which may exist between the several cutaneous tubercles; although it is not to be denied that these circumstances probably exercise some influence upon the phenomenon.

2. That there exists in the skin of these animals two layers of membranous pigment, placed the one above the other, but disposed in such a way as to appear simultaneously under the cuticle, and sometimes in such a manner that the one may hide the other.

3. That every thing remarkable in the changes of colour that manifest themselves in the chameleon may be explained by the appearance of the pigment of the deeper layer to an extent more or less considerable, in the midst of the pigment of the superficial layer; or from its disappearance beneath this layer.

4. That these displacements of the deeper pigment do in reality occur; and it is a probable consequence that the chameleon's colour changes during life, and may continue to change even after death.

5. That there exists a close analogy between the mechanism by the help of which the changes of colour appear to take place in these reptiles, and that which determines the successive appearance and disappearance of coloured spots in the mantles of several of the cephalopods.

Geographical distribution. Warm climates of the old world, South of Spain, Africa, East Indies, Isles of Sechelles, Bourbon, France, Moluccas, Madagascar (where it is said that there are seven of the species which belong to Africa), Fernando Po, and New South Wales.

Species. The family consists but of one genus, *Chamaeleo*, but there are several species. We select *Chamaeleo vulgaris* as an example. Localities, Africa and India, Egypt, Barbary and South of Spain, Cuvier. Central Africa, Col. Denham. India, Gen. Hardwicke. Tripoli, Mr. Ritchie. Egypt, Geoffroy.

See General Hardwicke's and Mr. Gray's paper on the saurian reptiles of India in the Zoological Journal, vol. iii, p. 231, where it is observed that the teeth are rarely (as they are described to be by Cuvier) slightly three-lobed. When the animal is alive and in health, the angles of the occipital pyramid and the lines on the side of the face are completely obliterated. It is distinguished from a species from Central Africa, by the occipital keel extending to the centre of the eye, by the back of the head being only slightly lobed, and by the frontal scales being tubercular.

[*Chamaeleo vulgaris.*]

natic arrangement. Most zoologists seem to consider the *Chamaeleonidae* as an isolated family. Linnaeus places the Chameleon—he seems to have been aware of but one species—in his extensive genus *Lacerta*, under

which and *Draca*, he arranged all the saurians known him. *Oppe! (1811) placed the chameleons in his third family, the *Iguanoides*. Merrem (1820) formed for them his fifth tribe, the *Prendentia*. De Blainville (1822) arrai them among his *Agamoides Andromaux*. Latreille (1 made them the fourth and last family immediately following his *Gekotians* of his second order of scaly reptiles, the *Lacertiformes* (lizard-shaped). Mr. Gray, who has contributed some new species, divided (1825, 1831) the saurians, properly so called, into five families of two sections replacing the *Chamaeleontidae* as the last family of the second, next to the *Lacertinidae*. Fitzinger (1826) arranges them under his second tribe, *Squammati*, of which they are the second family between the *Gekkos* or *Ascalabotoides*, and the *Pneustoides*. Cuvier (1829, 2nd vol. of last edition of *Règne Animal*) arranges them as his fifth family of saurians between the *Gekkos* and the *Shincks*. Wagler (1830) places them as the first subdivision, the *Acrorhines*, of his fourth tribe, *Thecoglossi**, of his third order, *The Lizards*. Wiegmann (1834) who, as well as Wagler, makes the structure of the tongue an important element in his classification of this branch, arranges them in the second series, *Rhiphoglossi*† of his second sub-order *Squammati*. Duméril and Bibron, in the arrangement proposed by them (1835), consider the chameleons and the gekkos as two groups absolutely anomalous, and name the former *Cameleontiens* or *Chélopodes*, the latter name being derived from the supposed resemblance of their claws to those of piners.

Those who would wish to go further into the history and structure of this extraordinary family may consult the works of the following authors, in addition to those above alluded to:—Geener, Perrault, Daudin, Laurenti, Lacépède, Brongniart, Vallinot, Tiedemann, Vander Hoeven, Bruyn, Frenzel, Goddard, Hopfer, Hussem, Kaulund, Kirchner, Major, Meyer, Oken, Parsons, Voigt.

CHAMOIS. [ANTELOPE, Group xiv. Species 48.]

CHAMOMILE. [ANTHEMIS.]

CHAMONDE ST., a town in the department of Loire in France, on the bank of the little river Gier, a tributary of the Rhône, and on the road between the great manufacturing towns of Lyon and St. Etienne, 25 or 26 miles from Lyon and about 7 from St. Etienne: it is in 45° 1' N. lat. and 4° 30' E. long.

The population of St. Chamond in 1832 was 7475; the inhabitants are employed in various branches of the silk manufacture, especially in making ribands and laces, of which there are more than thirty manufactories. In the suburb of St. Julien are some considerable iron works. The town has a handsome church, a place or square surrounded by trees, forming a promenade, and baths. In the environs are some vestiges of Roman antiquities. In the neighbourhood there are extensive coal-pits, and quarries of stone for building.

CHAMOUNY, or CHAMONIX, an Alpine valley in Savoy, at the foot of Mont Blanc. It runs north-east and south-west, being in length about thirteen miles, and about two in breadth: it is watered by the Arve, which has its source in the Col de Balme, at the north-east extremity of the valley. The Arve is joined in the middle of the valley by the Arveron, which issues out of the glacier of Montanvert. The valley is bounded to the east and south-east by the great chain of the Pennine Alps, which divides this part of Savoy from the Val d'Aosta in Piedmont, forming a succession of lofty peaks, called Aiguilles (Needles), covered with perpetual snow, and known by the names of Aiguilles de Tour, Argentière, Verte, Dru, Aiguille du Midi, and lastly Mont Blanc, which rears itself high above the rest, at the south-west extremity of the valley. The clefts between these different mountains are the receptacles of extensive glaciers, which slope down to the very edge of the fields of the valley of Chamouny. The principal one, called La Mer de Glace, spreads itself between two parallel masses of the great chain, formed by the Géant and Jorasse on one side, and the Dru, Montanvert, Charmoz, and Aiguille du Midi on the other. The length of this icy sea is about six miles, and its greatest breadth about two miles. A branch of it slopes down through an opening between the Dru and the Montanvert towards the valley of Chamouny. On the west side, the valley of Chamouny is bounded by the Brevent, 8000 feet high, which is an offset of the group of the Buet, the sum-

mit of which is covered with perpetual snow, and which divides the valley of the Arve from that of the

good mountain, and extends across the Arve, which there is a magnificent view of the great with all its mountains and glaciers, as well as of the

the group of the Buet the northern part of the other mountains the interior of Savoy. Other without ascending to the summit of the Brevent, content themselves with riding on mules up a steep zigzag to the Croix de la Flegère, a station on the side of the mountain, from which the view of the opposite chain is also remarkably good. The view from the bottom of the valley itself is too confined (the mountains rising abruptly like walls all about it) to give a true idea of the extent and height of that mass of Alps. The Montanvert is ascended on mules, and the sea of ice may be reached, but the latter part of the excursion is not without some risk, on account of the numerous crevices in the ice, which are of unfathomable depth; strangers who venture on the glaciers should trust implicitly to their guides. Some adventurous travellers, and two English ladies among the rest, have of late years crossed the sea of ice, and then ascending the Col du Géant, 10,000 feet, descended to Cormayeur, in the Val d'Aosta.

The road from Geneva to Chamouny follows the course of the Arve by Bonneville, Cluses, St. Martin, Chablais, and Servoz. The approach to the valley of Chamouny from St. Martin is nearly as interesting as the valley itself. The cascade and little lake of Chede, and the scenery about Servoz, are remarkably fine. Travellers put up at the Prieuré, which is the principal village in the valley of Chamouny, and contains two very good inns, where one meets with numerous company from all parts of Europe. Each party of travellers engage a guide, with mules; the pay of a guide is fixed at six francs a day, and as much for each mule. The guides are generally very civil and trustworthy; they are all tried men, and are licensed by the local authorities. From Chamouny one may, without retracing his steps back to Geneva, proceed to Martigny, on the high road from Geneva to the Simplon, practicable for mules lead to Martigny; the most direct is over the Col de Balme, 2000 feet above the sea, into the valley of Trient, in the Valais. The other path leads through the secluded valley called Valorsine; and then over La Tête Noire, likewise to Trient. From Trient the path leads over the mountain called La Forclaz, from which there is a fine view of the lower Valais and the opposite chain of Alps in the Oberland, and then to Martigny. The journey from Chamouny to Martigny is easily made in one day.

Besides Le Prieuré, which derives its name from a former Convent of Benedictines, founded in 1099, the valley of Chamouny has several other villages or hamlets, such as La Tour, Argentière, Les Prés, Bossons, Ouches, &c. The whole valley contains about 2700 inhabitants, and is divided into four parishes. (*Calendario Sardo*, 1825.) It produces some barley and oats, but the chief property of the inhabitants consists in cattle; very good honey is also got here. From one to two thousand strangers visit this valley every summer, and their expenditure forms an important addition to the income of the natives. At the Prieuré are collections of minerals, crystals, amethysts, topazes, and other fine stones, which are found in the mountains. The village of the Prieuré is, according to Saussure, 3346 feet above the sea, so that the perpendicular height of Mont Blanc above the level of the valley is 12,386 feet, an elevation greater than that of the Chimborazo and other summits of the Andes above the plains immediately below them. One may however to the vast buttresses which Mont Blanc throws out towards the valley of Chamouny, its height does not strike so much on this side as on its south or Italian side, towards the narrow valley called Allée Blanche and Val d'Entrèves, where it rises more abruptly, and in a single mass. A path branching out of the road from Geneva to Chamouny, and passing by St. Gervais and Contamin, over the Col de la Seigne, 8000 feet above the sea, leads by the Allée Blanche and the Val d'Entrèves to Cormayeur in the Val d'Aosta; but the excursion is laborious and without danger, except in the very middle of summer and in very fine weather.

The valley of Chamouny was not frequented by travellers till about the middle of the last century, when Saussure, Deluc, and above all Bourrit, made its beauties known, as well as its advantages as a station from which to explore the group of Mont Blanc. In one respect the valley of

* Having the tongue in a sheath.
† Having a projectile or protractile tongue.

Chamouny is inferior to the Alpine valleys of the Bernese Oberland; other parts of central Switzerland has no waterfalls, but there is stillness in its scenery adds to its imposing effect.

CHAMP, a king of Amber, the East Indies by M. de la Roche.

CHAMP DE MARS [Paris.]

CHAMPAGNE, one of the provinces of France, important from its extent and interesting from the former greatness of its feudal lords. It was bounded on the N. by Luxembourg and Namur, districts of the Low Countries; on the E. by the Breton and other parts of Lorraine; on the S.E. by Franche Comté; on the S. by Bourgogne; on the S.W. by the Gers; its district partly included in Orléanais and partly in Berry (France); on the W. and N.W. by Brie Française and other parts of the Isle of France, and by Picardie. Its greatest length from N. by W. to S. by E. was nearly 200 miles; its greatest breadth, nearly at right angles to the above, about 150 miles. It was subdivided into eight districts, viz.: Rethelois in the N., including the towns of Rethel, population 6585; and Mézières, 3737; and extending to Givet and Charlemont, 4093. Brie Champenoise, including Meaux, 8481; and Provins, 5665, on the W.; Senonois, including Sens, 9267; Joigny, 4700; and Troyes, 3773; on the S.: Bassigny, including Chaumont, 8104; and Langres, 5960; on the S.E.: Vallage, including Joinville, 415; and Pertuis, including Virey Le François, 6976; and Sainte Menehould 2933; on the E.: and Champagne Proper, including Epervray, 5318; Châlons 12,413; and Troyes 23,749; and Reims, including Reims, 3597, in the centre. The population of the above towns is from the census of 1832, except that of Sainte Menehould, which is from that of 1826.

The greater part of Champagne is comprehended in the basin of the Seine, by which, and by its tributaries, the Marne, the Aube, and the Yonne, it is watered. To these rivers we may add the Aisne (a feeder of the Oise), with its tributaries the Sappe and the Vèle, the Armançon, and the Seine, feeders of the Yonne; and the Meuse, which waters the north-eastern and northern parts. The Seine, Aube, Marne, Aisne, Yonne, and Meuse are navigable.

Champagne, as its name implies, is a flat country; the elevations are few and inconsiderable. The soil varies considerably; part of it is barren, producing only oats, rye, and buckwheat, and of these but inferior crops: Yet on the whole, the crops of grain in the departments into which Champagne has been divided (Aisne, Ardennes, Aube, Marne, Haute Marne, and Yonne), exceed considerably the average produce of France; and the wines of Champagne enjoy the highest reputation. Wood abounds in some places, while in others the inhabitants experience great scarcity of fuel and of other building materials. Other parts abound with pools. The whole country may be considered as well stocked with poultry, game, and fish. There is considerable pasturage, and the number of horses and sheep in the departments above mentioned exceeds the average of the departments in France. For further information to the soil, productions, &c., of Champagne the reader is referred to the accounts of the departments already named.

History of Champagne. At the period of Cesar's invasion of Gaul, the country, afterwards known as Champagne, was divided between the two great races of the Celts or Galli properly so called, and the Belgæ; the Matrona, or Marne, was their common boundary. Of the Belgic tribes the most important, especially after their early-formed and faithfully-kept alliance with the Romans had secured to them the patronage of that powerful people. The Catalauni (supposing such a people really to have existed) [CHALONS SUR MARNE] were probably a subdivision of the Sami. These tribes gave name to Reims and Châlons. Of the Celtic race were the Senones, the Tricasses, and the Lingones who have given name to the towns of Sens, Troyes, and Langres. It is not clear to us whether the Sami, who inhabited the eastern part of the province, were Celtic or Belgic race.

In the division of Gaul by the Roman emperors this district was divided between the provinces of Lugdunensis Prima and Quarta (or Senonia), and Belgica Prima and Secunda. The boundaries of the Roman provinces called Lugdunensis, Belgica, and Belgica, are not to be regarded as quite identical with the boundaries of the Celtic and Belgic races.

Champagne was one of the parts of Gaul which remained longest in the possession of the Roman emperors. After the Burgundians and Franks had crossed the Rhine and secured settlements in that country, and the south and west parts had been occupied by the Visigoths, may even after the Roman empire itself had fallen, and the last Caesar of Rome had been overthrown, the person of Augustulus (A.D. 476), Alaric and his son, who governed this part of Gaul in the name of the emperor of the West, continued in possession of the province, and still upheld the Roman name. However, Alaric was defeated by Clovis and Ragnacarius, king of the Franks, and Champagne became a part of the extensive kingdom over which Clovis reigned. After the death of Clovis (A.D. 511) it became part of the kingdom of Austrasia, one of those into which the states acquired and ruled by him were dismembered.

It was probably about this time that the designation of Champagne (in Latin Campania, an open country) was given to the district. We read in the ancient historians of Campania Remensis (from Remi or Reims) Campania Catalaunensis (from Catalauni or Châlons), and Campania Tullensis (from Tullum or Toul), of which the last must have been in Lorraine. It is in the works of Gregory of Tours (an historian of the 6th century) that the name, as we believe, first occurs. We read of several dukes of Champagne during the continuation of the Merovingian dynasty. The last of these were of the family of Pepin l'Hierial, mayor of the palace of Austrasia, one branch of whose posterity shortly after ascended the throne, and are known as the princes of the Carolingian dynasty. The dissensions of this family appear to have brought the ducal dignity to an end before the Carolingians ascended the throne.

Under the Carolingian princes the great officers of the provinces and governors of the towns contrived in many cases to render their power hereditary; their dependents managed to do the same; and even the archbishops and bishops made themselves masters of the towns which were the capitals of their diocese. The archbishops of Reims and Sens obtained the chief power in Champagne. The rise however of the powerful house of Vermandois repressed the ambition of the prelates, obliged them to give up their temporal power, and finally obtained the pre-eminence in Champagne. In the early part of the 10th century Heribert, or Heribert II., count of Vermandois, became, according to Baugier (*Mémoires Historiques de la Province de Champagne*), first sovereign and hereditary count of Champagne and Brie. He appears to have entitled himself count of Troyes and Meaux. He was an active participator in the troubles which marked the reign of Charles le Simple, whom, by an act of treachery, he made his captive. Disgraced by the refusal of a fief which he had asked of Raoul, who succeeded to the throne upon the captivity of Charles, he released the latter; but, shortly afterwards, having come to an accommodation with Raoul, he sent Charles back into confinement, in which he died A.D. 929. The ambition of Heribert involved him in new troubles with Raoul and with Hugues or Hugh, count of Paris and duke of France, the most potent lord of his time, and brother-in-law of Heribert: with this last, however, Heribert formed an alliance against the king Louis IV. Outre Mer, who was continually involved in disputes with the powerful aristocracy of his kingdom. Heribert died A.D. 943.

The death of Heribert seems to have been the signal for hostilities on the part of the king, and of others who had cause of quarrel with the deceased count. Among these was Artaud, archbishop of Reims, whom Heribert had deposed in order to place his son Hugues in the see. We find the rival claimants to the archbishopric engaging actively in these hostilities. The children of Heribert were protected by their uncle Count Hugues of Paris; and two of them were successively counts of Champagne. About 1019 the county of Champagne came, upon the extinction of the male line of Heribert, to Eudes, or Odon, who was by his mother's side great-grandson of Heribert: he inherited of his father the counties of Blois, Tours, and Chartres. It does not appear that these lords of the greater part of Champagne bore as yet any other title than that of Counts of Troyes and Meaux, though their power was such as to enable them to rank among the great lords of France, even before the union of Blois, Tours, and Chartres; and after that union Eudes was able to enter into a contest with the king of France, Henry I., and to struggle with the Emperor Conrad.

the Salic for the succession the kingdom of Burgundy, also aspired to possess self of the crown of Lorraine. These contests were not however successful; and the death of Eudes, who fell in battle November, 1037, fighting against the troops of Cothelon, duke of Lorraine, put a stop to his ambitious designs.

Upon the death of Eudes the county of Blois was separated from Champagne, his inheritance being divided between two of his sons, Etienne and Thibaut; but the death of the former reunited the whole in the hands of Thibaut I., who had inherited Blois, and seized Champagne, to the prejudice of Eudes the son of Etienne, as if to compensate for the loss of the county of Tours, which he had been obliged to cede to the count of Anjou. The death of Thibaut, A.D. 1087, was first who took the title of the Count of Champagne, led to a fresh separation of these possessions, which were however, A.D. 1125, re-united in the person of Thibaut II., count of Blois. The city of Troyes owes much of its importance to the favour of this prince, who established the first manufactures of that city, and distributed the waters of the Seine throughout the place by an immense number of channels, in order to supply the various workshops. He died A.D. 1152. According to some, this prince was the first who was properly count of Champagne.

Henry I., son of Thibaut II., had, during his father's life, accompanied Louis VII. of France to Palestine in the second crusade (A.D. 1147). He visited Palestine a second time as a champion of the cross, A.D. 1178; but his expedition was unfortunate. He was made prisoner in Illyria on his return home, and though released by the Emperor of the East, his health suffered so much from his toils and sufferings that he died seven days after his return to France, A.D. 1181. Meaux owes to him its municipal government. He was count of Champagne, but not of Blois, which his younger brother, Thibaut le Bon, inherited. Henry I. retained the authority of suzerain over the county of Blois.

Henry II., son of Henry I., succeeded his father. In 1190 he set out for the Holy Land, and was present at the great siege of Acre. He served with Richard I. of England, by whose influence he was nominated king of Jerusalem. He died in consequence of falling from a window of his palace at Tyre, A.D. 1197, and was succeeded in the county of Champagne by his brother Thibaut III. The latter swore allegiance to Philippe Auguste, king of France, yet supported Richard of England against that monarch. In 1199 he took the cross, but died A.D. 1200 or 1201 before he could set out with the crusade of which he had been appointed the chief.

Thibaut IV., posthumous son of Thibaut III., possessed the county of Champagne from his birth, A.D. 1201, to his death, A.D. 1253. He was involved in almost perpetual broils with the other great nobles of France. In 1234 he became by inheritance through his mother king of Navarre. In 1239 he went as a crusader to the Holy Land, but the dissensions of the generals caused the failure of the expedition.

Thibaut V., son of the late prince, succeeded to the county of Champagne and kingdom of Navarre, as well as to the hereditary predilection of his family for crusading expeditions. He accompanied St. Louis to Tunis, and died on his way home at Trapani in Sicily, A.D. 1270. Henri III., his brother and successor, died 1274; Jeanne, daughter and heiress of Henri III., married Philippe IV. le Bel, king of France; and by the consequences of this marriage the county of Champagne became united to the crown of France. The marriage took place A.D. 1284, and with it ends the history of this province.

CHAMPAGNE-WINE is the produce of the vineyards of the departments of the Marne, Haute Marne, Ardennes, and Aube, which were comprehended in the ancient province of Champagne. Of the various growths of Champagne, that made on the banks of the Marne has the highest reputation, and forms the greater part of what is sent to foreign countries. Champagne wine is light in body, containing on the average, according to M. Brander, only 12.61 per cent. of alcohol; it is of various colours, white, straw-colour, pink, and red; and these again are divided into sparkling, creaming, and still, or as they are called in France *mousseux*, *crémant*, and *non-mousseux*. The red wines of good quality are, for the most part, exported to Belgium, and the white to England, Russia, Germany, the Levant, Greece, and the French West India colonies; some portion of the shipments to England are re-shipped to India and other parts. Of late years a con-

siderable demand for this wine has arisen in the United States, and if this demand should increase in the same degree at present, it is calculated that in four or five years it will be larger than Great Britain and her colonies. There is a large exportation of Champagne in Paris and the principal cities of France, which is also drunk in the places of production. The population of the department of Champagne, which consumes on the average 23,000 hectolitres in the year, being at the rate of 84 bottles for each person. The wine consumed on the spot is chiefly of the inferior qualities, and so great is the disparity in this respect, that in the same commune the produce of the same vintage (1834) sold at prices varying from 150 francs to 200 francs the hectolitre, while the wine of a neighbouring commune sold for 20 francs the hectolitre—about three francs per bottle: these prices were for new wine.

A great deal of care is required in the management of sparkling and creaming wine. The fermentation in the cask ceases in about three months after the vintage, when the wine must be racked from its lees: a dry cold day is chosen for this operation. In a month from that time a second racking is performed and the wine is fined with isinglass; sometimes a third racking precedes the bottling, which takes place in March or April. It is necessary to use great care in rejecting all bottles which are not strong and of uniform thickness. When the bottles are corked, and the corks secured with packthread, the bottles are placed on the sides in rows piled one above another to the height of six feet. In July or August following, the formation of the carbonic acid gas, to which the effervescence is owing, causes a considerable breakage of the bottles. The loss from this cause varies from 5 to 40 per cent. When the breakage is proceeding most rapidly the workmen wear wire masks in the cellars as a protection from the broken glass, which is projected with considerable force. This breakage continues until the middle of September. In the following month the piles are taken down, the broken bottles taken away, and the sediment which has formed in the whole bottles is removed in the following manner. The bottles are first placed in a sloping position, with the necks downward, and are shaken occasionally without taking them up, in order to detach the sediment from the bottle and to cause it to subside into the neck. When this effect has been produced, each bottle is removed, its sloping position being preserved; the wire and twine are taken off and the cork is withdrawn, when the sediment will be driven on by the carbonic acid gas. Some dexterity is required or the part of the workman to get effectually rid of the sediment without wasting the wine. The bottles are then filled up with bright wine, corked, wired, and binned as before. It is often necessary to repeat this process several times before the wine is sent from the cellar, and it is a general rule with the dealers never to send away wine which has not undergone this operation within a fortnight from the time of its being dispatched.

The time that has been mentioned is that in which the effervescence usually occurs, but it is sometimes delayed to a later period, and even to the following year. When this greater time has elapsed, if symptoms of effervescence are not apparent, the wine is mixed in a cask with some new wine, and treated as before. Still, or non-sparkling wine, is not bottled until the autumn following the year of its vintage.

The losses and expense of labour attending just described add materially to the cost of the wine, so that the price of the first quality delivered from the dealer's cellar is seldom under 3 to 4 francs the bottle; of the second quality 2½ to 3 francs, and the third quality 2 to 2½ francs.

The quantity of land planted with vines in the department of the Marne was stated by the Chamber of Commerce of Rheims, in Sept., 1834, to be 20,600 hectares (acres), yielding 28 to 30 hectolitres (616 to 660 imperial gallons) of wine for each hectare, or about 255 gallons per acre. Owing to superior cultivation the produce of the vine has much increased during the last 40 years, although the quantity of land planted with vines has been lessened. The productiveness of vineyards is subject to great uncertainty. In some years the average quantity is more than doubled, and in others the produce does not amount to one-fourth of an average vintage. In an official statement of the produce of the vineyards in the department of the Aube, the years 1828 to 1833, the average annual produce is given as 530,609 hectolitres, while, in 1828, the quantity reached 1,036,599

hectolitres, and in 1830 was only 135,000 hectolitres. The value of vineyard land in the department of the Marne is very great. It is stated that such spots have been sold as high as 50,000 francs per hectare, or 800*l.* per acre; but this is an extreme price, the usual value of land being from 12,000 to 30,000 francs per hectare (from 200*l.* to 480*l.* per acre). The quantity of sparkling wine sent away from Reims in 1833 is stated by one of the principal merchants of Reims to have amounted to 2,559,000 bottles, which were distributed thus:—England and British India 467,000; Russia 400,000; Germany, including Prussia and the Austrian Dominions, 439,000; United States of America, Canada, and West Indies, 400,000; Poland 100,000; Italy 80,000; Belgium 56,000; Holland 30,000; Denmark 30,000; Switzerland 30,000; Spain 30,000; Spain and Portugal 20,000; Turkey 20,000; and other parts of France 620,000 bottles.

CHAMPAGNE, PHILIPPE DE, was born in Brussels, in 1602. His parents, who were in middling circumstances, indulged his early taste for painting, and he was placed under masters in his native place. At the age of nineteen he went to Paris, with the intention of passing on to Rome, but he was unable to accomplish his journey; probably from the want of means. He received some assistance in his studies from Fontaine, and afterwards became acquainted with Nicholas Poussin, the great painter returned from Italy, from whose advice and society he derived great advantage. They painted in company in the Luxembourg. Upon the death of Duchesne, Champagne succeeded to his place as painter to the queen. Richelieu endeavoured to withdraw him from his royal patronage, but Champagne refused his most brilliant offers. He was indeed so scrupulous in his conduct that he never touched a brush on holidays, nor ever painted from the naked figure. He married the daughter of Duchesne, by whom he had a son. He was received into the academy on its first formation, in 1648, and was subsequently elected its president. He died in 1674.

Champagne laboured with extreme assiduity, and acquired great ability. His drawing is minutely correct, and his colouring is fine; but his design and effect are tame. His portraits are not highly esteemed, particularly one of Richelieu. His principal works are at Paris, where he spent nearly the whole of his life.

Philippe de Champagne, on the death of his wife and son, adopted a nephew, Jean-Baptiste, whom he instructed in painting, but he never attained any distinction.

CHAMPLAIN, a lake of considerable extent situated on the N. boundary of, but almost entirely within, the United States of North America. It derives its name from Samuel de Champlain, a French naval officer, who was governor-general of Canada in the 17th century. It divides, for more than 100 miles, the state of New York from that of Vermont, and its most northern extremity belongs to Lower Canada. It stretches in this direction very nearly from S. to N. from 43° 30' to 45° 4', or through 109 miles. As the boundary between the United States and Lower Canada runs along the parallel of 45°, only about 5 miles of its northern extremity belong to Canada. But the lake may fairly be considered as extending still further north in the narrow channel called the river Chambly, or Sorel, as far as the town of St. Jean, in Lower Canada; this will add about 30 miles more to its length. Its area may be between 600 and 700 square miles. Its breadth varies from about half a mile to 20 miles, and its depth in some places very great. On both sides of the lake are high grounds which rise to a considerable elevation. Owing to this circumstance the numerous rivers which, from the E. as well as from the W., empty themselves into the lake, though they run from 40 to 60 miles, are only navigable at their mouths; the entire fall in their course being from 500 to 1000 feet. The short river, which issues from Lake George and enters Lake Champlain at its southern extremity, is likewise unfit for navigation on account of its rapids and cataracts. Lake George is nearly 200 feet above Lake Champlain, and Lake Champlain only 90 feet above the tide-water in the St. Lawrence. This lake is navigated by vessels of considerable size. It discharges its water by the Chambly or Sorel, which leaves it at its most northern extremity and falls into the St. Lawrence near the town of Sorel, or Henry William. The Chambly is navigable for river-boats, and forms the most frequented line of communication between the United States and Lower Canada. Steam-boats ply

between Whitehall, at the southern extremity of the lake, and St. John. Among the numerous islands of Lake Champlain, the largest are North and South Hero and Lamotte, belonging to the State of Vermont.

The principal towns on or near the lake, are Plattsburgh, St. Albans, Burlington, and Whitehall. In September, 1814, a naval battle was fought on this lake, near Plattsburgh, in which Commodore Macdonough, the American commander, defeated the British fleet. (Darby; Bouchette.)

CHAMPLAIN CANAL, in the state of New York, commences at Whitehall, at the southern extremity of Lake Champlain, and runs in a general southern course to the Hudson at Fort Edward. From Fort Edward it runs southward along the west side of the river, past Watoga, and joins the Erie at Watervliet above Albany. The whole length of the canal, including about several miles of improved river-navigation, is sixty-four miles. By this canal a water communication is opened between the Hudson and the St. Lawrence, through Lake Champlain. It was completed in 1822.

CHAMPOLLION, JEAN FRANÇOIS LE JEUNE, so called to distinguish him from his elder brother, generally called Champollion Figeac, who is the author of several works on ancient history and archaeology, was born at Figeac, in the department du Lot, in 1790. He studied in the lyceum of Grenoble, and afterwards went to Paris in 1807, where he applied himself to the oriental languages under Langlès and De Sacy, but more especially to the study of the Coptic, and to Egyptian archaeology in general. In 1811 he was appointed professor of history in the lyceum of Grenoble, and librarian of the public library. In 1814 he published his first work *L'Egypte sous les Pharaons*, 2 vols., 8vo.; which is a geographical description of that country under its ancient kings, with a view to fix its divisions, the sites and names of its towns, &c. The work is accompanied by a map. In the preface, alluding to the hieroglyphics on the Egyptian monuments, he says, 'that it was to be hoped that from those monuments, on which ancient Egypt painted mere material objects, we should be able at last to discover the sounds of its language, and the expression of its thought.' In 1821 he published at Grenoble a little work, *De l'Ecriture Hiéroglyphique des Anciens Egyptiens*, in which he stated his opinion, 'that the hieratic characters were merely a modification of the hieroglyphic symbols, which was adopted for the sake of brevity, and as a sort of hieroglyphic short-hand, and were not alphabetical characters as it had been supposed by some; the hieratic characters, as well as the hieroglyphic from which they are derived, being expressive of objects and not of sounds.'

In the year following appeared Champollion's letter to M. Dacier, the secretary of the academy of inscriptions and belles lettres, 'relative à l'alphabet des hiéroglyphes phonétiques employé par les Egyptiens pour inscrire sur leurs monuments les titres, les noms, et les surnoms des souverains Grecs et Romains,' Paris, 1822. In this letter he retracted what he had formerly asserted, in so far that he now demonstrated what Dr. Young had already stated in November, 1819, in the supplement to the *Encyclopædia Britannica*, art. 'Egypt,' namely, that the Egyptians used occasionally hieroglyphic signs as alphabetical characters on their monuments, to express the names of foreign sovereigns Greek and Roman, who ruled over their country. In the introduction to his next work, *Précis du Système Hiéroglyphique*, etc., Champollion observes, and his friend Rosellini confirms it in his biography, that he came to the same conclusion as Dr. Young contemporaneously with the latter, and by his own investigation; but this assertion, especially with regard to contemporaneity, is at variance with the statements of the Grenoble work already mentioned, which was published as late as 1821, nearly two years after the publication of Dr. Young's discovery. However this may be, Champollion at least improved upon Dr. Young's hint, and deduced a phonetic alphabet, applicable not only to the names and titles of foreign sovereigns, but also to those of the native sovereigns and of the divinities of ancient Egypt. By comparing Champollion's alphabet with Dr. Young's, the difference between the two is apparent. Champollion used the word *phonétique* to express characters denoting sounds, a term which had been used long before him by Zoëga in the same sense in his work on Obelisks. In his *Précis du Système Hiéroglyphique des Anciens Egyptiens, ou Recherches sur les Éléments premiers de cette Ecriture Sacrée, sur leurs di*

verses combinaisons et sur les rapports de ce système avec les autres Méthodes Graphiques Egyptiennes, Paris, 1824, has asserted, 1. That his phonetic alphabet is applicable to the royal names of the most ancient epochs. 2. That the

in a great measure composed of signs purely alphabetical, and such as are determined in his phonetic alphabet. It seems almost superfluous to remark that the two last positions are mere assertions, unsupported by proof, as any one who will take the pains to examine attentively Champollion's works will easily see. Klaproth, in his 'Observations Critiques sur l'Alphabet Hieroglyphique découvert par M. Champollion le Jeune,' which precedes his 'Collection d'Antiquités Egyptiennes, Paris, 1829, has in our opinion completely demolished Champollion's general theory, and reduced his discovery to its proper limits. Klaproth concludes his critical observations with the following corollaries: 1. That Champollion appears to have had no fixed basis for his system, as he has repeatedly altered the meaning of his characters, both phonetic and symbolic, as appears from comparing the alphabet of the second edition of his 'Précis,' 1827, with that of the first. 2. That although he has explained proper names and some particles of speech, yet he has never been able to read satisfactorily one connected sentence of Hieroglyphic writing, nor three or four consecutive words of the demotic characters of the Rosetta stone. 3. That he assumes against all probability that the Coptic language, which is a mixed dialect, and known to us in a very imperfect state, is the language that was spoken by the Egyptians under the Pharaohs, its sounds, according to him, being represented by the phonetic signs. 4. That it appears that the names of the kings and the ordinary epithets attached to them are written alphabetically in the cartouches or frames; but that besides these, every king has another title of honour or prænomen which fills up another cartouche, and which seems composed partly of alphabetic and partly of symbolic characters, which last have hitherto been only explained by conjecture. Besides these and other general arguments against Champollion's system, for which we refer to Klaproth's work, Klaproth charges Champollion with having completely altered several cartouches of the table of Abydos, to make them suit his hypothesis. And further, he does not forget to remind us that Champollion, while passing through Aix on his way to Egypt in 1828, saw a fine papyrus belonging to Mr. Sallier, written in demotic characters, which he gravely pronounced to be 'a history of the campaigns of Sesostrius Ramses, written in the ninth year of that monarch's reign by his bard and friend.' This assertion was published as a great discovery by the academy of sciences of Aix, and the report was inserted in Ferrussac's 'Bulletin Universel.'

During Champollion's visit to Turin in 1824, to examine the Egyptian Museum of that city, he wrote two letters to the Duke of Blacas d'Aulps, who had become his patron at the French court. In these letters he explains the names and titles of many of the Pharaohs written upon the monuments in the Turin collection, and he undertakes to class them into dynasties, with the assistance of Manethon. ('Lettre à M. le Duc de Blacas d'Aulps, relatives au Musée Royal Egyptien de Turin,' Paris, 1824-5.) His work on the Egyptian gods came out in parts, but has never been completed: 'Pantheon Egyptien, ou Collection des Personnages Mythologiques de l'ancienne Egypte, d'après les Monumens, avec un texte explicatif.' Charles X., having determined to purchase a valuable collection of Egyptian antiquities, just arrived at Leghorn, for the museum at Paris, Champollion was appointed, through the Duke of Blacas, to proceed to Italy for the purpose of examining and valuing them. From Leghorn he proceeded to Rome and Naples, in the company of Rosellini. On his return to Paris, he was named Director of the Egyptian Museum at the Louvre, of which he published a description, 'Notice descriptive des Monumens Egyptiens du Musée Charles X.,' 1827. In 1829 the King of France appointed a scientific expedition to proceed to Egypt, in order to examine the monuments of that country under Champollion's direction. At the same time the Grand Duke of Tuscany, Leopold II., appointed a similar expedition for the same object, at the head of which he placed Rosellini, Champollion's friend. The two expeditions, consisting of six Frenchmen and six

Tuscans, sailed together from Toulon, and arrived at Alexandria in August, 1829. Champollion remained till the end of 1829, during which time he wrote the letters which are published under the title of 'Lettres écrites d'Egypte et de Nubie en 1828-9,' 8vo., Paris, 1833. On his return to France, in 1830, he was made a member of the Institute, and subsequently appointed, by Louis Philippe, Professor of Egyptian Antiquities in the College of France. It was agreed between the French and Tuscan governments that the result of the observations of the two expeditions should be published together in one work, in French and Italian, under the direction of Champollion and Rosellini, 'Monumens de l'Egypte et de la Nubie, considérés par rapport à l'Histoire, la Religion, et les Usages Civils et Domestiques de l'Ancienne Egypte,' &c. The work began to appear in parts, in 1832. In the letters accompanying this publication Rosellini has not only exposed the general system of Champollion, but has carried it much farther than his friend. A sharp criticism upon it by Cataldo Jannelli, was published in No. 19 of the 'Progresso,' a Neapolitan Journal, Naples, 1835. While Champollion was preparing the first part of the new work for the press, he was attacked by a paralytic fit, and died at Paris on the 5th March, 1832.

Champollion's merits, as a laborious student of Egyptian archæology, are undeniable; but his judgment seems not to have been sound, his deductions from his premises not always correct, and his learning (except Egyptian antiquities) neither extensive nor exact. He corrected Dr. Young's first rude notions as to the phonetic symbols, and considerably extended the number of known signs; and this may perhaps lead to further results. Had he lived longer, he might have modified some of his former assertions, and entered perhaps upon a safer path of investigation. For the controversy concerning the general application of the phonetic alphabet, see vol. ii. of the *Egyptian Antiquities* of the British Museum, published in the *Library of Entertaining Knowledge*, ch. x., on the 'Rosetta Stone,' where the subject is fully investigated. See also Professor Kosegarten, *De prisca Aegyptiorum Literatura Commentatio*, 4to., 1828, in which the professor observes that only forty of the demotic or enchorial characters are yet deciphered, which represent five vowels and eleven consonants, while there is a vast number of other signs in the same writing, the value of which is not known, nor is it yet ascertained whether they are phonetic or symbolic; Greppo's *Essay on the Hieroglyphic System of Champollion*, translated by Stuart, Boston, 1830. Rosellini wrote a biographical notice of Champollion in the *Florence Antologia* for April, 1832. Champollion made a Coptic Grammar and Dictionary, which remain yet unpublished.

CHANCE. This word has been used in two senses, as opposed to Providence, and as opposed to Certainty. For the theory of chances, in the latter sense, see *PROBABILITY*, THEORY OF.

CHANCE-MEDLEY, in English law, is a singular corruption of *chaudemellé*, a term well known in old French legal phraseology, and in the barbarous Latin of ancient ordinances translated *calida melleia*. The term in French law denoted, consistently with its etymology, a casual affray or broil, accompanied with violence, but without deliberation or preconceived malice. (Ducange, *Gloss. ad verbum Melleia*.) In English law, it can hardly be doubted that Chance-medley originally meant the same thing; but in modern times the expression is limited to a particular kind of homicide, viz. the killing another in self-defence upon a sudden and unpremeditated encounter. There is often much difficulty in distinguishing homicide by chance-medley, which, though an offence by law, is excusable on the ground of self-defence, from the crime of manslaughter. The general distinction is, that if both parties are actually fighting, he who gives the mortal stroke is guilty of manslaughter; but if one of them at first refuses to fight, and on being closely pressed, retreats as far as he can, and at last, in order to avoid his own destruction, kills his antagonist, this is homicide excusable on the ground of self-defence; or, as it is inaccurately called, chance-medley. See Foster's *Crown Law*, pp. 275, 276, and tit. 1.

CHANCEL. This is rather a term of ordinary use, more than one which would be used by any person who was undertaking to give a scientific description of the several parts of the fabric of a Christian church. As far as we have observed, it is now used to denote that part of a church in which the communion table or altar is placed, and the area before it, in which the congregation assemble when the

Such as administered. Such a church was often separated from the nave or body of the church by lattice work, *cancelli*, and it was from this circumstance that the term *chancel* seems to have originated.

In some churches, however, it may have been the chapel of a particular family. This is the case in which some particular family in a private oratory within the church, which has usually been the burial place of the family. These private chapels or oratories are sometimes called *chancels*, for the same reason that the great choir is sometimes so called; that is, in consequence of being divided from the rest of the church by *cancelli*.

CHANCELLOR (Latin, *Cancellarius*). The primary meaning of the word is 'qui ad cancellos assistit,' one who is stationed near the lattice-work of a window or a doorway, to impede visitors, &c. A cancellarius in this sense was no more than a door-keeper. The emperor Carinus made one cancellarii prefect of the city, a promotion which caused great dissatisfaction. (Vopiscus, *Carinus*.) In another sense, cancellarius was a kind of legal scribe, so called also from his position at the *cancelli* of the courts of law. The cancellarius, under the later emperors, and in the Constantinian court, was a chief scribe or secretary (a *procurator*), who was ultimately invested with judicial powers, and a superintendency over the rest of the officers of the emperor. He was called cancellarius because he sat near the *cancelli* (within the lattice), a screen dividing off a portion of a larger room for the sake of greater privacy; from which circumstance the *chancel* of a church also acquires its name.

The prelates of the Roman church had likewise an officer so called; in the Church of England, each bishop has a chancellor, to whom are entrusted judicial functions. All the modern nations of Europe had a chancellor, though his powers and duties seem to have varied in each.

In England the chancellor was originally the king's chief secretary, to whom petitions were referred, by whom patents and grants from the crown were approved and completed, and by whom reports upon such matters were, if necessary, made to the king; hence he was sometimes styled *Referendarius*. This term occurs in a charter of Ethelbert, A.D. 603; and Selden (*Treatise on the Office of Chancellor*) considers it synonymous with *chancellor*, a name which, he says, first occurs in the history of England, in the time of Edward the Elder, about A.D. 920.

In the capacity of secretary he was the adviser of his master; prepared and made out his mandates, grants, and charters; and finally (when seals came into use) affixed his seal. Hence, perhaps because in early times he was usually an ecclesiastic, he became keeper of the king's conscience, manager of his patents, the officer by whom prerogative writs were prepared, and keeper of the great seal. The last ecclesiastic who exercised the office was John Williams, archbishop of York, who was lord keeper from July 10, 1621, to November 1, 1625; his friend and secretary, John Hacket, who became bishop of Lichfield and Coventry, wrote his life in a volume of singular interest, which he entitled *Sorinia Reserata*.

The special interference of the king, as the fountain of justice, was frequently sought against the decisions of the courts of law, where they worked injustice; and also in matters which were not cognizable in the ordinary courts, or in which, from the maintenance or protection afforded to his adversary, the petitioner was unable to obtain redress. The jurisdiction with which the chancellor is invested had its origin in a portion of discretionary power, which was retained by the king on the establishment of courts of justice (*Legal Jurisdiction in Chancery stated*, p. 27, et seq.). Though the exercise of those powers in modern times is scarcely, if at all, less circumscribed and hemmed in by rule and precedent than the strict jurisdiction of the courts of law [Equity], controversies have at times arisen as to the powers of the chancellor: the particulars of one dispute have been preserved to us entire. (*The Jurisdiction of the Chancellor vindicated*. Printed at the end of 1 and in the 1st vol. of *Collect. Jurid.*)

One of this officer in England is Lord High Chancellor of Great Britain. He takes rank above all dukes not of the blood royal, and next to the archbishop of Canterbury, is appointed by the delivery of the great seal into his hands. There are instances of his having been arrested. The resumption of the great seal by the holder of his office. By virtue of his office he is the

king's principal officer in matters of law, and a privy councillor; speaker and president of the House of Lords, chief judge in the court of chancery, and the head of the judiciary of the law; viz., the king's right of all hospitals and colleges of royal foundation; the patron of all crown livings under the name of a year, according to the valuation made in the reign of Henry VIII. and confirmed in that of Elizabeth. He appoints and removes all justices of the peace, though usually only at the recommendation of lords-lieutenants of counties. He presides over summoning parliaments, and transacts all business connected with the supply and use of the great seal. To him was entrusted the care of infants and their property, until the dissolution of the court of wards and liveries; he has the jurisdiction over idiots and lunatics by special commission from the crown. He also exercises a special jurisdiction conferred upon him by various statutes, as original and appellate judge, as to charitable uses, friendly societies, infant lunatic and idiot trustees, in certain appeals from the court of review, in bankruptcy, and in many other cases. He is a conservator of the peace, and may award precepts and take recognizances to keep the peace; and has concurrent jurisdiction with the other judges of the superior courts, with respect to writs of habeas corpus. Except in the case of service of process, given to him by some recent statutes, the lord chancellor has no jurisdiction in Scotland.

The authority of lord chancellor and lord keeper are made the same by the stat. 6 Eliz. c. 18: though, it is not now customary to appoint a lord keeper. The last lord keeper was Lord Henley, in 1757. The great seal is however sometimes put into commission during the temporary vacancy of the office, or the sickness of the chancellor, the seal being entrusted to the chief commissioner. (1 Will. and M. c. 21.)

The chancellor is not only a judicial officer of the crown, but he has important political functions—he has a seat in the cabinet, and usually takes an active part in public measures. He resigns office with the party to which he is attached. The inconvenience and necessary delay arising from his removal during the pendency of suits in his own court and before the House of Lords, and the arrears of business caused by the variety of duties which he is called upon to perform, have suggested the necessity of some alteration in the constitution of the office. Many expedients have been tried; a vice-chancellor has been appointed; the master of the rolls has been empowered to assist in the usual and ordinary functions of the court of chancery; and a number of useful and important reforms have been made in the subordinate offices of the court. But such is the pressure of business, that all these measures have been ineffectual to remedy the inconvenience; and a bill was introduced into the House of Lords, during the present session (1835), by the chancellor, Lord Cottonham, for the purpose of effecting still further alterations. Upon discussion, it did not appear that the measure was sufficiently matured; though, in all probability, some alteration in the office will be speedily effected.

By the 3 and 4 Wm. IV., c. 111, sec. 3, in consideration that the Chancellor had lost the patronage of certain offices then abolished, the king is empowered to grant an annuity of 5000*l.* a year to the Lord Chancellor or Lord Keeper on his resignation of office. There is also a Lord High Chancellor of Ireland, whose authority within his own jurisdiction is in most respects the same as that of the Lord High Chancellor of Great Britain. (Selden, *Off. Ch.*; Black. *Com.*; Story on *Equity*; and the *Books of Chancery Practice*.)

The *Chancellor of a Church* or of a *Bishop* is Vicar-general to the bishop, holds his courts, and directs and assists him in matters of ecclesiastical law. He has a freehold in his office, and he is not necessarily an ecclesiastic; but if he is a layman, or married, he must be a Doctor of the Civil Law. (Black. *Com.*; 37 H. VIII. c. 17.)

The *Chancellor of a Cathedral* is an officer who superintends the regularity of the religious services.

The *Chancellor of the Duchy of Lancaster* presides either in person or by deputy in the court of the Duchy of Lancaster concerning all matters of equity relating to lands holden of the king in right of the Duchy of Lancaster. The court is holden in Westminster Hall, and was formerly much used; at present it is rarely employed.

The *Chancellors of the Universities of Oxford and Cambridge* are elected by the respective corporate bodies of which they are heads; they exercise exclusive jurisdiction in all civil actions and suits where a member of the University

privileged person is one of the parties, except in cases where the right to freehold is concerned. In both the English Universities the duties of the Chancellor are in nearly all cases discharged by a Vice-Chancellor.

The *Chancellor of the Exchequer* is under-treasurer, and holds the seal of the Exchequer. The office of Lord High Treasurer is now executed by the Lords Commissioners of the Treasury. The Chancellor of the Exchequer is the principal finance minister of the crown; the office is generally held by the Prime Minister when he is a member of the House of Commons. The legal functions of the Chancellor of the Exchequer are now merely formal. Bills in the Exchequer are addressed to him, and to the barons of that court, and on some occasions (as on his appointment) he sits in court; but all the legal business is transacted by the barons. If the chief baron and barons are equally divided in opinion, the Chancellor of the Exchequer may be required to re-hear the cause with the barons, and give his decision. The last instance occurred in 1735, when Sir Robert Walpole gave his decision upon a question of considerable doubt and difficulty, which is said to have given great satisfaction. (Bl. Com.; Fowler's *Exchequer Practice*.)

The *Chancellor of the Order of the Garter* and other orders of knighthood seals and authenticates the formal instruments of the chapter, and keeps the register of the order. He exercises various functions at the installation of the knights, and during their meetings and processions.

CHANCELLOR OF SCOTLAND. As in England, the chancellor of Scotland was always a high officer of the crown, and had great influence with the king and authority in his councils. As in England too, that authority at length extended itself beyond its former limits, and affected the whole judicial power of the kingdom. Its operation and effect in the two countries, however, was different: for while in England the chancellor only carved out for himself a jurisdiction in equity, in Scotland he reached the head of the administration of justice, and sat in a court which dispensed both equity and common law, and the course of proceeding in which all the other judicatures of the realm were bound to follow.

In 1425, which was shortly after the return of King James I. from his long captivity in England, the 'chancellor and with him certain discrete persones of the three estates chosen and depute by the king' were erected into the court of the session, for the final determination of all matters competent to the king and his council. The court of the session however expired with Bishop Wardlaw, from whom in all likelihood it originated; the chancellor's office being taken, on his death, from his protégé, Bishop Cameron, and given to Sir William Crichton, a layman, when the former policy of determining suits by the old common law was restored. This continued (with the exception of an attempt to the contrary in 1457, probably under the influence of Bishop Shoreswood, the favourite and confessor of King James II.) till the time of Bishop Elphinstone, to whom undoubtedly may be ascribed the crafty arts passed in 1487 for the recovery of the large jurisdiction of the chancellor and court of the session, as well as the act 1491, c. 5, to enforce in the courts the study and practice of the canon and civil laws. Nor perhaps shall we greatly err in considering his zeal to have been employed in establishing in 1503 the court of daily council, which was essentially a restoration of the old court of the session. But all these proved only preparatory steps to the erection of the court of council and session, or college of justice, which was instituted in 1532, and has continued to our own time. Of this college the chancellor, or, as he then began to be styled, lord chancellor of Scotland, was to be principal; and as on the one hand it was the supreme court of the kingdom, and on the other all inferior courts were required to copy its proceedings, it wielded the whole judicative power of the country. It early claimed, also, and exercised, a large legislative power under the statutes permitting it to pass acts of sederunt; and the officers who executed its warrants and decrees were either its own messengers or else messengers, over whom it obtained complete control. These powers the court wielded so as to effect nearly an entire change of the law. The ecclesiastical estate for some time predominated both on the bench and at the bar. The consequence was, the canon and civil laws became, what indeed they used to be styled, the common law of the land, and the old common law became obsolete and antiquated. Much of this has been corrected since the Reformation; and still more since the

union with England, where old common law has ever continued the antagonist of the Reformation the authority of long afterwards made statute from being either of the canon law was in the main essentially broken by the Union, when both portions of the island became one great mercantile community, while the civil law was in many respects unsuitable; and since that event various provisions have been made to improve and assimilate the laws and practices of the two kingdoms.

The similarity of procedure in the court of session in Scotland and the high court of chancery in England is striking. Both courts indeed, and the ecclesiastical courts of both countries, borrowed their forms from the court of Rome, and with these last the forms of the court of session in many respects still agree. The bill, or written supplication to the court for letters, whether of summons or of diligence, is of the same nature with the supplication for letters in the court of Rome; and it is observed that when the desire of the bill is granted, it is in the same terms in both courts. The concordance and answers are plainly derived from the *articuli* and *responsiones* of the papal tribunal. The *initialia* testimony, or *purgatio* of a witness, are identical with the *interrogatoria generalia* of that court. Letters of advocacy, suspension, and interdiction, are well known there. The '*malis appellatum et bene processum*' is but verbally translated in the phrase of the Scots court, 'finds the letters orderly proceeded'; and letters of homing, caption, and relaxation, bear their papal origin impressed upon them. It appears also that from an early period the court issued commissions to its officers to perform judicial duties, as the ecclesiastics appoint the inferior church officers their legates and commissaries for the like purposes; and at an early time also the judges began the yet subsisting custom of changing their name on their elevation to the bench, in imitation, as it seems, of the like custom on elevation in the papal hierarchy.

From what is above stated, we may see why there is no court of chancery in Scotland; separate from the courts of common law, as in England; the whole judicatures of Scotland having become subject to the court of session, where the chancellor presided, dispensing both equity and common law. From the earliest times there was an office of chancery in Scotland, and we shall find that many of the early chancellors had been '*clerici cancellarii*'.

A list of the chancellors as of the great officers of the crown in early times, is of considerable importance, particularly in settling the dates of early charters. The series of chancellors given in Crawford's '*Officers of State*' is very imperfect; and in the subsequent list of Chalmers (*Calad*) there are also various errors and deficiencies. A more correct list than any we have yet met with is therefore subjoined. In Beaton's '*Political Index*' there is a chancellor so early as the reign of Malcolm III., but the more authentic series begins with

- Constantine, earl of Fife, who is C. temp. Alex. I.
- Herbert, abbot of Selkirk, temp. Alex. I. and Dav. I.
- Edward, temp. Dav. I.
- John, bishop of Glasgow.
- William Cumyn, previously clerk to Chancellor Godfrey of England, 1133—1142.
- Jordan, *clericus regis*, 1142—3.
- Edward, 1143.
- Walter is said by Chalmers to have been C. from 1146 to 1160, but he is in office about the year 1144. (Hol. Col., vol. i. p. 38; Dugdale, *Monast.*, vol. i. p. 486.)
- Patrick, Bishop of Brechin, was C. temp. Dav. I., and that see was founded circa 1150.
- Ingelram, archdeacon of Glasgow, is said by Chalmers to have been C. from 1160 to 1164; but he was in office in 1151, and was continued by King Malcolm. (Keith's *Bishops*.)
- Walter is again C., 7 Malc. IV.
- Edward, 1163 (Keith's *Bishops*, edit. Russel, p. 1163).
- Nicolaus, *cler. regis*, 1165—1171.
- Walter de Bidun, *cler. regis*, 1171—1178.
- Roger, 1178—1189.
- Hugh de Roxburgh, archdeacon of St. Andrews, 1189—1199.
- William de Malvoisine, bishop of Glasgow, (Keith's *Bishops*.)
- Florence, made C. according to Chalmers in 1200, ac-

according to Crawford in 1202, and according to Keith in 1208.

William de Boscho, bishop of Dunblane, 1211.

Thomas de Strivelin, archdeacon of Glasgow, 1226—7.

Matthew Scot, archdeacon of St. Andrews, 1227.

William de Lincay, 1231.

William de Bodington, archdeacon of St. Andrews, 1231.

Robert, abbot of Dunfermline, 1249.

Garneline, archdeacon of St. Andrews, 1250—1256.

Richard, bishop of Dunkeld, 1256 (Fordun).

William Wischart, archdeacon of St. Andrews, 1256—1273.

Robert, abbot of Dunfermline, 1273.

William Fraser, dean of Glasgow, 1273—1280.

Sir Thomas de Carnotto, or Charteris, 1280—1285.

Alan de Edmund, bishop of Caithness, 1291. He was made C. by King Edward I. of England, who also associated in office with him Walter de Agmodescham (Aylmer's Cat., 105), and thereafter Adam de Bodington, who is V.C. 1291* (Rot. Scot., 9), and C. in December of the same year, the bishop of Caithness having previously died.

Alan de Dunfries, parson of Dumbarton, 1292 (Rot. Scot., 13).

Alexander Kennedy, 1296.

Walter de Agmodescham, 1296.

Mattheus, bishop of the Isles, 1298.

Nicolas de Blamyle, parson of Calder, 1301. In 1307 he was put into the see of Dunblane, and then perhaps resigned, for

William de Bevercotes is C. about that time.

Bernard de Linton, abbot of Arbroath, 1315.

Walter de Twynham, canon of Glasgow, 1327.

William Brisbane, 1332.

Sir Thomas de Carnotto, 1342—1346.

William de Caldwell, prebendary of Glasgow, 1349.

Patrick de Lenchars, bishop of Brechin, is C. 29 Dav. II. and upwards to the reign of Rob. II.; yet Adam, bishop of the same see, is in office 31 Dav. II. (Keith's Bishops, edit. Russel, p. 565).

John de Carrieh, canon of Glasgow, 1370.

John de Pebles, canon of Glasgow, 1377, and *semble* onwards to 20 Rob. II. (Keith's Bishops, edit. Russel, p. 65); but in his absence about 1380 John Forrester of Crostorphine was keeper of the seal, 19 Rob. II.; and from about 1389 to the end of 1395 Alexander Cockburn of Langton was keeper.

Duncan, B.D., archdeacon of Glasgow, 1395.

Gilbert, canon of Glasgow, bishop of Aberdeen, 1396 to 1423; in which last year he was abroad, and Sir John Forrester of Crostorphine was keeper.

William, canon of Glasgow, bishop of Glasgow, 1423.

John, canon of Glasgow, bishop of Glasgow, 1426.

Sir William Crichton, 1440.

James Kennedy, bishop of St. Andrews, 1441.

James Bruce, bishop of Dunkeld.

Sir William Crichton again, 1447.

George, bishop of Brechin, April 19, 1448 (Keith's Bishops, edit. Russel, p. 566).

William, earl of Orkney, 1455.

George Sharnwood, bishop of Aberdeen, 1458.

Andrew, Lord Avenale, 1460.

John, bishop of Brechin, September 6, 1480 (Keith's Bishops, edit. Russel, p. 566).

John, canon of Glasgow, bishop of Glasgow, 1482.

James, canon of Glasgow, bishop of Dunkeld, 1483.

Colin, earl of Argyll, 1483.

William Elphinstone, bishop of Aberdeen, 1488.

Colin, earl of Argyll again, 1488.

Archibald, earl of Angus, 1493.

George, earl of Huntley, 1498.

James, duke of Ross, archbishop of St. Andrews, 1502.

Andrew Foreman, bishop of Moray, 1506.

Alexander, bishop of St. Andrews, 1511 (Keith's Bishops, edit. Russel, p. 34).

Beaton, abbot of Dunfermline, 1513. In 1525, on the removal of the duke of Albany from the regency, the earl of Angus turned Beaton, now bishop of St. Andrews, out of the chancellorship, which, on several other offices, he then engrossed to himself. On Angus's fall the place was given, in 1528, to Gavin Dunbar.

* Hodkin's *Scottish Bishops* had a mark a day for his salary (Aylmer's Cat., 107). In 1309 the salary of the chancellor was 130*l.* 6*s.* 8*d.*

archbishop of Glasgow, in whose time the college of justice was instituted. The series of chancellors may not be further continued. By art. 24 of the treaty of Union, it was provided that there should in future be but one great seal for the United Kingdom, and that a seal should be kept and used in Scotland for such private rights or grants as had usually passed the great seal of Scotland. The office of chancellor of Scotland then properly expired, and none have been appointed to it since the earl of Seafield, who was chancellor at the time of the Union.

CHANCERY (*Cancellaria*); the term is derived from Chancellor, *Cancellarius*, and signifies the court where that judge exercises his functions. There are several chanceries, as there are several chancellors; but the place where the Lord High Chancellor's judicial functions are exercised is especially called the Chancery.

The principal part of the business of the Court of Chancery consists in the administration of equity, a name which in this country comprehends a particular set of rules, having the force of law, which are applicable to such matters as belong to the jurisdiction of the court. The Court of Exchequer, and within certain small districts various local courts also have a similar jurisdiction. For a particular account of the procedure in Courts of Equity, and a history of the origin of that jurisdiction, see *Equity*.

The Lord Chancellor, the Vice-Chancellor, and the Master of the Rolls are the judges by whom equity is administered in Chancery. Each of these has a separate court. These courts have no fixed or permanent situation. In term they are held in Westminster Hall; in Vacation, the first two in Lincoln's Inn, and the last at the Rolls, in Chancery-lane.

The Court of Chancery is a name which, it seems, properly belongs to the Lord Chancellor's Court and the Vice-Chancellor's Court together; it is sometimes applied to the former alone, but most frequently to all the three courts together. The proper presiding judge in the Lord Chancellor's Court is the Lord High Chancellor himself.

The Master of the Rolls is appointed by the crown by letters patent, and holds his office for life. He administers equity in a separate court, called the Rolls. He has the power of hearing and determining originally the same matters as the Lord Chancellor, excepting cases in lunacy and bankruptcy; but all orders and decrees pronounced by the Master of the Rolls must be signed by the Lord Chancellor before they are enrolled. The Master of the Rolls has precedence next to the Lord Chief Justice of the King's Bench. This office is one of high antiquity. The salary is reckoned about 5000*l.* a year.

The office of Vice-Chancellor was created by stat. 53 Geo. III. c. 24. This officer (who takes precedence next to the Master of the Rolls) is appointed by the crown by letters patent, and holds his office during good behaviour. He has power to hear and determine all matters depending in the Court of Chancery either as a court of law or as a court of equity, or as incident to any ministerial office of the court, or which are subjected to the jurisdiction of such court or of the Lord Chancellor by any special Act of Parliament, as the Lord Chancellor shall from time to time direct. But all orders and decrees of the Vice-Chancellor must be signed by the Lord Chancellor, and the Vice-Chancellor has no power to alter or discharge any decree or order made by the Lord Chancellor, unless authorised by the Lord Chancellor, nor any power to alter or discharge any order or decree of the Master of the Rolls. The salary is 5000*l.* a year.

Each of these judges has nearly an equal share of original power to dispense equity. An appeal (which, strictly speaking, is nothing more than a re-hearing of the cause) may be made from any decision of the Master of the Rolls or Vice-Chancellor to the Lord Chancellor, and the court of the latter has been of late years principally occupied with such appeals, original causes being generally confined to the Courts of the Master of the Rolls and the Vice-Chancellor.

Besides the judges just mentioned, there are other officers of the Court of Chancery by whom certain parts of the equitable jurisdiction are exercised. These officers have however no original power for this purpose, but derive all their authority from special delegation by one of the three judges in Chancery. The principal of these officers are the Masters in Ordinary, and the Accountant-General. The Masters in Ordinary are ten in number, besides the Master of the Rolls, who is the chief of them. They were

formerly appointed by the Lord Chancellor, but are now appointed by the crown, and hold office *quamdiu bene se comportant*. (Stat. 3 & 4 Wm. IV. c. 94.) Their salary is 2500*l.* a year. It is the duty of the Masters to execute the orders of the court upon references made to them, whether in exercise of its original jurisdiction, or under the authority of an act of parliament, and by reports in writing, to show how they have executed such orders. It would be impossible to specify every head of reference to the Masters, because they are almost as numerous as the subjects of the court's jurisdiction. The principal subjects of reference are, to examine into any alleged impertinence contained in pleadings, and into the sufficiency of a defendant's answer; to examine into the regularity of proceedings taken in any cause, or into alleged contempt of court; to take the accounts of executors, administrators, and trustees, or between any parties whatsoever; to inquire into, and decide upon, the claims of creditors, legatees, and next of kin; to sell estates, and to approve of the investment of trust-money in the purchase of estates, and, for this purpose (or for any other, as the case may be), to investigate titles, and settle conveyances; to appoint guardians for infants, and to allow proper sums for their maintenance and education; to tax the costs of the proceedings in any suit, or under the orders of the court; and generally to inquire into and inform the conscience of the equity judge upon all matters of fact, which are either disputed between the parties, or not so far ascertained by evidence as to preclude all doubt on the subject.

The *Accountant-General* is an officer created by the stat. 12 G. I. c. 32, which also regulates his duties. All money and effects belonging to suitors of the court (which are the subject of a suit), are deposited in the name of the Accountant-General with the Bank of England, which has the general custody of such money and effects, as the banker of the court subject to its orders. It is the duty of this officer to keep an account with the Bank according to the several causes and accounts to which such money and effects severally belong.

Besides the jurisdiction, of which a sketch has been given above, a summary jurisdiction, upon petition only, without bill and answer, has been given to Courts of Equity in certain cases by acts of parliament. The principal cases in which this summary jurisdiction has been granted are those where trustees or mortgagees die without heirs or leaving infant heirs, or where trustees are out of the jurisdiction, or refuse to convey property to the persons beneficially entitled to it. In these, and many similar cases (which it is unnecessary to mention at large), the court is empowered, upon petition of the parties beneficially interested, to direct a conveyance or assignment of the property held in trust or on mortgage by the infant, or in case of a trustee having died without heirs, or being out of the jurisdiction of the court, or refusing to convey, to appoint some other person to convey in his place. The principal statutes relating to this branch of the jurisdiction of the court are, 1 Wm. IV. c. 47, 1 Wm. IV. c. 60, 1 Wm. IV. c. 65, 4 and 5 Wm. IV. c. 23, 5 and 6 Wm. IV. c. 17.

The stat. 52 G. III. c. 101 gives the court (and the court of Exchequer) a summary jurisdiction in cases of abuse of charitable trusts. The court also exercises a jurisdiction of appointment of guardians for infants upon petition merely.

The jurisdiction exercised in Chancery over *infants* and *charities* is partly derived from the general equity jurisdiction, and partly from acts of parliament. (As to the origin of the jurisdiction over infants, see Coke upon Litt., by Hargrave, 88 b. n. 16; 2 Fombl. on Rq., p. 226, 232).

The jurisdiction over infants is exercised principally in directing *maintenance* to be given them out of the property which they will enjoy on attaining their full age; in appointing and controlling *guardians* of them; and in providing suitable *marriages* for them. It is shared by the three Chancery judges; and the working of it is assisted by the ministrations of the masters and other officers of the Chancery.

The same observations apply to the jurisdiction over *charities*, which amounts to a general superintendence of them, limited however in many cases by the special terms of the charters or acts of parliament by which they are regulated.

A distinct part of the business in Chancery, though but a small part, arises from what is called the *common law jurisdiction of the Court of Chancery*.

It has chiefly respect to actions by or against any officer

or minister of the Chancery, and to judicial proceedings respecting the acts of the king, when complained of by a subject. 3 Bl. Com. 48.

In actions depending in the Court of Chancery by virtue of its common law jurisdiction, the court has no power to try issues of fact. For this purpose the record of the pleadings must be delivered to the Court of King's Bench, and that court will have the issues tried by jury, and give judgment in the actions; and, from a judgment on demurrer in this court, it is said that a writ of *error* lies to the Court of King's Bench. See 3 Bl. 49.

To the common law jurisdiction of the Court of Chancery belongs the power of issuing certain writs; particularly the writ of *habeas corpus*, and the writs of *certiorari* and *prohibition*, for restraining inferior courts of justice from assuming unlawful authority. See 1 Madd. Chanc. 17, &c.

This jurisdiction may be exercised by the Vice-Chancellor as well as the Chancellor, but not by the Master of the Rolls. 1 Madd. Chanc. 22.

The place where the common law jurisdiction of the Court of Chancery is exercised is the *petty bag office*; which is kept solely for this purpose. No part of the ordinary business of the Court of Chancery is carried on there.

The Court of Chancery, in respect of its common law jurisdiction, is said to be a court of *record*, which, as a court of equity, it is not. Spelm. Gloss. 3 Bl. Com. 24.

'In this ordinary or legal court,' says Blackstone (vol. iii. 49), 'is kept the *officina justitie*, out of which all original writs that pass the great seal, all letters patent, and all commissions of charitable uses, bankruptcy, sewers, idemity, lunacy, and the like do issue. The issuing of original writs however is now unfrequent. These writs, which were formerly the foundation of all actions in the courts of law at Westminster, have, with few exceptions, been abolished by recent statutes. Commissions of bankruptcy also are now never issued, owing to the late alterations in the bankrupt law. [BANKRUPT.]

In imitation of the High Court of Chancery in England, various local courts of equity have sprung up in the British dominions and dependencies. Some of these are called Courts of Chancery, and therefore are here noticed. In each of the counties palatine of Lancaster and Durham, and in Ireland, there is a court so named, which dispenses the same equity within the limits of its jurisdiction, as the High Court of Chancery. In the Irish Court of Chancery the Lord Chancellor for Ireland presides. From these courts the appeal is immediately to the House of Lords.

In most of our colonies there are Courts of Chancery (Howard's *Laws of the Colonies*). The equity administered in these however appears not to be the settled system which exists in this country, since the governors of the colonies preside in them. From the colonial courts an appeal now lies to the judicial committee of the Privy Council. Stat. 2 and 3 W. IV. c. 92.

Many of the states of North America have their courts of Chancery; but the equitable jurisdiction of some of these are, it seems, more discretionary than that of our own Courts of Equity. In others of the states the Courts of Equity which formerly existed have been abolished. (See Parkes's *Statutes and Orders of the Court of Chancery of the State of New York, &c.*; An *Essay on Equity in Pennsylvania*; by A. Laussat, jun.; and 6 *Law Mag.*, 127.)

CHANCERY, INNS OF. [INN.]

CHANDLER, DR. RICHARD, was born at Elton in Hampshire, in 1738, studied at Winchester School, and afterwards entered Queen's College, Oxford, in May, 1755. Soon after he took his bachelor's degree in May, 1759 he published 'Elegiaca Græca,' containing the fragments of Tyrtæus, Simonides, Meleager, Alceus, &c., with notes. In 1763, he edited the splendid work 'Marmora Oxoniensia. [ARUNDEL MARMORAE.] In 1764 he was sent by the Dilectant Society to travel into Asia Minor and Greece, pany with Revett the architect, and Pers the painter spent more than a year in Asia Minor; and, in 1 proceeded to Athens, and passed another year in ex Attica and the Peloponnesus. They returned to England in November, 1766. The result of their labours, the 'Antiquities, or Ruins of Magnificent and Famous Buildings in Ionia,' 2 vols. fol. was published in London, in 1769. In 1774, Chandler published 'Inscriptiões Antiquæ pleræque nondum editæ in Asia Minore et Græciâ,

protestant Athenis collecta, 4to., Oxford. His 'Travels in Asia Minor, 4to., 1774, and 'Travels in Greece, 4to., 1776, still rank among the best descriptions of those countries. There is a French translation (Paris, 1806) of the 'Travels in Asia Minor and in Greece, with notes, by J. P. Servois and Barbic de Bèzege. These two works have been since republished together, by the Rev. R. Churton, with *Remarks*, and a biography of I. Chandler, 2 vols. 8vo. 1833. In 1773 Chandler took the degree of D.D., and in 1779 he obtained the living of East Worldham and West Tisted, Hants. In 1785 he married, and afterwards travelled in Switzerland and Italy. In 1800, he was made rector of Tylehurst in Berkshire, when he published his 'History of Ilium, or Troy, including the adjacent country and the opposite coast of the Chersonesus,' 4to., London, 1802, in which he refuted Bryant's assertion, 'that the Trojan war was a fiction, and that no such city as Troy in Phrygia ever existed; and he vindicated the veracity of Homer, and especially the truth of his local descriptions. Dr. Chandler died in February, 1810, in his seventy-second year. He left in MS., 'the Life of William Wainfleet, Bishop of Winchester, Lord High Chancellor of England in the reign of Henry VI., and Founder of Magdalen College,' which was published 8vo., London, 1813.

CHANTILLY, a small town in the department of Oise, on the road from Paris to Amiens, 23 miles from Paris. The houses of this little town are neatly built, and roofed with slate. A handsome street was built by the last Prince de Condé, as well as a richly-endowed hospital, a model for institutions of that kind. The population of Chantilly in 1832 was 2524. Chantilly is the centre of a considerable manufacture of lace, a branch of industry introduced here about the year 1750. There are a large establishment for spinning cotton yarn and manufacturing cotton prints, in which 500 or 600 work-people are employed, and a porcelain manufactory. At one entrance to the town is an hydraulic machine to supply the hospital and the public fountain.

Chantilly existed as a village, with its château, as early as the year 900. It belonged formerly to the families of Orgeмонт and Montmorency, but owes its prosperity chiefly to the illustrious family of Condé, to which it belonged from the time of Louis XIII. At the massacre of St. Bartholomew it belonged to the family of Montmorency; and the remains of the great Coligny, who was connected with that family, having been taken down secretly by some of his servants from the gibbet of Montfaucon, where they had been exposed, were transported to Chantilly and deposited in the chapel of the château, from whence they were afterwards removed to the parish church. By a singular error of the peasantry, the women of the neighbourhood resort to this tomb to make their offerings to 'St. Gaspard de Coligny' for the cure of their diseased children, thus transforming a Huguenot martyr into a Catholic saint. It was to Chantilly that the great Condé (so called) retired when the gout had incapacitated him for the fatigues of warfare, and where Molière, Racine, and Boileau came to amuse his leisure hours. The old château was pulled down and a new one erected by the Duke of Bourbon, about the end of 1718. This edifice was one of the most splendid residences in Europe, and its attractions were increased by the domain, the vast park (planted and laid out in alleys, and surrounded by a wall), the gardens, the menagerie, &c., attached to it. The revolution ruined Chantilly, or nearly so; the château itself was destroyed, but some of the out-buildings remain, as the smaller château, the palace of Enghien, the dog-kennels, and the stables, which, by their size and their architecture, are almost entitled to be termed palaces.

CHANTRY, (Cantaria, in the middle age Latin), a private religious foundation of which there were many in England before the Reformation, established for the purpose of keeping up a perpetual succession of prayers for the prosperity of some particular family while living, and the repose of the souls of those members of it who were deceased, but especially of the founder and other persons specifically named by him in the instrument of

most, always began with 'Orate pro animâ,' which was an appeal to those who resorted to the churches to remember in their serious hours to pray for the soul of the person who slept below. Princes and persons of great wealth, when they founded monasteries, included, amongst the duties of the religious for whose use they gave them, that they should receive in them their earthly remains, and for ever make mention of them in their daily services. When the taste for founding monasteries declined, which may be referred to about the close of the twelfth century, the disposition to secure the same object, by the foundation of chantries, began to prevail extensively in the better classes of society, and it continued with unabated zeal to the very eve of the Reformation, when all such foundations were swept away as superstitious.

A chantry did not necessarily require that any edifice should be erected for it. Chantries were usually founded in churches already existing; sometimes the churches of the monasteries, sometimes the great cathedral or conventual churches, but very frequently the common parish church, whether in a town or in a rural district. All that was wanted was an altar with a little area before it and a few appendages; and places were easily found in churches of even small dimensions in which such an altar could be raised without interfering inconveniently with the more public and general purposes for which the churches were erected. An attentive observation of the fabric of the parish churches of England will often detect where these chantries have been, in some small remains perhaps of the altar, which was removed at the Reformation, but more frequently in one of those ornamented niches called piscinas, which were always placed in proximity with the altars. Sometimes there are remains of painted glass which it is easy to see has once been the ornament of one of these private foundations, and more frequently one of those arched recesses in the wall which are called Founders' Tombs, and which in many instances no doubt were actually the tombs of persons to whose memory chantries had been instituted.

In churches which consisted of only nave and chancel with side aisles, the eastern extremities of the north and south aisles were often seized upon for the purpose of these foundations; in the larger churches, having the platform resembling the cross on which the Saviour suffered, the transverse beams were generally devoted to the purpose of these private foundations. In the great conventual churches and the churches of monasteries, it would appear as if provision were often made for these private chantries in the original construction, each window that looks eastward being often made to light a small apartment just sufficient to contain an altar and a little space for the officiating priest.

It was by no means unusual to have four, five, or six different chantries in a common parish church; while, in the great churches, such as old St. Paul's in London, the Minster at York, and other ecclesiastical edifices of that class, there were at the time of the Reformation thirty, forty, or fifty such foundations. When the fabric of a church afforded itself no more space for the introduction of chantries, it was usual for the founders to attach little chapels to the edifice, it is these chantry chapels, the use and occasion of which are now so generally forgotten, which occasion so much of the irregularity of design which is apparent in the parish churches of England. Erected also as they generally were in the style of architecture which prevailed at the time, and not in accommodation to the style in which the original fabric was built, they are a principal cause of that want of congruity which is perceived in the architecture of different parts of the parish churches.

When chapels were erected for the especial purpose of the chantries, they were usually also the places of interment of the founder and his family, whence we sometimes find such chapels belonging, even to this day, to particular families, and adorned with monuments of many generations. One of the most beautiful chapels of this kind is in the little village of Sandal, a few miles from Doncaster, the foundation of Rokeby, archbishop of Dublin, who died in 1521. The church of Sandal being small afforded no scope for the design of this magnificent prelate. Having therefore determined that here should be the place of his interment and the perpetual celebrations in his memory, he erected a chapel on the north side of the choir, open however to the church on one side, being separated from it only by open wainscot. On entering it by the door one sees at once the whole economy of one of these chapels. Under the window looking

Chantries owed their origin to the opinion so generally prevalent in the Christian church of the efficacy of prayer in respect of the dead as well as the living. Amongst the English, always a devout people, it prevailed in all ranks of society, and was especially of the founder and other persons specifically named by him in the instrument of

eastward an altar has stood; the piscina on the right remains. On each side of the east window is a niche where once, no doubt, stood an effigy of a saint whom the archbishop held in peculiar honour. In the centre is a brass indicating the spot in which the body of the prelate lies; and in the north wall is a memorial of him, having his arms and effigy, with an inscription setting forth his name and rank and the day of his decease, with divers holy ejaculations. The stone and wood-work have been wrought with exquisite care, and the windows appear to have been all of painted glass.

Sometimes chantries were established in edifices remote from any church, a chapel being erected for the express purpose.

In chantries of royal foundation, or in chantries founded by the more eminent prelates or barons, the service was conducted sometimes by more than one person. But usually there was but one officiating priest. The foundation deeds generally contain a distinct specification of his duties, which consisted for the most part in the repetition of certain masses, but sometimes the instruction of youth and the delivering pious discourses to the people made part of the duty of the chantry-priests. They also contain an account of the land settled by the founder for the support of the priest. The names of the persons whom he was especially to name in his services are set forth, as well as the mode of his appointment and the circumstances in which he might be removed. Generally the king was named together with the founder and members of his family. This, it was supposed, gave an additional chance of the foundation being perpetuated. The king's licence was generally obtained for the foundation.

In many towns and country places there are ancient houses known by the name of chantry houses, or sometimes chantries, or colleges. These have been places of residence of the chantry priests, and when called colleges, where they lived, a considerable number of them being in one church, a kind of collegiate life, it being held that the clergy should mix but little with the laity. These, as well as all other property given for the support of the chantry priests, were seized by the crown and sold to private persons, when by an act passed in the first year of King Edward VI., cap. 14, all foundations of this kind were absolutely suppressed and their revenues given to the king. An account had been taken a few years before of all the property which was settled to these uses, by the commissioners under the act 26 Hen. VIII., cap. 2, whose returns form that most important ecclesiastical document the 'Valor Ecclesiasticus' of King Henry VIII. The 'Valor' has been published by the commissioners on the 'Public Records' in five volumes folio.

CHAPEL, in Latin *capella*, a word common to many of the languages of modern Europe, and used to designate an edifice of the lower rank appropriated to religious worship. Its origin and etymology are very obscure.

In England it has been used to designate minor religious edifices founded under very different circumstances, and for different objects.

1. We have a great number of rural ecclesiastical edifices, especially in the north of England, where the parishes are large, which are not, properly speaking, churches, *ecclesie*, though in common parlance they are sometimes so called, but are chapels, and not unfrequently called parochial chapels. Most of these are of ancient foundation, but still not so ancient as the time when the parochial distribution of England was regarded as complete, and the right to tithes and offerings determined to belong to the rector of some particular church. In the large parishes it frequently occurred that a family of rank which resided at an inconvenient distance from the parish church would desire to have an edifice near to them, to which they and their tenants could resort for the enjoyment of the benefit of Christian ordinances. On reasonable cause being shown, the bishop would often yield to applications of this kind; but in such cases he would not suffer the rights of the parish church to be infringed; no tithe was to be subtracted from it and given to the newly erected foundation, nor was that foundation to be accounted in rank equal to the older church, or its incumbent otherwise than an inferior and subordinate minister to the incumbent of the parish church. But the bishop generally, perhaps always, stipulated that there should be an endowment by the founder of such an edifice. Not unfrequently in edifices of this class there was the double purpose of obtaining a place of easier resort

for religious worship and ordinances, and a place in which perpetual prayers might be offered for the family of the founder. [CHANTRY.] Others of these rural chapels were founded by the devotion of the parishioners. The population of a village, which was remote from the church of the parish within whose limits it was included, would increase, and thus the public inconvenience of having to resort to the parish church on occasion of christenings, churchings, marriages, and funerals, besides the services of the festivals, became great; they would therefore apply to the bishop in petitions, many of which are to be found in the registers of the sees, setting forth the distance at which they lived, the impediments, constant or occasional, in the way of their ready resort to their parish church, as want of good roads, snow, the rising of waters, and the like, on which the ordinary would grant them the leave which they desired, reserving, however, as seems almost always to have been the case, whatever rights and emoluments had heretofore belonged to the parish church. In the parish of Halifax there are twelve of these chapels, all founded before the Reformation. In the parish of Manchester, and in most of the parishes of Lancashire, such subsidiary foundations exist in great number. Those foundations of this class which could be brought within the description of superstitious foundations were dissolved by the Act of Edward VI. for the suppression of chantries; but while the endowment was seized, it not unfrequently happened that the building itself, out of the piety of the person into whose hands it passed in the sale of the chantry lands, or the devotion of the persons living near it, and long accustomed to resort to it, continued to be used for religious worship in its reformed state, and remains to this day a place of Christian worship, the incumbent being supported by the casual endowments of the period since the Reformation, and especially by what is called Queen Anne's Bounty, in which most of the incumbents of chapels of this class have more or less participated.

2. The term chapel is used to designate those more private places for the celebration of religious ordinances in the castles or dwelling-houses of distinguished persons. We find in the fabrics of some of the oldest specimens of the castles of England some small apartment which has evidently been used for the purposes of devotion; and this sometimes in the keep, the place of last resort in the time of a siege. A remarkable instance of this is at Conisbrough, in Yorkshire. But more frequently chapels of this kind were erected adjoining the apartments appropriated to the residence of the family. Most of the baronial residences, it is probable, had chapels of this kind. How splendid they sometimes were we may see in Saint George's Chapel at Windsor and Saint Stephen's Chapel at Westminster, both chapels of this class attached to the residences of our kings.

3. The chapels of colleges, as in the two universities; of hospitals, or other similar foundations.

4. Chapels for private services, chiefly services for the dead, in the greater churches, as the chapel of Saint Erasmus, and others, in the church of Westminster. Additions made to the parish churches for the purpose of chantries are sometimes called chantry chapels.

5. Places of worship of modern foundation, especially those in towns, are called chapels of ease, being erected for the ease and convenience of the inhabitants when they have become too numerous for the narrow limits of their parish church. Most of these are founded on special Acts of Parliament, in which the rights and duties of the incumbent and the founders are defined.

6. The word chapel is pretty generally used to denote the places of worship erected by various sects of Dissenters under the Act of Toleration, though the Quakers and some of the more rigid Dissenters of other denominations, out of dislike to the nomenclature of an ecclesiastical system which they do not approve, prefer to call such edifices by the name of meeting-houses.

CHAPEL EN LE FRITH, a market-town and in the hundred of High Peak, county of Derby, 21 miles N.W. by W. from Buxton, 21 miles N.W. by N. from Derby, and 207 N.W. by N. from London. It includes the townships of Bowden Edge, Bradshaw Edge, and Coomb's Edge, and contains 234 inhabitants, most of whom are employed in the manufacture of cotton or paper. The Peak Forest lime-works lie three miles east of the town, and communicate by railway with the Peak Forest canal, which runs within three miles to the N.W. in consequence of the

vicinity of which there is a large carrying trade here. There is a small market on Thursday, and numerous fairs in the course of the year for the sale of cattle, wool, and provisions. There are places of worship for the Episcopalians and Wesleyan Methodists. The church, dedicated to St. Thomas à Becket, was rebuilt at the beginning of the last century. The living is a perpetual curacy, in the jurisdiction of the dean and chapter of Lichfield, having 400*l.* private benefaction, 400*l.* royal bounty, and 300*l.* parliamentary grant, and in the gift of the resident freeholders, who choose a committee of twenty-seven from the three townships, by a majority of whom the minister is elected. There is an endowed school at Chapel en le Frith, where nineteen scholars are taught, and another at Bowden's Edge for the instruction of eight girls. A library has been recently established. The town is not lighted, and only partially paved. Its elevation above the level of the sea at low water is 566 feet. The High-Peak court for the recovery of small debts is held here every third week, at which the duke of Devonshire's steward presides. About two miles south is a Roman road and the remains of other antiquities.

CHAPEL HILL. [CAROLINA, NORTH.]

CHAPELAIN, *capellanus*, a word formed immediately on the word chapel, *capella*, according to one of the commonest analogies of our language.

A chaplain is properly a clergyman officiating in a chapel, in contradistinction to one who is the incumbent of a parish church. But its more frequent use is now as designating clergymen who are either (1) residing in families of distinction and actually performing religious services in the family; or (2) who are supposed to be so, though not actually so engaged. This fiction proceeds on the assumption that every bishop and nobleman, with some of the great officers of state, have each their private chapel, to which they nominate a priest, or more than one. Certain privileges respecting the holding of benefices belong to these chaplains, by reservation out of the Act against Pluralities, 21 Henry VIII., c. 13. By the same act the number of chaplains which noblemen and other persons may nominate was limited: an archbishop may nominate eight; a duke or a bishop, six; a marquis or earl, five; a viscount, four; a baron, a knight of the garter, or the lord chancellor, three; the treasurer of the king's house, the comptroller of the king's house, the clerk of the closet, the king's secretary, the dean of the chapel, the almoner, and the master of the rolls, may nominate each two; the chief justice of the King's Bench and the warden of the Cinque Ports, each one; a duchess, marchioness, countess, and baroness, being widows, are allowed to nominate each two.

CHAPPE CLAUDE, a French mechanician, who, though not the original inventor of a machine for transmitting intelligence with rapidity between places very distant from each other, must be considered as having devised the means of rendering such a machine available for that purpose. He was a nephew of the Abbé Chappe d'Auteroche, and was born at Brulon, in Normandy, in 1763. It is said by his French biographers that, happening on some occasion in his youth to be separated from his friends, he conceived the idea of corresponding with them by means of signals; and that the result of his efforts to obtain this end, was the invention of the machine which he called a telegraph (*τῆλε* and *γραφῆς*), or a semaphore (*σημα* and *φωρος*). Whether or not he had at that time any knowledge of the discoveries of Dr. Hooke, in England, or of Amontons, in his own country, both of which were nearly a century earlier, is uncertain; but there appears to be some resemblance between his machine and that which was proposed by the former in his discourse to the Royal Society in 1684. Be that as it may, no doubt can exist that M. Chappe is justly entitled to the honour of having invented both a particular system of signals, and the mechanism by which the operations are performed.

The machine consisted of a vertical pillar of wood, fifteen feet high, at the top of which was a transverse beam, seven or twelve feet long, which turned on a joint at the top, and was capable of being placed at any angle with the pillar; and at each extremity of the beam was a secondary arm, which also turned on a joint, and could be moved either in the same direction as the beam, or at any angle with it, upwards or downwards. The various positions of the beam and secondary arms were to serve as indications of the letters of the alphabet, and of the ten

numerals; the sentence to be transmitted was to be exhibited letter by letter from the first telegraph to the next in the line; it was to be repeated in the same manner from the second to the third, and so on to the last.

M. Chappe presented his invention to the French Legislative Assembly in 1792, when the revolution had disposed of the minds of men for the reception of any novelty which promised to be of national utility; and in the following year the government decreed that an experiment should be made, in presence of certain commissioners, in order to try its efficacy. For this purpose there was formed between Paris and Lisle, at distances from each other equal to three or four leagues, a line of stations, at each of which one of the machines was constructed; and the first, which was immediately under the direction of the inventor, was placed on the roof of the Louvre. The sentence to be conveyed was received there from the hands of the members composing the Committee of Public Safety, and in 13 minutes 40 seconds, it was delivered through all the intermediate stations to that at Lisle, a distance of 48 leagues. The result of the experiment being considered satisfactory, the use of the machine became general in France; and it is said that one of the first dispatches conveyed in this manner to Paris announced the re-taking of the town of Condé.

The important advantages which might be derived from the use of the telegraph were immediately felt. A description of it was brought by an emigrant from Paris to Frankfort on the Maine, where two models were executed, which, from thence, were sent to England by Mr. W. Playfair; and the invention, with modifications, was adopted in this country.

The claim of M. Chappe to the honour of being the inventor of this kind of machine appears to have been disputed by some of his contemporaries, who also invidiously represented its imperfections or exposed the mistakes which, as they asserted, might be made in using it; and these circumstances are said to have so preyed on his mind, that he fell into a profound melancholy, which terminated his life in 1805, at the age of 42 years.

CHAPPE D'AUTEROCHE, JOHN, born 1722 (1728, Delambre), died, 1769, in California, whither he had gone to observe the transit of Venus. He succeeded Lacaille at the observatory of Paris, as assistant to Cassini de Thury, and published Halley's Tables, in 1754. For his travels to Siberia and to California, &c., see Delambre's *Hist. d'Astron.* XVIII. siècle.

CHAPTAL, JEAN ANTOINE, a distinguished French chemist, was born in 1756, at Nozaret (Larçre). His education commenced at Mende, from whence he repaired to the School of Medicine at Montpellier, and afterwards to Paris. In 1781 he was appointed to the Chemical chair recently founded by the States of Languedoc. Inheriting a large fortune from his uncle, he established some important chemical manufactories in his adopted city, and thus bestowed upon France several valuable products which were previously obtained from foreigners. In 1793 Chaptal was called to the capital by the Committee of Public Safety, to manage the manufactory of salpêtre, which substance could no longer be obtained from India, and the want of which was pressing. The great establishment of Grenelle thus became the scene of that zeal and ability of which Chaptal gave so many proofs during the whole of his existence. He was one of the first professors of the Polytechnic School; and the Institute elected him a member in the place left vacant by the death of Paven. After the establishment of the consulate, Napoleon called him to the Council of State. In the year 9 (1801) he appointed him Minister of the Interior, and towards the end of the year 12 he retired from these high appointments. During his administration of four years he conferred many benefits upon the state. Devoting much time to the examination of charitable establishments, which had suffered from the misfortunes of the times, he liquidated their debts; and originated several new institutions for the amelioration of the condition of the poor. As might however be expected from his habits, it was to the manufacturing interests of his country that his attention was principally directed; he established chambers of commerce, and consulting councils of arts and manufactures; the School of Arts and the Conservatory, which have become an important seminary and a great museum, are monuments of his enlightened solicitude for increasing the opportunities and means of instruction. He published useful processes, visited the manufactories,

conversed with the workmen, offered them his advice, applauded their discoveries, and encouraged the importation of processes and apparatus from abroad; in fact, he extended his views and his care to every substance and circumstance which he considered favourable to the improvement of manufactories.

M. Thénard, in his discourse pronounced in the name of the Academy of Sciences, has thus drawn the character of Chaptal: 'He was endowed with a kind heart, of a mild and gentle character, moderate in tastes and opinions, full of benevolence towards every one, of affectionate regard for his associates, of devotion to his friends; ready to confer a favour when in his power, and doubling it by the grace with which he conferred it; unhappy when compelled to refuse, and always softening the refusal by expressions which showed the goodness of his heart. Possessing a handsome fortune, which he had honourably acquired, and loaded with honours, Chaptal seemed safe from reverses. Nevertheless some disappointments which he could not foresee, and certainly did not merit, obscured the close of his brilliant career; but he supported them with dignity, without murmuring, and without breathing a complaint, and so as entirely to evince the soundness of his mind. He consoled himself among his friends, by study, and by fulfilling duties which had been imposed upon him, or which he had created for himself. Too well informed not to understand the nature of his disease, and feeling his end approaching, he resigned himself like a philosopher, and making the requisite arrangements for leaving a world where he had but few days to remain, he died beloved and surrounded by his numerous family, bestowing on them his blessing as his last farewell.' He died at Paris, 29th July, 1832, in the 76th year of his age. He was a senator under the Empire, and at the time of his death he was Peer of France and a Grand Officer of the Legion of Honour. He was one of the first founders of the Society of Encouragement, over which he presided many years.

Chaptal's principal works are 'Elémens de Chimie,' 3 vols., 8vo. The first edition appeared in 1790, and the fourth in 1803. It has been translated into most languages. 'Essai sur le Perfectionnement des Arts Chimiques en France,' 8vo., 1800; 'Art de Faire, de Gouverner, et de Perfectionner les Vins,' 1 vol., 8vo. (first edition 1801, second, 1819); 'Traité théorique et pratique sur la Culture de la Vigne,' 2 vols., 8vo. (first edition, 1801; second in 1811); 'Art du Teinturier et du Dégraisseur,' 8vo., 1800; 'Essai sur le Blanchiment,' 8vo., 1801; 'Chimie appliquée aux Arts,' 4 vols., 8vo., 1807; 'Art de la Teinture du Coton en Rouge,' 8vo., 1807; 'De l'Industrie Française,' 2 vols., 8vo., 1819; 'Mémoire sur le Sucre de Betterave,' 8vo. (first edition, 1815; second edition, 1821); 'Chimie appliquée à l'Agriculture,' 2 vols., 8vo. (first edition, 1823; second edition, 1829).

CHAPTER. The canons in the cathedral or conventual churches, when assembled, form what is called the chapter, *capitulum*, antiently the council of the bishop. [CANON.] Other religious communities, when assembled for business, sat in *chapter*. Attached to many cathedral and conventual churches are buildings for the meeting of the chapter, called chapter-houses. The buildings of this kind connected with the churches of Westminster and York are octagonal and of singular beauty.

The members of the College of Arms, that is, the king's heralds and pursuivants, are said to hold a *chapter* when they sit together to confer on the business of their office.

CHAPTER HOUSE. [CHURCH.]

CHARACEÆ, a curious group of plants inhabiting pools and slow streams, to which they communicate a nauseous offensive odour, which is said to become a pestilential miasma when, as in the Campagna of Rome, the plants are in great numbers. They are jointed leafless plants, with verticillate branches, composed either of one or of several tubus adhering in bundles, and either encrusted with calcareous matter (Chara), or transparent (Nitella). Botanists are not agreed whether they are flowering or flowerless plants, their organs of reproduction being of so anomalous a nature as to correspond with nothing that has been observed in other plants. One of these organs, named a nucule, is an oval sessile spirally striated body, with a five-cleft apex, and a number of grains in its interior; this has been looked upon as the pistil, and has been seen to grow a young plant. The other, called the globule, is a 1st body consisting of triangular scales, inclosing a

mass of elastic wavy threads, and has been named an anther. There is, however, no proof that it acts as a male organ, and it has no apparent analogy with the genuine anthers of flowering plants. Hence it is most generally thought that Characeæ constitute a small group among the flowerless class of the vegetable kingdom. They are highly interesting on account of the facility with which they exhibit the circulation of their fluids, and because of the light they thus appear to throw upon some of the more obscure of the phenomena of vegetable life. If one of the tubes of a chara be observed under a pretty good microscope, by the aid of transilluminated light, the fluid it contains will be distinctly seen to have a motion up one side of each tube, down the other, and then up again, after the manner of a jack-chain, and this goes on continually as long as the plant remains alive. No spectacle that we are acquainted with is more beautiful than this, if it is well seen with the aid of a good microscope. It is so interesting indeed that a microscope for the purpose of viewing it has been invented by Mr. Horsemun Solly. Of this and the phenomena in the Chara, a good account will be found in the *Transactions of the Society of Arts*, vols. xlix. and l.

[Chara.]

a, a portion of tubular stem, showing the bases of a whorl of leaves; b, leaf, bearing the organs of fructification; c, a single organ of fructification, greatly enlarged; d, upright section of the fruit; e, plant germinating.

CHARACTERISTIC (of a logarithm). The whole number, position, or negative, which precedes the decimal point of a logarithm. The reason of this number having a separate name is, that in Briggs's system it is commonly found as not to form a part of the tables. [LOGARITHM.]

CHARADE, a species of riddle, in which a word consisting of several syllables is indicated, first by an enigmatical description of each syllable, taken separately, and then by a similar description of the whole. It does not seem to be necessary that the word should consist only of two syllables, according to the definition given in most of our English dictionaries and cyclopaedias. To have anything of wit or point, a charade should be so contrived that the ideas employed to denote or suggest the several syllables, and the entire word, shall be all in some way associated together, or arise naturally the one out of the other. This however is often neglected. A little book, professedly intended for the amusement and instruction of young people, has lately been published under the title of 'Five Hundred Charades from History, Geography, and Biography,' by Eliza Wakefield, in which there is not, we believe, any

real Charade, according to the meaning which the word must be understood to have even as a species of false wit; for certainly there is no wit of any kind in describing, for instance, the word *Eton*, by saying that its first syllable is a word signifying what we all do, second, a preposition; and its whole, a town in Buckinghamsire noted for its public school. There is no more wit in this than there is in simply spelling the word. There is a little German work entitled 'Rätsel und Charaden zur Schärfung der Denkkraft für die Jugend,' Nürnberg, 1817, which appears to have something of the same design with Miss Wakefield's performance, but to be much more artificially compiled. The following, which we find in the late editions of the dictionary of the French Academy, is not a bad example of a French Charade: 'My first makes use of my second to eat my third; the translation being the word *chiendent* (dog's tail.)' The word Charade is said to be derived from the name of the inventor of this particular species of enigma. The term appears to be originally French, and not to have come into use till towards the end of the last century.

CHARADRIADÆ. [PLOVERS.]

CHARADRIUS. [PLOVERS.]

CHARADRIAS (Stephens), a genus of moths of the family *Noctuidæ*. Technical characters: wings more or less den- ticated; the posterior wings usually whitish in the males, and brown in the females; palpi short, two-jointed; maxillæ long; antennæ rather long, simple in the females, and more or less pectinated in the males; head small; thorax large, not crested; apex of the body furnished with a tuft of hairs in the males.

Five species of this genus have been found in England; their larvæ are naked, feed upon roots, and assume the pupa state underground.

Charadrius graminis varies from an inch to an inch and a half in width, measured from tip to tip of the wings when expanded; it is of a brownish colour; the upper wings have a longitudinal white streak, which extends beyond the middle, and gives out three branches at the apex: touching this white line above there are two pale brown spots, and another of the same colour beneath, near the base of the wing; the apex of the wing has a row of pointed black spots, more or less distinct.

The caterpillar is of a brownish colour, with yellow streaks on the sides and back: it feeds upon grasses, and is exceedingly destructive to the pastures in Sweden. In England the insect is not so abundant; there is however an instance on record of its having committed considerable devastation in the north of England during the larva state. We allude to an account given by Mr. Wailes, in the second volume of the 'Entomological Magazine,' who observed a portion of the mountain of Skiddaw thus affected—their devastation causing the herbage to have a dry and parched appearance: the part affected comprised at least fifty acres, and extended some distance down the western side of the mountain; and so marked was the line, that the progress made by the larvæ could be distinctly seen from the town of Keswick. Large flocks of rooks were observed to frequent the spot, and no doubt devoured immense numbers; the moths however appeared in great abundance in the month of August. From this same gentleman's observations, we find that the history of the moth is also interesting. It appears to be their habit to fly from about half-past seven to half-past eight in the morning, during which time they are seen in some parts of the country in the utmost profusion; their appearance and disappearance are extremely sudden. The field in which Mr. Wailes observed them became in one moment a moving mass, and after about an hour not a single moth was to be seen, all having disappeared in a manner equally sudden: they fly about three or four inches from the ground, and thread their way with considerable rapidity through the stalks of grass. This moth is by no means abundant in the south of England: it departs a little from the characters of the genus in not having the wings notched.

CHARCAs. [BOLIVIA.]

CHARCOAL is the impure carbon obtained by the decomposition of woody matter by heat without access of air; during this operation the more volatile elements of the woody fibre are expelled as new compounds, while the carbon, the fixed ingredient, remains, mixed however with a small quantity of ash, and some volatile matter, presently to be noticed, which renders

What occurs during the preparation of charcoal will be readily understood by referring to the analysis of woody fibre by MM. Guy Lussac and Thénard, who found, whatever be the kind of wood employed, that after drying at 212° Fahr. it weighed upon an average

Carbon	52
Hydrogen	5.3
Oxygen	42.7

100.0

Now as the oxygen and hydrogen are almost exactly in the proportions required to form water, it would appear, that if these only could be expelled by heat, the products of the decomposition would be carbon and water. We shall however presently mention, that owing to the combination of a part of the carbon with these elements, and also of the oxygen of the air, the compounds which arise from the decomposition of wood are much more complicated, and are of very great importance.

The making of charcoal for domestic uses, and probably also for such manufacturing or metallurgical processes as the ancients were acquainted with, is of high antiquity. Pliny (lib. 16. c. 6.) mentions that the wood was formed into a pile the top of which was covered with clay; evidently to prevent the access of too much air, by which, as experience had no doubt taught, it was found that the wood was converted entirely into ash.

Charcoal is now prepared by two different methods: one resembling in principle that just mentioned, is that of piling the wood in a heap, which is covered with turfs and sand to allow of the entrance of such a portion only of atmospheric air as is sufficient to carry on the imperfect combustion required. The heap is fired at several holes left near the bottom, and a draught of air is obtained by at first leaving an orifice at the top of the heap; this is afterwards covered, and when it is found that the flame has pervaded the heap entirely, the bottom holes are also closed. When the mass has cooled, the charcoal remains.

Within a comparatively few years another method of obtaining charcoal has been adopted, by which the article obtained is said to be better adapted for the purpose of making gunpowder. This is done by putting the wood into iron cylinders, which are set in brick-work and surrounded by fire; the wood in the cylinders has no communication with the external air, and they have only a small opening to allow of the escape of the gaseous products arising from the decomposition of the wood, and the new compounds derived from the combination of its oxygen and hydrogen with a portion of the carbon.

These products, or at least those which are condensable, are chiefly water, tar, impure acetic acid, usually called pyroligneous acid [*PYROLIGNEOUS ACID*], creosote [*CREOSOTE*], pyroxylic spirit [*PYROXYLIC SPIRIT*], and empyreumatic oil. One hundred parts of oak wood dried in the air yielded 43 of pyroligneous acid, about 4.5 parts of carbonate of potash, 9.06 parts of empyreumatic oil, and 26.2 of carbon; different woods yielded somewhat varying proportions of these substances, but the oak gave the largest quantity of charcoal.

Although the charcoal thus procured is preferable for making gunpowder, yet it is stated that it is not so well liked for many other purposes; it is also said to be much lighter than that made in the usual way, and this appears to occasion some variation in the degree of heat required for its consumption in a given time, and thus influences many operations. The densest charcoal gives the most heat while burning.

The general properties of charcoal are, that it is black, sonorous, and brittle, it retains the form of the wood from which it is obtained; it is insoluble in water; infusible and fixed in the most intense heat ever produced. It is a very bad conductor of heat, but conducts electricity. Its property of condensing various gaseous bodies has been already noticed, as well as the compounds which it forms with some other elements. It has considerable antiseptic powers. [*CARBON.*]

It has been mentioned that certain impurities exist in the charcoal of wood; thus when 100 parts of old oak wood are entirely burnt, there remain about 5 parts of ashes, and different woods furnish very different proportions of them; these ashes are principally carbonate of potash [*POTASSA*], unquestionably derived from the decomposition of some salt containing a vegetable acid, as the tartaric or

malic. It appears extremely so, that the spontaneous combustion which charcoal has been known occasionally to undergo, has been occasioned by a portion of this potash having been reduced to its metallic state, and the subsequent action of moisture upon it. For an account of the different quantities of charcoal and bones obtained from different kinds of wood, see Dumas, *Traité de Chimie*, tome i., p. 558; and see also in *Phil. Mag.*, vol. iii., a paper by M. Musiel on the same subject.

CHARCOAL, ANIMAL. Common charcoal possesses to a certain extent the power of destroying vegetable colour; but this property exists in a much higher degree in what is called animal charcoal, or that obtained by the decomposition of the carbonaceous portion of bones. To prepare this, bones are heated in iron cylinders, and the charcoal remains with the phosphate of lime in them, constituting what is commonly called ivory or bone-black; a large quantity of carbonate of ammonia and various gaseous products are formed at the same time.

This ivory-black is used as a coarse black pigment; but it is now become a very important article from its decolouring property, and is extensively used on that account in sugar refining. [Sugar.]

CHARD BEET, a variety of *Beta cicla*, cultivated for the sake of the strong succulent ribs of its leaves, which are boiled and eaten like sea-kail and asparagus. They are ready for table in October and November, but having a strong earthy flavour which no cooking can entirely conceal; they are seldom seen in this country. The French call this Beet *Poirée aux carottes*. It is sown and managed like common beet, but it produces no root fit for the table.

CHARDIN, SIR JOHN, was born at Paris in November, 1643. His father, who was a Huguenot or Protestant, carried on the business of a jeweller in the French capital, and brought up his son to the same profession. As soon however as Chardin was of age, in order to gratify his taste for travelling, and to endeavour the advancement of his fortunes and estate, he left France for the east. During his first journey, which lasted from 1664 to 1670, he visited Persia and the East Indies, and returning to Paris, he published, in 12mo., 'An Account of the Coronation of Solyman III., Schah of Persia.' During his residence in Persia, he gained access to the court, and was appointed agent to the Schah, who commissioned him to make purchases of jewels and trinkets for him in Europe. At the end of 1671 Chardin again departed for Persia, by the route of Constantinople, the Black Sea, and Armenia. He arrived at Ispahan in June, 1673, and remained in Persia till 1677, 'chiefly,' he says, 'following the court in its removals, but also making some particular journeys, as well of curiosity as business, to prosecute my intentions, studying the language, and assiduously frequenting the most eminent and most knowing men of the nation, the better to inform myself in all things that were curious and new to us in Europe.' Few travellers have been so conscientious and pains-taking, or have had such good opportunities of acquainting themselves with the country and the manners and customs of Persia. He spoke the language like a native, he knew Ispahan better than Paris, and he visited nearly every part of the country, traversing, he says, 'the whole length and breadth thereof.'

In April, 1681, he came to London, where he settled as jeweller to the court and nobility. On the 24th of the same month of April, 1681, he was knighted by Charles II., and on the same day married to a young lady, the daughter of a French Protestant refugee, from Rouen. In the following year he was elected fellow of the Royal Society, which had recently been established, and some papers, written by Sir John, appear in the earliest numbers of the Transactions of that society. He continued to carry on a considerable trade in jewels, prosecuting, at the same time, his studies of the oriental languages and antiquities. He did not publish an account of his eastern travels until 1686, and then he only brought out the first part of them, being his journey from Paris to Ispahan. (*Travels of Sir John Chardin*, fol. Lond. 1686.) This volume, with an unfortunate prophecy of future glory and a long reign, was rather pompously dedicated to James II., who, two years later, was driven from his throne. Chardin was a good courtier, but he had obligations to acknowledge to James, as well as to Charles.

The latter King had employed him diplomatically on an important mission to Holland; and in 1683, Sir John had been at the Hague and Amsterdam as agent for the

English East India Company.

11 appeared the second part of his travels. During the latter years of his life he lived at Turin, and, according to an entry in the church books, he was buried at Obiswick, on the 29th of December, 1713. His travels have been translated into various languages, and often reprinted. There is a very good edition (in French) in 4 volumes, 8vo., with plates, published at Amsterdam in 1733, which we have consulted; but the last and best edition is that of Paris, 1811, in 10 vols., 8vo., with notes, by J. G. Le Rouge, which we have not seen.

About sixty years after his death, some MS. notes which Chardin had written in India to illustrate passages in the Scriptures by a comparison of modern eastern manners, and which had long been lost, were recovered by his descendants, who advertised a reward for them. They were nearly all incorporated in Mr. Harmer's 'Observations on divers passages of Scripture, illustrated by books of travels,' &c.

CHARENTE, a river of France, rises in the high grounds between the towns of La Rochefoucauld (department of Charente), and Rochefort (department of Haute Vienne), and flows N.W. through a narrow valley to the neighbourhood of Civray, where it makes a bend, and then flows southward near the town of Ruffec, to Mansle, which is on the high road from Poitiers to Angoulême; at Mansle it receives the united waters of the Tardoire, the Bandiat, and the Bogueure. Its course is then very winding, first westward, and then again southward, to Angoulême, some miles above which it becomes navigable. From Angoulême it flows westward to Saintes, and from thence N.W. in a very winding channel to the Bay of Biscay, which it enters just opposite to the Isle of Oléron. The towns which it passes below Angoulême are Châteauneuf, Jarnac, Cognac (on the left bank), Saintes, Tonnay-Charente, and Rochefort; the two last are on the right bank. The only tributaries of any importance which it receives is the Boutonne, which rises in the department of Deux Sèvres, and becomes navigable at St. Jean d'Angély. The length of the Charente may be estimated as follows:—from the source to Civray, 41 miles; from thence to the point where the navigation begins, 42; from thence to Angoulême, 18; from thence to the sea, 83; total, 184 miles, of which above 100 are navigable.

The basin of the Charente is bounded on the N.E. by a series of heights, which extend in a waving line from the great central mass of the mountains of Auvergne towards the mouth of the Loire, separating this basin from that part of the great basin of the Loire which is traversed by the Vienne. In a narrow valley formed by two parallel branches of this range of heights the Charente takes its rise. On the S.E. the basin is bounded by high land branching off from the heights just mentioned, near the town of Chalus, and running towards the junction of the Dordogne and the Garonne. The undulations of the soil in the district thus enclosed afford shelter, which is favourable to the productions of agriculture. Wheat and maize are grown; calves are reared, and bullocks, mares, and chestnut trees of different kinds (*châtaigniers et marronniers*) yield plentiful crops; and flax is also raised; but the most important object of cultivation is the vine. The brandy of this part of France, known in this country as the Cognac brandy, is the finest that is made, and the exportation is very considerable. Great quantities of gypsum are procured in the valley of the Charente.

The Charente was known to the Romans by the name of Carantonus.

CHARENTE, a department of France, taking its name from the river, just mentioned, and comprehending the former province Angoumois, with part of Saintonge. It is of irregular form, bounded on the N. by the department of Vienne, on the E. by the department of Haute Vienne, on the S.E. by the department of Dordogne, on the S.W. and W. by the department of Charente Inférieure, or Lower Charente, and on the N.W. by the department of Deux Sèvres. Its greatest length is from N.E. to S.W., 75 miles; its greatest breadth measured at right angles to the above, is 53 miles. Angoulême, the capital, is 242 miles from Paris in a direct line S.E.W., or 288 miles, by the road through Orléans, Blois, Tours, and Poitiers. The area of the department is about 17,100 geographical square miles, according to M. Balbi, which is equal to about 2269 square English miles; nearly the extent of the English counties of Stafford and Derby taken together. The population in 1832 was 362,531, or 160 to a square mile.

The N.E. side of the department is traversed by that range of heights mentioned in the last article as separating the basin of the Charente from that of the Loire; the department however extends to these heights, and includes a portion of the plain watered by the Vienne. The heights which skirt the basin of the Charente on the S.E. side traverse the department on the S. part; while on the N.E. side extend the uplands which divide the valley of the Charente itself from that of its tributary the Boutonne. The most extensive plain, that which is watered by the Charente, and occupies the centre of the department. The rivers are, the Charente, and its tributaries, the Tardoire, Bandiat, Bognere, Touvre, and others (all of which are unsuited for navigation, except the Touvre and the Charente to the Vienne, which is not navigable within the limits of the department, and the Dronne, also not navigable, which forms the southern boundary of the department. The inland navigation is therefore confined to the Charente and the Touvre, in the neighbourhood of Angoulême, and below it. The only great road which traverses the department is that from Paris to Bordeaux: there is a third class road which comes from Rochelle, Rochefort, and Saintes, enters the department near Cognac, and runs on to Angoulême, whence two other roads of the same class run, one to the N.E. to Limoges, and thence into central France; the other S.E. to Brantôme and Périgueux.

The nature of the soil, and the agricultural productions have been noticed in the foregoing article, which applies to the central plain of the department, and in the article *Angoulême*, a division under the old monarchy, nearly coinciding with this department. We have only to add here that the quantity of brandy annually produced is estimated at 33,000 puncheons, averaging about 110 gallons each, which are either sent to the other parts of France, or are exported to foreign countries. The number of horned cattle brought yearly into the department, and sent out of it again after being fattened, amounts to 30,000. The soil is considered to be divided in tolerably equal portions between the vineyards, the arable land, and the woods, pasture lands, and wastes. (Malte Brun.)

The department of Charente is divided into five arrondissements—Angoulême in the centre (population in 1832, 128,391); Confolent, or Confolens, in the N.E. (population, 67,222); Ruffec, in the N.W. (population, 58,745); Cognac, in the W. (population, 50,131); and Barbezieux, in the S. (population, 58,042).

The chief towns are, Angoulême, the capital of the department (population in 1832, 15,186); and Barbezieux (population, 2437 for the town, or 2736 for the whole commune) [*Angoulême, Barbezieux*]; Cognac, Confolens, Ruffec, La Rochefoucauld, Jarnac, and Mansle, or Manles.

Cognac, 24 miles W. of Angoulême, is beautifully situated on a small eminence on the left bank of the Charente. It has an ancient castle with a park near it. Under an elm near this castle, Francis I., king of France, was born. His mother, Louise of Savoy, was walking, when she was taken with the pangs of childbirth, and, being unable to return to the castle, was delivered under the tree. An enclosure of masonry surrounded the spot; but the tree has decayed, and been replaced by another, planted in its stead, and the enclosure has been destroyed in order to widen the road. Cognac had, in 1832, 3101 inhabitants for the town, or 3409 for the whole commune. It is a busy place, the centre of the trade carried on for the brandy of the surrounding district. Leather, paper, and porcelain, are also manufactured; and near the town is a quarry, which supplies abundance of gypsum. There is a high school, and an agricultural society.

Confolens is on the right bank of the Vienne, at the confluence of the little stream, the Goire, with that river. The banks of these streams afford good pasturage, in which many oxen are fattened; but the neighbourhood is generally sterile. There is a lead mine not far from the town. Confolens has a square tower, the only remaining part of the old castle. The population in 1832 was 2215 for the town, or 2687 for the whole commune.

Ruffec is on the great road from Paris, through Angoulême, to Bordeaux, 29 miles from Angoulême: it is on a small rivulet, containing excellent trout, which runs into the Charente, and is not far from the right bank of the latter river. It is a pretty town, well laid out in the midst of a district producing grain and grapes. The population in

1832 was 2749 for the town, or 3004 for the whole commune. This place has a considerable reputation for good cheese, higher perhaps than is deserved. The neighbourhood produces some truffles, but not any great quantity.

La Rochefoucauld is on the road from Angoulême to Limoges, 15 miles from the former, on the banks of the Tardoire, at the end of a long street, and is commanded by the ancient castle of the dukes of La Rochefoucauld. The author of the well-known *Maxims* was born in this castle. There is an hospital, founded by one Gourville, originally a servant of one of the dukes, who came to be considered as the friend of his master, and of the great Condé. The castle, which consists of four round towers, and a square tower (the donjon, or keep) of greater antiquity than the rest, was employed in 1812 as a public school: the park was then a public promenade. The inhabitants in 1832 amounted to 2403 for the town, or 2706 for the whole commune. They manufacture linen yarn, and leather.

Jarnac is chiefly remarkable for the battle fought under its walls in 1569, in which the Catholics under the duke of Anjou, afterwards Henry III., defeated the Huguenots under Coligny and the prince of Condé, the latter of whom was taken prisoner, and killed in cold blood by the marquis de Montesquieu, captain of the guard to the duke of Anjou. A monument, erected to commemorate the battle, was destroyed some years ago; but a new one has been erected. The population of the town in 1832 was 1850, of the whole commune 2282. A considerable trade in brandy is carried on.

Mansle is a small town, having (in 1832) a population of 1500, or 1785 for the whole commune. It is on the high road from Paris to Angoulême, about 17 miles from the latter. Upon entering the town from Paris, the traveller crosses the Charente by a lofty stone bridge, from which the river is seen on each hand meandering through beautiful meadows.

Aubeterre, a small town in the southern part of the department, is remarkable for its picturesque situation at the foot of a hill on the banks of the Dronne. There are the remains of an old castle; but the most singular object is the church, which is excavated in the hill on which part of the castle stands. The population, according to the *Dict. Universel de la France* (Paris, 1804), our latest authority, was under 700.

Among the articles of manufacture in this department may be noticed the paper of Angoulême, the linen of Barbezieux, and the leather of Rochefoucauld.

The department of Charente constitutes the diocese of Angoulême, the bishop of which is a suffragan of the archbishop of Bordeaux. It is under the jurisdiction of the Cour Royale, or Assize Court of Bordeaux, and is comprehended in the twelfth military division, of which Nantes is the head quarters. It sends five members to the Chamber of Deputies. (Malte Brun, Balbi, Vayssé de Villiers, Milin, *Encyclopédie Méthodique*.)

CHARENTE INFÉRIEURE, or LOWER CHARENTE, a department of France, watered by the river Charente in the lower part of its course; from this river it takes its name. It comprehends the greater part of the provinces of Saintonge and Aunis. It is of an irregular form; and is bounded on the N. by the department of Vendée; on the N.E. by that of Deux Sèvres; on the E. by the department of Charente; on the S. and S.W. by the department of Gironde; and on the W. by the sea. It comprehends the three islands of Ré, Aix, and Oléron. The greatest length of the department is 98 miles, measured N.N.W. and S.S.E.; its greatest breadth, measured nearly at right angles to the length, is about 57 miles. The length of the sea coast is about 77 miles, exclusive of the islands; and the banks of the wide estuary of the Gironde extend for about 24 miles farther. The department is about 2346 English square miles (according to M. Balbi), nearly equal to that of the English counties of Dorset and Wilts. taken together. The population in 1832 was 445,249; or 190 to a square mile. The capital, La Rochelle, is about 40 miles in a direct line, S.W. of Paris, or 301 miles by the road, through Orléans, Tours, Poitiers, and Niort.

The department of Charente Inférieure has no very high lands; the hills are inconsiderable, and the plains extensive; the sea coast is low, and salt marshes furnish an abundance of good salt. From the midst of these marshes, spots of land are slightly elevated to keep them from being inundated.

arise, and have obtained in France, as in England, the designation of 'Isles.' (*Encyc. Méthod.*, art. Aunis.)

The rivers which water the department are the Charente and its tributaries, the Seugne, the Boutonne, the Soudre, and the Sèvre. The Charente is navigable throughout the department, the Boutonne from St. Jean d'Angély. The Soudre rises in the southern part of the department, near St. Genis, a little town on the road from Saintes to Bordeaux, and, flowing to the N.W., falls into the sea opposite the île of Oléron. Though its whole course is very short, not more than 45 miles, it is navigable for twelve or fifteen miles, from the little town of Saujon to the sea. The Sèvre has part of its course just within the northern boundary of the department, throughout which it is navigable: the navigation commences at Niort, in the department of Deux Sèvres. The south-western side of the department is washed by the Gironde, which separates this department from that of Gironde.

The coast is indented by the bays of Pertuis Breton, and Pertuis d'Antioche, which are sheltered to the S.W. by the îles of Ré and Oléron respectively, and form good roadsteads. The navigation is however impeded or endangered by rocks and sands, which extend far beyond low water mark round the islands above mentioned; the coast generally declines very gradually. Oysters and sardinias, a species of pilchard, abound on the coast.

Besides the navigable rivers above mentioned, a canal, called the canal of La Rochelle, extends from the Sèvre to the town of La Rochelle. The high roads from Paris to Rochefort (a road of the first class), and La Rochelle (a road of the second class), traverse the department in the northern part; and the great road from Paris to Bordeaux just crosses it in the S.E. Of roads of the third class there are several; three coming respectively from Niort, Lusignan, and Angoulême, unite at St. Jean d'Angély; one runs from La Rochelle to Rochefort, and another to St. Jean d'Angély; one from this last-named town, and one from Rochefort, unite at Saintes; from whence again two other roads run, one by Cognac to Angoulême, another by Blaye to Bordeaux. The department may be considered as better supplied with the means of communication by land and water than the average of France. To this advantage, combined with the excellence and number of the ports and roadsteads, may be ascribed probably the denser population of this department, as compared with that previously described. The colonial and the coasting trade, especially the latter, are carried on with considerable activity; and the inhabitants of the coast are also engaged in the cod fishery. The low marshes about the coast render that part of the department however very unhealthy; the air of the inland country is salubrious enough.

The tracts watered by the Charente are productive in corn, and in wine; the latter is chiefly converted into brandy. There is good pasturage also.

The department of Charente Inférieure is divided into six arrondissements. Those of La Rochelle, population 77,589, and Rochefort, population 48,836, in the N.W.; that of St. Jean d'Angély, population 80,173, in the E.; that of Marennes, population 49,156, in the W.; that of Saintes, population 104,933, in the centre; and that of Jonzac, population 84,562, in the S.

The chief towns are La Rochelle, the capital of the department, on the sea, population in 1832, 14,632; Rochefort, a royal dock-yard and naval port, population 10,332 for the town, 14,040 for the whole commune; Saintes on the Charente, population 7521 for the town, 10,437 for the whole commune; and St. Jean d'Angély on the Boutonne, population 5326 for the town, 6031 for the whole commune. [JEAN D'ANGÉLY, ST., ROCHEFORT, ROCHELLE, SAINTES.]

Marennes is about a mile from the sea, is well-built, and for its size and population a busy and wealthy place. The population, in 1832, was 1969, but the whole commune contained 4605. The neighbourhood produces a great quantity of brandy, which is sent into Picardie, Flanders, and the north of Germany; the peas and beans are also accounted excellent. There are considerable oyster-beds, and much salt is made from the brine of the salt-marshes. Marennes would probably be a place of much greater importance were not its increase checked by the unhealthiness of the situation. The neighbouring town of Brouage, which was, in 1606, the seat of an extensive commerce, has been reduced by the operation of the same cause to insignificance.

on the Seugne, a tributary of the Charente, had, in 1832, a population of 1798 for the town, or 2618 for the whole commune; its consequence is derived from its official rank as the chief town of an arrondissement.

Marans is on the south or left bank of the river Sèvre, a few miles above its mouth, and about 14 miles N.E. of La Rochelle. It is in the midst of salt-marshes, and is almost inaccessible in the rainy season. It has sustained several sieges, and was taken in 1588 by Henry IV. There was a castle, which was raised in 1638. The population, in 1832, was 2770 for the town, or 4041 for the whole commune. There is a quay to which vessels of 100 tons can come up with the tide. The inhabitants manufacture good earthenware, and procure much salt from the marshes. A very considerable trade in corn and flour is also carried on, as well as in brandy, hemp, flax, wool, ship timber, and tress.

St. Savinien is on the right bank of the Charente, between Saintes and the confluence of the Boutonne with the Charente. The inhabitants, who, in 1832, were 2465 in the town, or 3559 in the whole commune, carry on trade in brandy, grain, and pottery-ware. Good white building stone, suitable for almost any kind of work, is quarried; and mussels of considerable size are fished, which frequently contain pearls of some value.

La Tremblade is near the sea, just to the south of the river Soudre. It had, in 1832, 2400 inhabitants for the town, or 2504 for the whole commune. The chief trade carried on is by sea, and the articles of commerce are salt, wine, brandy, and vinegar. The *Dict. Universel de la France*, 1804, mentions glass as an article manufactured here.

Pons is on the road from La Rochelle, by Rochefort and Saintes, to Bordeaux, about 56 miles from La Rochelle, and 12 S. of Saintes. It is supposed to owe its name to the numerous bridges which here cross the little river Seugne, a tributary of the Charente, on which the town stands. It has an ancient castle, which commands the town; and before the revolution had three churches, three hospitals, and a commandery of the Order of Malta. It is divided into two parts; the upper town or St. Vivier, and the lower town, or Aires or St. Martin. Pons was a place of some importance in the feudal ages; and was one of the fortified towns of the Huguenots, in their struggle against Louis XIII. and his minister Richelieu. Population, in 1832, 2275 for the town, 3726 for the whole commune.

Tonnay Charente is on the Charente, about 5 or 6 miles from Rochefort. It is a town of considerable antiquity, and a castle was formerly in the hands of the family of Mortemare; the eldest son of the duke of Mortemare bore the title of 'Prince of Tonnay Charente.' Its harbour admits vessels of 100 tons, and it is the centre of a considerable trade; nearly all the Cognac brandy that is sent to England is exported from here. Salt is made also in the neighbouring marshes. Population, in 1832, 1791 for the town, 3206 for the whole commune. Tonnay Boutonne is a small town on the Boutonne, between Rochefort and St. Jean d'Angély.

Royan is on the coast, just to the south of the river Gironde. The population in 1832 was 1695 for the town, or 2589 for the whole commune. It has a small harbour, convenient for small vessels. The fishermen take great quantities of sardinias, which are in high repute for their size and goodness. This town was held by the Huguenots in the religious dissensions of the reign of Louis XIII., and was not taken by that prince's army without considerable difficulty. After its capture the fortifications were raised, and a considerable part of the town destroyed. The country around is fertile and agreeable.

Surgeres is on the road from Paris to Rochefort, 17 miles from the latter. The inhabitants, who in 1832 were 1683 for the town, or 1979 for the whole commune, carry on trade in horses, sheep, and oxen, white wine, and brandy. There is an ancient castle.

Brisembourg, a village on a bye road from St. Hilaire, near St. Jean d'Angély, to Cognac, is known for its pottery; and Mirambeau, 27 miles S. of Saintes, and Cozes, between Pons and Royan, have a considerable trade in agricultural produce; the former in grain, fruit, and wine; the latter in mules. Saintes appears to be the chief manufacturing town in the department; light woollen goods, hosiery, and leather are made there. Sugar is refined at La Rochelle. The chief places of trade in brandy, which may be considered as the staple of the department, are La Rochelle, St. Jean d'Angély, Saintes, and Tonnay Charente. Rochefort is one of the great naval ports of France. La Rochelle was the

strong-hold of the Huguenot party, until they were humbled by the power of the Crown and the ability of Richelieu.

The Isle of Oléron extends about 20 miles in length from N.N.W. to S.S.E.; and about 3 miles in breadth. (Brue's *Map of France*.) It is nearly surrounded by shoals, and a ledge of rocks runs along a considerable part of the S.S.W. coast toward the open sea; there are rocks also about the northern point. Oléron is separated on the S.E. side from the main land by the narrow strait, *Passe de Mamusson*, and on the N.E. by the bay of Pertuis d'Antioche, which also separates it on the N. from the Isle of Ré. This island was called by the Romans *Uliarus*, which name occurs in Pliny; at a later period we find, in Sidonius Apollinaris, the derived adjective *Olurionensis*, which serves to mark the transition to the modern name of Oléron. The soil of this island is calcareous, and fertile in corn and wine, and its salt-marshes yield much salt. It contains about 16,000 inhabitants. The little town of Oléron is on the E. side of the island, opposite to the main land; it contains about 3000 inhabitants, and is defended by a strong castle. Salt, wine, and brandy, the staple productions of the island, constitute the chief articles of the trade of the town, which was once deemed of sufficient importance to be the seat of a bishopric. The town of St. Pierre d'Oléron is situated near the centre of the island, and had in 1832 a population of 4630 for the whole commune. At the north end of the island is the tower of Chassiron, where is a lighthouse to guide vessels by night into the Pertuis d'Antioche.

The Isle of Ré is about 16 miles in length, from W.N.W. to E.S.E., and about 3 or 4 miles in breadth. The Pertuis d'Antioche separates it on the S. from the Isle of Oléron and the Pertuis Breton, and a strait which connects these two bays separates it on the N.E. and E. from the main land. It is nearly surrounded by rocks and shoals. We do not meet with any mention of this island by name in the Roman writers; The anonymous geographer of Ravenna calls it *Ratis*; in the middle ages we meet with it under the name *Radis*. The climate of the island is mild and temperate; the soil is every where sandy, and destitute of water. The island contains neither spring nor brook, and the only water the inhabitants can obtain is sea water, filtered through the sand. This they procure by merely digging to the depth of three or four feet; but it has not lost its acidity and saltiness, and those who have not been accustomed to drink it find difficulty in reconciling themselves to it at first. The island has neither wood nor pasturage; some cows are kept, which are fed upon a plant which grows along the shore under the water, and which is gathered and dried for fodder. Little grain is grown in the island, though barley and oats succeed tolerably well. A considerable quantity of white wine of middling quality is produced, and much brandy distilled. The principal fruits cultivated are figs and almonds. The population of this island is probably nearly equal to that of Oléron.

The coasts of the island present a succession of well-sheltered bays, roads, and harbours, of which the best are those of St. Martin, Ars, and La Flotte. St. Martin d'Ré has a square citadel, fortified with bastions and other works, which defends the harbour and the town. Though the town is small, it is well-built and handsome. It has a fine arsenal and a military hospital. The inhabitants in 1832 were 2499 for the town, or 2581 for the whole commune; they trade in salt, wine, brandy, and vinegar; and in deals (planches), which last are imported by the Prussians or Dutch; they are engaged also in the cod and thornback fishery. Ars had in 1832 a population of 2410 for the town, or 3875 for the whole commune. The adjacent marshes yield salt, and in the neighbourhood are collected transparent pebbles, white, yellow, brown, and rose-coloured, which yield not in brilliancy to the pebbles of Médoc. La Flotte had in 1832 a population of 2452 for the town, or 2557 for the whole commune.

The Isle of Aix is very small; it lies in the Pertuis d'Antioche, between the Isle of Oléron and the main land. It contains about 200 or 300 inhabitants, but it is fortified. A French fleet of nine or ten sail of the line, lying off this island, was attacked in the evening of the 11th April, and on the 12th April, 1699, by a squadron of British frigates, fire-ships, and other vessels, under Lord Cochrane, detached from the British fleet under Lord Gambier. Three ships of the line were taken and destroyed, and another ship of the line was destroyed by the French, to prevent capture; some other vessels were driven on shore.

The Isle of Madame at the mouth of the Charente is also fortified.

The department of Charente Inférieure constitutes the diocese of La Rochelle. It is in the jurisdiction of the Cour Royale, or Assize Court, of Poitiers; and in the twelfth military division, of which Nantes is the capital. It sends seven members to the Chamber of Deputies. (Malte Brun; Balbi; *Encyclopédie Méthodique*; *Dictionnaire Universel de la France*.)

CHARENTON, a small town (*bourg*) in France, in the department of Seine, about two miles from the barriers of Paris; it is on the right bank of the Marne, just above its confluence with the Seine. A bridge, partly of stone and partly of wood, connects it with the village of Ablon on the opposite bank. Charenton is pleasantly situated, and contains several country houses, and a building called *Le Château*, once the residence of Gabrielle d'Estrees, mistress of Henry IV., built for her by that king. The population, in 1832, was only 1925 for the town, or 1501 for the whole commune. There is an extensive iron foundry and manufactory of cylinders for cotton-printing.

The bridge of Charenton has always been regarded as one of the keys of Paris on that side, and has consequently been an object of contest in the wars of the French, foreign or domestic. In the contests with the Normans in the ninth century, and with the English in the fourteenth and fifteenth; in the war of the *Ligue du Bien Public*, League of the Public Weal, against Louis XI., of the Huguenots and Catholics, of Henry IV., and the Leaguers, possession of it was disputed. A tower near this bridge was defended in 1590 against Henry IV. by ten Parisians, whom, upon their surrender, the king hung. In the battle of Paris, March, 1814, this bridge was bravely but unsuccessfully defended by the pupils of the veterinary school of Ablon.

When the edict of Nantes, March, 1598, guaranteed to the Protestants the full exercise of their religion, those of Paris were allowed to have their place of worship at Ablon, a village on the bank of the Seine, several miles south of Paris; but the distance being inconveniently great, they were allowed, in 1606, to remove their worship to Charenton. It was commenced August 27, that year; the Protestants assembled to the number of 3000, and the violence of the mob, who were excited against them by the Catholic priests, was restrained by a body of archers sent by the king to protect the worshippers. The Protestants were continually, however, exposed to insult and violence. In 1621 the congregations returning from Charenton were attacked by a set of armed robbers and other vagabonds, instigated by some secret enemies of the Protestants; the minister was maimed, several persons were killed, and their place of worship was burnt.

The Protestant church was rebuilt on a large and more magnificent plan, and finished in 1623, when the Protestants held their national synod there. Its inside dimensions were 104 feet by 66. There were near it a library, a printing-office, and booksellers' shops, principally intended for the printing and sale of their religious publications. In August, 1685, a new attempt was made by the mob on this church; two shops adjoining to it were burnt, and the church itself narrowly escaped. Upon the revocation of the edict of Nantes, a few weeks afterwards, the demolition of all the Protestant churches remaining in France was ordered; the demolition of that of Charenton was commenced the very evening of the day on which the Act of Revocation was registered, and, in five days, the church was entirely destroyed, the library, printing-office, and minister's house sharing the same fate. The materials were given to the Hôtel Dieu, at Paris. The celebrated Jean Claude, whose talents caused him to be regarded as the head of the Protestant party in France, was minister of Charenton at the time of the suppression of the Protestant worship.

There is at Charenton an asylum for pauper and other lunatics. The establishment originated in 1741; it was founded by one Sebastian Leblanc, and was under the management of the *Frères de la Charité*; but it has since been modified and enlarged. The number of patients is now above 400. The treatment is peculiar; the influence of music and of dramatic entertainments in which the parts were sustained by patients who had lucid intervals, has been tried.

CHARLES Alexander the Great

Master of the Ceremonies to a collection of anecdotes, or of the private life and an-

ventures of the king. We may judge from the fragments in Athenæus that this work contained numerous details which were exceedingly curious and interesting. (Athenæus, *Deipn. Cassan.*)

CHARGES. (Russo.)

CHARGE, in the practice of artillery, denotes the quantity of powder placed in a gun, howitzer, or mortar, for the purpose of expelling the shot or shell by its explosion.

The service-charge varies from one-sixth to one-third of the weight of the projectile: the lower charges being used in the field, or in naval actions; and the higher in breaching the walls of fortresses. It is evident that extensive ranges and great velocities of shot are not required when artillery is directed against an enemy's columns or lines; and it is found by experiment that a ball which just pierces the timbers of a ship will fracture them more than if it passed rapidly through them. On the other hand, the greatest momentum is necessary on commencing the formation of a breach in a rampart faced with brick or stonework, as the depth to which the shot will penetrate is thereby increased, and therefore the highest charges are then required.

According to Dr. Hutton (*Treatise*), different charges of powder, when the weight of the ball remains the same, produce velocities which are as the square roots of the weight of powder; and, when the weight of powder is the same while that of the ball varies, the velocities are inversely proportional to the square roots of the weight of the balls. The Doctor states, also, that the greatest velocities are produced in guns, the lengths of whose bores are equal to fifteen, twenty, and thirty calibres, or diameters, by charges occupying $\frac{1}{15}$, $\frac{1}{20}$, and $\frac{1}{30}$ of the lengths of the bores respectively; and he adds, that by increasing the quantity of the charge, the velocities increase till they amount to a certain value, after which they decrease till the bore is quite filled with powder. The charge producing the maximum velocity is greater as the gun is longer; but it does not increase in so high a ratio as the length of the gun.

CHARGE D'AFFAIRES, one who transacts diplomatic business at a foreign court during the absence of his superior, the ambassador. The agents that bear this name also form a separate class, being the chosen envoys or residents at the states to which other states do not appoint diplomatists of the higher grades. In this capacity the *Chargés d'Affaires* act for themselves, represent their country, and are independent of any ambassador. In the ordinary routine and course of promotion, the secretary of legation, or secretary of embassy, becomes a *Chargé d'Affaires*, but individuals are not unfrequently elected on other grounds of fitness or ministerial patronage, and without having gone regularly through the subordinate grades of the profession. It now seems to be the practice to appoint *resident ministers* (a class above *Chargés d'Affaires*, but beneath envoys, ordinary and extraordinary, and ministers plenipotentiary) rather than *Chargés d'Affaires*. In this year (1838) the only British *Chargé d'Affaires* on the diplomatic list is one to Mexico. In the article 'Ambassador,' the gradations of diplomatic rank and etiquette are fully explained.

CHARIOT, a light sort of coach; also, a car, in which men of arms were placed in fight. The name is derived from the French word *charrette*. Cars or chariots are of very early use. The invention of them was attributed by the Greeks to Minerva (*Hymn. in Ven.* v. 12), on which account she was venerated at Athens and various other places in Greece under the name of Hippias: and the honour of the invention was shared by Erichonius, who, according to Virgil, was supposed to have first harnessed horses to a car, and to have introduced chariot-races at the Panathenæa, which were established by him.

The most ancient war-chariots we know of are those of Pharaoh, which were overwhelmed in the Red Sea. (*Exod.* xiv. 7.) The Canaanites whom Joshua engaged at the waters of Merom had a multitude of chariots. (*Josh.* xi. 4.) And the Philistines, in their war against Saul, are stated (*1 Sam.* xiii. 5) to have had thirty thousand.

Chariots armed with scythes were in use for many ages in all the Eastern countries; and were regarded as a principal arm of war. Such are mentioned in the Second Book of Maccabees (ch. xiii. v. 2), which the king of Syria led against Judæa. They were used by the Persians, as we see from Xenophon (*Anab.* i. 8), and they constituted a remarkable feature in the armies of the ancient Britons.

Cæsar (*De Bell. Gall.* v. 19) says, that after Cassivellaunus had dismissed all his other forces, he had still four thousand of these war-chariots about his person. See Cæsar's account of the method used in fighting with them (iv. 33).

The Easedum and the Rheda were among the Roman war-chariots of the larger size. Greek and Roman chariots frequently occur on the reverses of medals.

CHARITÉ, LA, a town in France, in the Department of Nièvre, on the right bank of the Loire, between Nevers and Cosne. It is 119 miles from Paris, in a straight line S. by E., or 126 miles by the road through Fontainebleau, Montargis, Briare, and Cosne: and 14 or 15 miles from Nevers, the capital of the department. It is in 47° 11' N. lat., and 3° 2' E. long.

This town is built near the site of a more ancient one, which had the name of Seyr. About the year 1000 a powerful noble built and endowed a monastery on the bank of the Loire, near this town of Seyr; and the town of La Charité, which took its name from the abundant alms of the religious, rose round this monastery and caused the downfall of its more ancient neighbour. Within a century after its foundation the rising town twice attracted the cupidity and experienced the violence of a barbarous tribe, whom Ekpilly designates as Vandals. In the religious wars of the sixteenth century, it was pillaged and burnt by the Huguenots, to whom it was betrayed by some of the inhabitants, and abandoned by the governor.

Before the Revolution, there were several religious houses in the town; the Benedictine Priory of the order of Cluny was richly endowed; the building was one of the finest in the kingdom, and the prior was spiritual and temporal lord of the town.

La Charité has well-built houses, and a pleasant public walk on the banks of the river; there is also a good bridge over the Loire, across which the road to Bourges passes, and a fine Gothic church in ruins.

The population in 1832 was 4480 for the town, or 5086 for the whole commune. The chief manufactures are of iron, steel, and other metal goods, especially buttons, buckles, helmets, bayonets, and side arms. Some woollen cloths are made, also glass and earthenware. The articles of trade, beside the foregoing, are wood and hats.

CHA'RITON, the author of a Greek romance, in eight books, entitled 'The Loves of Chaereas and Callirhoe.' The writer calls himself Chariton of Aphrodisias: the time at which he lived is uncertain, but probably not earlier than the fourth century of our æra. Though this, like most other Greek romances, displays little invention, it has some merit in point of style. Chariton was published by D'Orville, Amsterdam, 1750, 3 vols., 4to., with a valuable commentary. It is translated into German by Seidel, Leipzig, 1806, 8vo.; and into French by Larcher.

CHARKOW (pronounced Kharkoff), a town in southern Russia, in 50° N. lat., and about 33° 30' E. long., between two small rivers, the Charkowa and the Lopan, which fall into the Dneez, one of the largest tributaries of the Don. Charkow is the capital of the government, now called Slowodesk Ukraine, but formerly the government of Charkow, and may be considered as being placed on the boundary-line between the fertile country which extends over the centre of Russia, and the large deserts known under the names of steppes, which occupy the southern districts of the empire. This town, which contains about 18,000 inhabitants, has been chosen by the Russian government as the centre of instruction for the southern provinces. The university, which was erected in 1803, was attended in 1831 by 318 students. Connected with it is a botanic garden, a collection of natural objects, an observatory, and a library of 20,000 volumes. There is also a seminary for clergymen, a military academy for forty children of poor noblemen, a grammar-school, and an institute of education for young ladies, with some other schools. In modern times a philotechnic society has been erected, whose object is the establishment of manufactures in this part of Russia. There is more industry in this town than in many others of Southern Russia; but it is almost exclusively limited to *shenkie* (coats of Cosacks), *charumars* (trowsers of Cosacks), and *cozie* (carpets and cloaks made of felt). This branch of industry supplies the principal articles of sale at the fair fairs which are held annually at this place, and are visited by many merchants from the interior of Russia.

CHARLEMAGNE, KARL DER GROSSE, or Charles the Great, son of Pepin le Bref, king of the Franks, and of

Bertha, daughter of Caribert, Count of Laon, and grandson of Charles Martel, was born about 742 in the castle of Salzbürg in Bavaria, a country which Pepin had conquered, as well as part of Saxony. Pepin died in 768, and Charles and Carloman, his sons, succeeded to the vast dominions of the Franks. Charles had Austrasia and Neustria, with part of Germany; Carloman had Burgundy and South Gaul. Carloman died in 771, leaving two infant sons, but Charles possessed himself of his dominions; and Carloman's widow, with her children, took refuge at the court of Desiderius, king of the Longobards. Charles was now sovereign of the whole Frankish monarchy, which extended not only over the present France, but also over nearly one-half of Germany. The Franks were still, in a great measure, a German nation; and the native language of Charles was a dialect of the Teutonic. In 772 Charles began his wars against the Saxons, which continued with various interruptions till 803. Witikind, the principal chief of the Saxons, a cunning and brave barbarian, gave him full employment for many years. The Saxons were Pagans, and Charles and his Franks seem to have felt little scruple in massacring them by thousands, even after they had laid down their arms. In 774 Charles being applied to by Pope Adrian I. against Desiderius, king of the Longobards, who threatened Rome, hastened from Germany to Italy, crossed the Alps by the pass of Susa, defeated Desiderius at Pavia, and took him prisoner. He assumed the crown of Lombardy, and confirmed Pepin's donation of the Exarchate of Ravenna and the Pentapolis to the Pope, who on his part acknowledged Charles as Patrician of Rome and Suzerain of Italy, with the right of confirming the election of the popes. In 775 Charles proceeded again to Germany against the Saxons. In the following year he returned to Italy to quell some insurrections; in 778 he went to Spain against the Saracens, and conquered part of Catalonia, Aragon, and Navarre; but on recrossing the Pyrenees, his rear guard was defeated at Roncesvalles by the Vascones and the Saracens united. Several nobles of Charles's court fell on that day, among whom was Roland, warden of the borders of Brittany, 'Præfectus Britannici Limenis,' who has become the hero of many a romantic tale. In 780 Witikind having defeated several bodies of Franks, Charles found it necessary to visit Germany again in person; and after several sanguinary campaigns, Witikind was obliged to submit and receive baptism. The alternative of death or Christianity was held out to thousands of the Saxons, who generally preferred the latter; and Charles, by transplanting whole colonies of them into remote parts of France or Italy, broke their strength. Tassilo, Duke of Bavaria, a feudatory of the Frankish monarchs, having assisted or connived at Witikind's incursions, Charles invaded Bavaria, and brought the duke before the diet of the great lords assembled at Ingelheim, where Tassilo was found guilty of treason and condemned to death. Charles spared his life, but had him confined in a convent in 794. As for Witikind, he lived the rest of his days in peace, on his domains in the north of Germany, and his posterity is said to be present in the House of Oldenburg, the stock of the present reigning houses of Denmark and Russia. (Dunham's *History of the Germanic Empire*.) In the year 800 Charles being victorious everywhere, and master of the best part of Europe, visited Rome, where he was solemnly crowned Emperor of the West by Pope Leo III., with the title of Carolus I. Cesar Augustus. He was called by the historians Carolus Magnus, from which the French have made Charlemagne; German writers call him Karl der Gross. Nicephorus I., Emperor of Constantinople, sent an embassy to Charles by which he acknowledged him Emperor of the West, with the title of Augustus, defining at the same time the limits between the two empires, which seem to have been the Raab in Hungary, and the mountains of Carniola down to the Gulf of Syria; and in Italy, the old boundary between the duchy of Benevento, and the Greek possessions in Apulia and Magna Græcia. Charlemagne had therefore Germany, the Netherlands, the Gauls, the greater part of Italy and Spain as far as the Ebro, with the Balearic islands, Corsica and Sardinia. He was on good terms with the Saxon kings of Britain. The caliph of Bagdad sent embassies to him. From the Ebro to the mouth of the Elbe, from the Atlantic to the mountains of Bohemia and the Rhine, and from the British Channel to the Vistula, was the extent of his dominions. Bohemia, which was then inhabited by Slavonian tribes, he

never subjugated. About 807 or 808, the first mention occurs in history of the Normans and Danes making descents on the coast of France. Charlemagne seems to have felt the danger of this new enemy, for he took great pains to fortify the extensive coast line of his dominions; he stationed armed vessels in every harbour, and made Boulogne one of his principal naval stations. In 813 Charlemagne named his third son Louis, called afterwards Louis le Débonnaire, his colleague in the empire. He had lost his two elder sons, Pepin and Charles, but he appointed Bernard, the son of Charles, king of Italy. In January, 814, Charlemagne died of pleurisy at Aix-la-Chapelle after a reign of forty-seven years. He was buried with great pomp in the cathedral at Aix-la-Chapelle.

Charlemagne may be considered the principal regenerator of Western Europe after the destruction of the Roman empire. He was ambitious, but his was of an enlarged kind, and led to not merely a successful legislator; and his when contrasted with He was the first to the turbulent Franks; he effected the subordination of his vassals, which his unable to subdue. He was the of the Germanic empire, having transformed tribes of lawless barbarians, such as the Saxons, the Bavarians, the Frisians, &c., into a federation of civilized nations. His predecessors, Charles Martel and Pepin, had checked the advance of the Saracens on the side of the Pyrenees; Charlemagne drove them back beyond the Ebro. His overthrow of the Longobards in Italy has been viewed in various lights by party historians. He has been considered by some as having, by his alliance with the popes, favoured the encroachments of their spiritual power over temporal affairs. But it ought to be observed that in his life-time at least he always asserted the superiority of the empire over the church in temporal matters, that he crowned himself king of Italy, and that even at Rome the laws were proclaimed in his name, 'Imperante Domino nostro Carolo,' and the coin bore his stamp. Other writers have assumed that the overthrow of the Longobards was a misfortune to Italy, because they have fancied that their power was likely to effect that union of the Peninsula which has been the favourite vision of the Italians in all ages. But that union, had it been possible, was more likely to be effected by a sovereign like Charlemagne, who ruled singly and firmly over his vassals, and who was acknowledged as emperor of the West and successor to the Cæsars, than by an elective king like that of the Longobards, who was every moment at variance either with some one of the numerous dukes, who ruled absolutely each his respective territory, or with the Greek emperors, who still retained nearly one half of Italy. Besides, it ought not to be forgotten that the Longobards, even under their best kings, always retained a broad distinction between themselves the conquerors, and the Romans or conquered race. This humiliating and often oppressive distinction Charlemagne abolished, and by so doing he in fact emancipated the original Italian population from bondage. Those who may wish to look further into this often misstated question will find a sober and argumentative discussion of it in Manzoni's *Discorso storico sopra alcuni punti della Storia Longobardica in Italia*, which accompanies his historical drama of Adelchi. Charlemagne promoted instruction by the only means then known, by founding monasteries and endowing churches with schools attached to them. He enacted a series of regulations upon civil and ecclesiastical matters which may be considered as forming a code of laws. [CAPITULARIES.] He often assembled diets of the great lords and bishops, and consulted them upon important matters, thus showing a deference to the opinion of the only classes that had then any pretensions to education. Upon the clergy as being the only men of that age. As Paulus Diaconus, and ed men, were known with his favour. He was easy of access to the humble and poor, and showed himself just and merciful towards them. He was on the contrary, at times harsh and cruel to his nobles and to his ambitious subjects, whom he treated the same manner, that they treated their of his first wife was Her-

are all so near together that the whole may come from one spot. Every thing required for building and setting these works in action is found on the spot, with the exception of clay for making bricks, which is brought from India. When the whole of these furnaces shall be in action, it is estimated that they will produce about 100,000 tons of iron per annum, and employ about 3000 workmen.

The district presents great facilities for water-carriage, and in a short time Charleroy will be connected by means of railroads with most of the principal towns of Belgium: the high roads from Brussels, Mons, and Namur meet at Charleroy.

CHARLEROY, CANAL OF. [BRUSSELS.]

CHARLES I., King of England, the third son of James I. and Anne, daughter of Frederick II., King of Denmark, was born at Dunfermline, in Fifeshire, North Britain, on the 19th of November, 1600. James's second son, Robert, having died in infancy, and his eldest, Prince Henry, in his nineteenth year, in 1612, Charles became heir-apparent to the crown. He was not, however, created Prince of Wales till the 1st (before that authorities say the 4th) of November, 1616. His title before this was Duke of York and Cornwall.

Almost the only transaction in which Charles figured before he ascended the throne was the extraordinary expedition to Spain made at the suggestion and in the company of the Duke of Buckingham, in the year 1623, to conclude in person the negotiations for his marriage with the Infanta Maria, a business which had occupied his father for nearly the preceding seven years. The affair was probably, prevented from being brought to the intended conclusion by this very journey. After it was broken off, Charles and his father directed their views to a French match, the negotiation for which was in progress when James died, on the 27th of March, 1625. The new king's marriage with the Princess Henrietta Maria, the youngest daughter of Henry IV., was solemnized by proxy, at Paris, on the 11th of May.

At the accession of Charles, circumstances and the minds of men were ripe for a renewal of that struggle between the popular and the monarchical principles of the constitution, which his predecessor had with difficulty put down, when it broke out in the parliament assembled in 1620. Charles began his reign by retaining as his chief adviser his father's favourite, the unpopular, unprincipled, and incapable Buckingham. At the same time the difficulties in which he was involved by the war that had just been entered into with Spain, offered to the popular party an opportunity of pursuing their objects, which seemed too remote to be neglected.

The reign commenced accordingly with a contest between the king and the parliament, the latter firmly refusing to grant the supplies demanded by his majesty until they had obtained both a redress of grievances and a limitation of the prerogative. Charles on his part met the resistance of the parliament both by insisting upon preserving the prerogative entire, and by boldly putting it in force. In the course of this first contest three parliaments were successively called together and dismissed. The first met 13th June, 1625, and was dissolved 12th August, in the same year; the second met 6th February, 1626, and was dissolved, before it had passed a single act, 16th June; the

third met 17th March, 1628, was suddenly prorogued 25th June, and was called 26th January 1629, and was finally dissolved 10th March of the same year. All this time the proceedings of the king continued to be of the most arbitrary character. Money was collected from the people by the influence of the crown was exercised in a manner to overawe the judges, in charges in which the liberty of the subject was concerned; the first principle itself was violated by the mixture of the House of Commons; and their proceedings to punish the king were carried on by them in debate.

Charlmont
is rather in
Paris, or 163 miles
30° S. N. lat. and

Charlemont is a place of model fortification; it was originally a fortress, built by the Emperor Charles V., and united by him, in the year 1535, to the territory of Namur. It derives its name from its founder, and from its situation on a steep eminence. By the treaty of Nimeguen, in 1678, it was ceded to France, and Louis XIV., desirous of enlarging the fortress, caused the adjoining villages or towns of Givet, one lying at the foot of the hill on which Charlemont was built, the other on the opposite bank of the river, to be fortified. The fortifications of Charlemont are partly of the time of Charles V., but the fortifications of Givet, and the out-works of the whole, are by Vauban. The whole constitute a fortress of the first class.

The town of Charlemont is small and of irregular form, but the streets are well laid out, and the houses good. Givet St. Hilaire has a large and well laid out *place*, or open space, and fine barracks. Givet Notre Dume is traversed by the little river Houille, which here empties itself into the Meuse: the circuit of its fortifications comprehends a considerable space, which was not built upon when Exilly wrote (1762), and as the population has not materially increased, is probably still vacant. The two Givets are connected by a bridge over the Meuse.

The inhabitants in 1832 amounted to 4092 for the town, or 4220 for the whole commune. Considerable trade is carried on: the inhabitants manufacture leather, esteemed the best in France, glue, and earthenware; there are several breweries, and a brass-foundry. The situation of the town on the river Meuse is favourable to its commerce, which is however checked by some of the custom-house regulations, which impede the communication of France with Belgium. Châtiment is celebrated for the beauty of the women: indeed the inhabitants generally are handsome.

Maan, the celebrated composer of music, was a native of

CHARLEROY, or CHARLEROI, a town in the province of Hainault, in Belgium, situated on the banks of the Sambre, 29 miles E.S.E. from Mons, and 33 miles S. from Brussels, in 46° 23' N. lat., and 4° 25' E. long. This town, with the whole of Hainault, was united to the French republic, and formed part of the department of Jemmapes. In 1814, it became part of the kingdom of the United Netherlands; and in 1815, during the hundred days, it being in possession of the Prussians, they were attacked by Napoleon, and driven from it a few days before the battle of Waterloo. Since the general peace, the fortifications have greatly improved.

The village is built in the form of an amphitheatre, on the steep hill, which rises from the banks of the river. It contained in 1830, 932 houses, inhabited by 5908 individuals. There is reason to believe that since the last enumeration, the population has increased.
